THE PRINCIPLES OF THE PHILOSOPHY OF THE EXPANSIVE and CONTRACTIVE FORCES.

OR AN INQUIRY INTO THE PRINCIPLES of the MODERN PHILOSOPHY;

THAT IS, INTO THE SEVERAL CHIEF RATIONAL SCIENCES, WHICH ARE EXTANT.

IN SEVEN BOOKS.

By *ROBERT GREENE*, M. A. and Fellow of CLARE-HALL.

CAMBRIDGE:
Printed at the *Univerſity-Preſs*, by CORNELIUS CROWNFIELD, and are to be
Sold by Him, E. JEFFERYS, and W. THURLBOURNE Bookſellers in *Cambridge*, and by J. KNAPTON, R. KNAPLOCK, W. and J. INNYS; and B. MOTTE,
Bookſellers in *London*. MDCCXXVII.

To His GRACE

THE

DUKE OF NEW-CASTLE,

One of His MAJESTIES Principal SECRETARIES OF STATE.

MY LORD,

I Do here moſt humbly beg Leave to Preſent to your Grace my Principles of the Philoſophy of the Expanſive and Contractive Forces, or, my Inquiry into the Modern Philoſophy, and the ſeveral Parts of it, which has been the Labour and Study of many Years, and to which no One has ſo Juſt a Title as your Grace, who formerly Honoured this College with your Reſidence amongſt us, and ſince, with your Patronage and Favour; And it would be no Inconſiderable Reward for the Fatigues, I have Undergone in theſe Matters, if your Grace will Pleaſe to Accept of this Addreſs, as a Teſtimony of that Unfeigned Gratitude and Reſpect, I owe to your Grace, for the many Great Condeſcenſions, which I have formerly Received from You, and of which I ſhall always Retain a moſt Faithfull Memory, Who am,

Your Grace's

moſt Obliged, and moſt

Obedient, Humble Servant,

Robert Greene.

PREFACE.

IT is with the utmoſt Pleaſure and Delight, that I am at Length able to Preſent to the World, after the Labour and Pains of many Years, my Principles of the Expanſive and Contractive Forces, or my Inquiry into Philoſophy and the ſeveral Parts of it, which was begun, even before the Noble Perſon's Admiſſion into the College, I have the Happineſs to be of, to whom theſe Sheets are Addreſſed, and was continued during his Reſidence here, to this Time of its Publication; So far, as the Affairs of the Society, the Buſineſs of my Pupils, and the Studies of my Profeſſion, as a Clergy-Man, would permit.

I ſhall only here Add in Reſpect of my ſelf, in order to Obviate any Calumnies, which may have been Raiſed againſt me, as to my Affection to the Preſent Government, That my firſt Oaths were to King William, *my ſecond to Queen* Ann, *and my laſt to his Late* Majeſty, *and as They are with me of a Religious Nature, ſo I have always Acted Conformably to them, and with the utmoſt Duty and Allegiance, in my private Station, to the ſeveral Princes, to whom I had given my Faith, and called God to Witneſs for my Obedience.*

'TIS *True, as I have had ſeveral moſt Good and ſincere Friends, who come under the Character of Whigs, Tho' I could heartily Wiſh thoſe Names of Diſtinction were entirely Sunk amongſt us, I have alſo had a very Juſt and Deſerved Affection, and Eſteem, for ſeveral of my moſt Worthy Friends, who are under the Denomination of Tories, and particularly, for Two Nonjurors in this Univerſity, whom I could Name; Whoſe great Learning, Piety, and Abilities, have claimed and challenged, upon the Account of their own intrinſick Value and Merit, that Reſpect and Regard from me, and as, upon ſome Letters which paſſed betwixt them and me, before I Publiſhed my Demonſtration of the Chriſtian Religion many Years ago, I was ſure were Conſcientious and Learned Men, and were only Unfortunate in taking of Oaths, from which they could not depart, and for whom I am as certain, that the Worthy* Dr. Laughton, *Late Fellow of this College, had a very ſingular Regard too; The One of theſe Learned and Good Men is Dead, and the Other, who Survives him, is Reſpected and Eſteem'd by every one in this Univerſity, of what Denomination ſoever, who has not loſt all Senſe of Religion and Humanity. But my own Principles and Perſuaſions have been ever on the Side of the Oaths, which I have taken, and Conſequently on the Side of the Glorious and Happy Revolution, and againſt the Maxims of an Hereditary and Indefeiſible Right, as will be ſeen in a Latin Oration, Annexed to this Inquiry into Philoſophy, Spoken by* *me, when Bachelor of Arts of this College, and of which the Noble Perſon's Good Tutor, to whom theſe Papers are Inſcribed, was pleaſed to give thoſe Encomiums and Commendations, which, I am afraid, it did not deſerve.*

ONE of my firſt Lectures to my Pupils, after his Late Majeſty's *Happy Acceſſion to the Throne, was concerning the ſeveral Rights, by which Princes can be any ways ſuppoſed to Govern, which I told them muſt either be, by Conqueſt, or by Primogeniture, or by Election, or by a Recognition of the States of any Kingdom: That the firſt his Majeſty Renounced, as every Engliſh-Man Abhors, that he had a Legal and Juſt Claim upon the Second, ſince Primogeniture was reſtrained by the Laws to thoſe, who were Proteſtants, as likewiſe upon the Third, ſince the Voice of the People was on his Side, and alſo upon the Fourth, ſince the States in Parliament had evidently Recogniz'd him; That, as to ſtrict Primogeniture or Hereditary Right, Half of the Kings upon the Engliſh Throne, or more, ſince the Times of the Conqueror, had ſat there by Recognition of Parliament, who were not the Immediate Heirs to the Crown, and that the Conqueror himſelf, from whom they deriv'd, had ſet aſide* Edgar Atheling, *the True and Rightful Heir according to the Hereditary Scheme, as* Harold *before him had done; That on the other Hand the* Pretender *to the Imperial Crown of theſe Kingdoms had not one of theſe Rights; His Primogeniture was not only Diſputed, but there were great Reaſons to Think, that in Fact he was not a Legitimate Prince, nor had he the Voice of the People, or the Recognition of Parliament to ſupport his Pretenſions, and that it was Impoſſible for him to come in, any other Way, than by the firſt Title, Namely, that of Conqueſt; Which, as it was Odious in it's ſelf, muſt be alſo Maintain'd and Aſcertain'd thro' Seas of Blood, and at length by making all Engliſh Men, without Diſtinction, a Prey to Foreign Troops, and Foreign Maſters, either* Germans, Ruſſians, French, *or* Spaniards, *to the Total Ruin and Subverſion of our Religion, our Laws, and our Liberties.*

IN the Buſineſs of my Profeſſion, as a Clergy-Man, I have likewiſe taken all Occaſions, both at the Univerſity-Church, and in thoſe of the Pariſhes, where I am, or have been, Miniſter, to ſhew the Happineſs, We enjoy under his Late Majeſty's Excellent Adminiſtration, when the Times were Proper for ſuch Diſcourſes, as upon his Late Majeſty's Happy Acceſſion to the Throne; Nor have I been wanting in this College, as Dean, and Fellow of it, upon ſuch Publick Solemnities to Mark and Diſtinguiſh them by Appointing thoſe Orders and Rules to be Obſerved, which ſhould Expreſs a Becoming and Decent Feſtivity and Joy. But I Treſpaſs perhaps too much upon my Reader's Patience, and I rather, having this ſingle and only Opportunity in my Life to do it in ſo Publick a Manner, Recount this, to Declare to the World my unreſerv'd Sentiments in theſe Matters, under the Patronage of this Noble Perſon, than to Convince any one of my Loyalty and Affection to his Preſent, and to his Late moſt Excellent Majeſty, of which every Honeſt and Good Man, I dare ſay, has been always Satisfied.

PREFACE.

AS to my Principles of the Philoſophy of the Expanſive and Contractive Forces, or my Inquiry into the Modern Schemes and Syſtems of Nature, which I have humbly Preſumed to Addreſs to the Noble Perſon above Named, They are Principles, which I had Entertain'd concerning it very Early, and upon my firſt Application to the Studies of Philoſophy, and even before my Acquaintance with Sir Iſaac Newton's, which, in many Particulars, rather Juſtifies, than Contradicts, what I Propoſe: and when I was an Under-Graduate in this Univerſity, and could not ſee the Reaſon of the Abſtractions, which Mathematicians and Philoſophers made Uſe of in their ſeveral Sciences, I Applied my ſelf to the Late Reverend Dr. Laughton, who was then Eminent in thoſe Studies, was in Part my Tutor and my Friend, and who very kindly Endeavour'd to Inſtruct me, ſo far as he could, in thoſe Matters, but without giving me any farther Information, which I have ſince found, it was Impoſſible for him to do; Becauſe thoſe Abſtractions, which are at preſent Eſpous'd, are Wrong and Erroneous, and are the only Obſtruction and Hindrance to a farther Progreſs in Truth, and this kind of Knowledge, which I have Laboured to Remove, by Propoſing a Geometry and Philoſophy, which ſhall be Adequate to, and which ſhall reach, the whole Extent of Being.

I can only Say, that theſe Principles of the Expanſive and Contractive Forces have carried me much farther in the Explanations of Nature, and the Phenomenons of it, than I could at firſt have poſſibly Imagin'd; For I at firſt Thought, if I could give any tolerable Account of Matter, and what the Eſſence of it was, which all others Deſpaired of, I ſhould make a Notable Advance in that Science; And this was what I originally Intended; But Purſuing the ſame Principles, I perceiv'd they would give an Account not only of That, but of the various Properties and Affections of it, as Colour, Sound, Taſte, Smell, &c. Sir Iſaac Newton's Gravitation, and even of the Surprizing Effects in Chymiſtry, of the Vegetation of Plants, of the Conſtitution and Formation of the Parts of an Human Body, of the Reaſon of the Revolution of the Planets, of the Capacities and Powers of the Mind, and of the Union of the Material Syſteme with it; Problems, which all Philoſophers have hitherto Reſigned as not to be Solved, and which yet ſeem to be fairly Explained upon the ſame Principles of the Expanſive and Contractive Forces. My Reader may eaſily Suppoſe, that ſuch Contemplations, as theſe, did therefore Afford me Matter both of Pleaſure and Aſtoniſhment, and I do humbly beg Leave to Profeſs to the World, that I believe there is ſcarcely any Phenomenon in Nature, which may not be Accounted for from the ſame Principles.

AS to my Reaſonings upon theſe Subjects, I am not much Apprehenſive, that they are Inferiour to thoſe of the Philoſophers, whom it is my Misfortune not to Agree with; But Prejudice and Partiality and a Fondneſs for Great Names, without ever Inquiring into Things themſelves, are Hard and Obſtinate Buſineſſes to Encounter, which yet I would hope might be Diminiſhed, if Men would but Conſider that ſeveral Opinions and Syſtems of Philoſophy were Patronized and Defended in the Free-State of Athens, without any great Re-

proach to any Sect of them, and why may not the ſame Liberty be Indulged to the Free-State of Great-Brittain?

THE *Famous and Celebrated Univerſity of* Oxford *at this Time adheres to the* Ariſtotelian *Scheme, and our own of* Cambridge, *which is no leſs Renowned for its Studies and its Learning, and the Great Men it has Produced, ſeems to be too much Addicted to the* Carteſian, *or, which is much the ſame as to the Principles of a Similar and Homogeneous Matter, to the* Newtonian; *On the Contrary, as* Ariſtotle *Affirmed Four Principles,* Des-Cartes *Three, and Sir* Iſaac Newton *One, which is that of Gravitation or Attraction, I beg the Favour, under the Patronage and Protection of the Noble Perſon I have Mentioned, to Intrude my ſelf amongſt theſe Philoſophers, and to Declare there are neither More nor Leſs than Two; Namely, the Expanſive and Contractive Force. I cannot but here Acquaint the World, that the Preſent Philoſophers Derive all their Notions of Nature from* Italy *and* Galileus, *or from* Des-Cartes *and* France, *Excepting what* Kepler *a* German *has done in Reſpect of thoſe Sciences, and from whom Sir* Iſaac Newton *is ſaid to have taken his Principle of Gravitation, and who is Eſteem'd to have been the moſt Learned and Sagacious Man of his Age; But in all other Reſpects, our Philoſophy, as it is now Received and Embraced, is the Product of Popiſh Countries, Imported to us from* Italy *and* France, *and I will leave the World to Judge, whether Superſtition and Foppery in Religion in any Nation, will not make an Impreſſion of Atheiſm or Deiſm upon the Philoſophy of it, as it moſt certainly has done.*

ALL *therefore, which I Deſign and Intend, is to Propoſe a Philoſophy, which is truly* Engliſh, *a* Cantabrigian, *and a* Clarenſian *one, as it was Born and Educated and Studied in thoſe Places, and which it is not Impoſſible may be as Juſt in its Reaſonings, and as Good in its Religion, as That which is brought over to us from Countries, which abound either in Superſtition or in Atheiſm; And as my Name is not much Worſe in the Letters, which belong to it, than thoſe of* Galileus, *or* Des-Cartes, *and for Reaſons Alledged at the End of this Philoſophy, by which it is Evident, there are only Four Ways of Explaining Nature, One of which I have Taken, and no One elſe has done, I ſhall Venture to call the* GREENIAN.

THE *Original Occaſion of my Purſuing theſe Inquiries with that Vehemence and Application, which I have Uſed, was upon the Account of my Dear and Good Pupils, whom I Love, and whom, I thought, I was to Inform, as well as I could, and not to Indulge them in Errors, which I could not Subſcribe to; and which, if they are ſuch, as Philoſophy is the Parent of Phyſick, muſt have coſt Millions of Lives in the Practice of it, upon Corpuſcularian or Atomical Principles, or, which is the ſame, upon thoſe of a Similar and Homogeneous Matter; Beſides, the Impreſſion ſuch Notions have made upon Chriſtianity it ſelf, to its great Prejudice, as may be ſeen in the following Sheets, will Sufficiently Juſtify me in the Oppoſing of them.*

PREFACE.

IF there are any Miſtakes in this Scheme of Philoſophy, as Perhaps there may be many, for it is a moſt difficult Thing to Explain, what Exiſtence or Being is, I may yet Say, that I have uſed all the Integrity, Diligence and Capacity, which it is Poſſible for me to do, and that it is much Eaſier to Underſtand an Hundred Volumes in the Greek *or* Latin *Authors, than That ſingle One of Nature. I muſt however beg Leave to Plead in Excuſe to the World, if I am Miſtaken in the Main, as I believe, and am pretty well Aſſured, I am not, That this Inquiry, as Large as it is, has been amidſt ſeveral other Studies, Buſineſſes and Employs, which have had a Relation to the College, to my Pupils, or my Pariſhes, all of whom I moſt Exceedingly Love, Value, and Eſteem; And, if it had not been upon their Accounts, and for the Charge and Expenſe of Printing, and Creating too great a Fatigue and Trouble to my Reader, I could have Extended theſe Inquiries to five Times the Number of Sheets, which I here Preſent to the World, and which any One will See and Perceive upon a Curſory Peruſal of them only.*

I have one farther Apology to make to the World, that many of theſe Papers were Written ſeveral Years ago, even before the Printing of my laſt Book of Philoſophy in 1712, *to which the Noble Perſon, I have ſo often Referred to, gave me the kind Encouragement of his Subſcription, and which has not been Confuted, nor can be, by any of our Modern Reaſoners, however Great their Names may be, and however High their Reputations may Stand, in the Philoſophick or Mathematick World. On the Contrary, the Celebrated Sir* Iſaac Newton, *in ſome Meaſure, falls into my Notions, and now Confeſſes a Plenum, or ſomething like it, who had in the firſt Edition of his Principles Propoſed to Demonſtrate, that there muſt of Neceſſity be a Vacuum, againſt which I Argued in the ſaid Book, and of which I did my ſelf the Honour to make a Preſent to him upon the firſt Publication of it. But I ſhall Tire my Reader with theſe Preliminary Explanations, and would only Humbly beg the Favour of him at his Leiſure-Hours, that he will Pleaſe to Inquire with me, whether the Philoſophers are True or not, in their Solutions of the ſeveral Problems in Nature, which, I think, I may punctually Affirm, they are not; and I am Satisfied, that whenever any One of Common Sagacity and Penetration will take that Province upon himſelf, he will find all the Reaſons in the World to enter into the ſame Sentiments; That is, if he firſt Reads thoſe Authors in Philoſophy, whom I Quote, and then Sits down to Conſider of them; I only ſhall Add, that I Eſteem and Look upon this, together with my Philoſophy of* 1712, *as my Second Demonſtration of the Chriſtian Religion, by ſhewing the Fallacies of thoſe Reaſonings in a Philoſophy, which ſeems to Oppoſe it, or to have very little Regard for it; My farther Demonſtrations of the ſame Excellent Religion will be, with his Allowance and Permiſſion, Addreſſed to the Good* Marqueſs of Blandford, *for whom, during his Reſidence here, as I Received from him the moſt Signal Kindneſſes and Condeſcenſions, and as his Piety, Charity, Humility, and Goodneſs, were beyond Example, I cannot but always have the higheſt Eſteem and Veneration; Which Demonſtrations of the Chriſtian Religion Lie Written by me, and are ready, in ſome ſhort Time, if he will Pleaſe to Allow them that Honour, for his Lordſhip's Patronage.*

THE

PRINCIPLES

OF THE

PHILOSOPHY

OF THE

EXPANSIVE and CONTRACTIVE FORCES.

Book I.

CONCERNING the Principles of the Mechanical Philoſophy of *Galileus*, *Chriſtian Hugens*, Sir *Iſaac Newton*, and Dr. *Keill*.

Book II.

Concerning Thoſe of the Phyſical Aſtronomy of *Kepler*, Sir *Iſaac Newton*, and Dr. *Gregory*.

Book III.

Concerning the Principles of Anatomy, Chymiſtry, Pneumaticks, and Hydroſtaticks, of Dr. *Gibſon*, Dr. *Keill*, Dr. *Drake*, *Tauvry*, *Blancard*, and *Alphonſus Borellus*; Of *Lemery*, Mr. *Boyle*, and Dr. *Freind*; and of Dr. *Wallis*, Dr. *Halley*, and Others.

Book IV.

Concerning Thoſe of the Opticks, Dioptricks, and Catoptricks, of *Des-Cartes*, *Rohault*, *Molyneux*, Dr. *Gregory*, and *Hugens*.

Book V.

Concerning the Principles of the Metaphyſicks and Logicks, or of the Eſſay upon Human Underſtanding, of Mr. *Locke*.

Book VI.

Concerning Thoſe of the Ethicks, or the Natural Religion, of the ſaid Eſſay, and of *Des-Cartes*'s Meditations, of Dr. *Clarke*, and Mr. *Wollaſton*.

Book VII.

Concerning the Principles of Mathematicks, Fluxions, the Infinite Series, and Algebra.

In all which *Sciences*, Compared with the ſeveral Demonſtrations of the *Chriſtian Religion*, is Shewn,

That the Evidences for *Revelation* are Exceedingly Superior to Thoſe of *Philoſophy and Reaſon*, Being, Together with the *Inquiry into the Principles* of *Natural Philoſophy*, Publiſhed *Anno Domini* 1712, the Second Demonſtration of the *Truth* of the *Chriſtian Religion*, The Firſt being Publiſhed *Anno Domini* 1711.

THE

THE

CONTENTS.

BOOK I.

Concerning the PRINCIPLES of the MECHANICAL PHILOSOPHY.

CHAP. I. *CONCERNING Similar Matter, a Vacuum, and the New Theory of Light and Colours, and of Sounds, with a Solution of the Rainbow.*

CHAP. II. *Concerning the Principles of the Mechanical Philoſophy, and the Matter and Motion Aſſerted in it; As alſo of Space, Place, Time or Duration, and Celerity.*

CHAP. III. *Concerning the Principal Theorems of the Mechanical Philoſophy, with a Propoſal of a New Syſteme of Mechanicks.*

CHAP. IV. *Concerning the Five Mechanical Powers, and the Demonſtrations of them.*

CHAP. V. *Concerning the Expanſive and Contractive Forces, Acting in a Center of Detention, or in any Diſtances, or Removals, from it.*

CHAP. VI. *Concerning the Mutual Concourſe of Bodies Hard, Soft, or Elaſtick.*

CHAP. VII. *Concerning the Deſcent of Heavy Bodies in Inclin'd Planes, and the Oſcillation of Pendulums.*

BOOK II.

Concerning the Principles of the Phyſical Aſtronomy.

CHAP. I. *Concerning the Laws of Nature and Motion.*

CHAP. II. *Concerning the Mutual Concourſe of Bodies and the Laws Relating thereto, as alſo of the Compoſition of Forces.*

CHAP. III. *Concerning the Method of Naſcent and Evaneſcent Reaſons.*

CHAP. IV. *Concerning the Fundamental Propoſitions of this Philoſophy, and the Application of Them to the Solving the Revolutions of the Planets.*

CHAP. V. *Concerning the Theory Propoſed by this Philoſophy for the Solution of the Errors and Irregularities of the Planets.*

CHAP. VI. *Concerning thoſe Propoſitions, which Relate to the Particular Forces, by which the Planets are Retain'd in their Orbits.*

BOOK. III.

Concerning the chief Properties of Matter, as alſo Concerning the Principles of Chymiſtry, Anatomy, Pneumaticks and Hydroſtaticks.

CHAP. I. *Concerning the Chief Properties of Material Beings.*

CHAP. II. *Concerning the Principal Phænomenons Obſervable in Chymiſtry.*

CHAP. III. *Concerning the Phænomenons in Anatomy, and Firſt of the Common and Proper Containing Parts of the Abdomen, the Cuticula, the Reticulum Mucoſum, the Cutis, the Membrana Adipoſa and Carnoſa, the Communis Membrana Muſculorum, the Peritonæum and Omentum.*

The CONTENTS.

CHAP. IV. *Concerning the OEſophagus or Gullet, the Ventricle or Stomach, and the Inteſtines or Guts, and of the Mouth and Palate.*
CHAP. V. *Concerning the Liver, the Gall-Bladder, the Spleen, and the Pancreas.*
CHAP. VI. *Concerning the Meſentery, the Receptacle of the Chyle, the Thoracick Duct, and the Via Lactea, or the Paſſage of the Chyle into the Blood.*
CHAP. VII. *Concerning the Thorax, Diaphragm, Pleura, and Mediaſtinum.*
CHAP. VIII. *Concerning the Heart, and it's Pericardium, the Aorta and Cava, the Arteria and Vena Pulmonaris, and Circulation of the Blood.*
CHAP. IX. *Concerning the Expanſive and Contractive Forces.*
CHAP. X. *Concerning Pneumaticks and Hydroſtaticks, and a Real Space or Extenſion, or of Air and Æther, and the ſeveral Kinds of Experiments made in them.*

BOOK IV.

Concerning Opticks, Dioptricks, and Catoptricks.

CHAP. I. *Concerning the Doctrine of Reflection, as Propoſed by* Deſcartes *from Impulſe and Reſiſtence.*
CHAP. II. *Concerning Sir* Iſaac Newton's *Hypotheſis of Reflection from Impulſe and Attraction.*
CHAP. III. *Concerning Dr.* Wallis's *Hypotheſis of Reflection from Impulſe and Elaſticity.*
CHAP. IV. *Concerning the ſeveral Hypotheſes of Refraction.*
CHAP. V. *Concerning the Fundamental Principles of Opticks.*
CHAP. VI. *Concerning the Propoſitions in Opticks, which Relate to Glaſſes, which are either double Convex, or Plano-Convex Ones.*
CHAP. VII. *Concerning the Reſpective and Vertual Focus's of Glaſſes.*
CHAP. VIII. *Concerning Meniſcus-Glaſſes, and the Propoſitions thereto Belonging.*
CHAP. IX. *Concerning Simple or Plain Viſion.*
CHAP. X. *Concerning Viſion, as Performed thro' Single Glaſſes, Plane or Convex, which are Interpoſed betwixt the Object and the Eye.*
CHAP. XI. *Concerning other Propoſitions, which Relate to Convex Glaſſes, Interpos'd betwixt the Object and the Eye.*
CHAP. XII. *Concerning the Properties of Concave Glaſſes, Placed betwixt the Object and the Eye.*
CHAP. XIII. *Concerning the Propoſitions, which Relate to Teleſcopes and Microſcopes.*
CHAP. XIV. *Concerning the Propoſitions Relating to Catoptricks.*

BOOK V.

Concerning the Metaphyſicks and Logicks, or the Syſteme of Ideas of Mr. *Locke*.

CHAP. I. *Concerning the Deſign and Intention of the Eſſay on Human Underſtanding.*
CHAP. II. *Concerning no Innate Ideas, and the Mind's being a* Raſa Tabula.
CHAP. III. *Concerning Simple Ideas.*
CHAP. IV. *Concerning Perception.*
CHAP. V. *Concerning Retention, and of Diſcerning, Comparing, and Compounding, our Ideas.*
CHAP. VI. *Of Complex Ideas, and Firſt, of Simple Modes of Space and Duration.*
CHAP. VII. *Concerning the Complex Ideas of Number, Infinity, Motion, Colour, Taſte, and Smell.*
CHAP. VIII. *Of the Modes of Thinking; Of Pleaſure and Pain; Of Power; Of Mixed Modes; Of our Complex Ideas of Subſtances; Of Collective Ideas of Subſtances; Of Relation; Of Cauſe and Effect; Of Identity and Diverſity; Of Other Relations; Of Clear and Obſcure, Diſtinct and Confuſed Ideas; Of Real and Fantaſtick Ideas; Of Ideas Adequate or Inadequate; Of True and Falſe Ideas; and Of the Aſſociation of Ideas.*

CHAP. IX.

The CONTENTS.

CHAP. IX. *Of Words or Language in General; Of the Signification of Words; Of General Terms; Of the Names of Simple Ideas; Of the Names of Mixed Modes and Relations; Of the Names of Subſtances; Of Particles; Of Abſtract and Concrete Terms; Of the Imperfection of Words; Of the Abuſe of Words; Of the Remedies of the Foregoing Imperfections and Abuſes.*

CHAP. X. *Of Knowledge in General; Of the Degrees of our Knowledge; Of the Extent of Human Knowledge; Of the Reality of our Knowledge; Of Truth in General; Of Univerſal Propoſitions, their Truth and Certainty; Of Maxims; Of Trifling Propoſitions; Of our Knowledge of Exiſtence; Of our Knowledge of the Exiſtence of a God; Of our Knowledge of the Exiſtence of other Things; Of the Improvement of our Knowledge; Some Farther Conſiderations Concerning Knowledge; Of Judgment; Of Probability; Of the Degrees of Aſſent; Of Reaſon; Of Faith and Reaſon, and their Diſtinct Provinces; Of Enthuſiaſm; Of Wrong Aſſent, or Error; Of the Diviſion of the Sciences.*

BOOK VI.

Concerning the Ethicks, or Natural Religion, of *Des-Cartes*'s Meditations, Mr. *Locke*'s Eſſay, of Dr. *Clarke*, and Mr. *Wollaſton*.

CHAP. I. *Concerning the Little Importance of Natural Religion, after the Revelation of the Chriſtian.*

CHAP. II. *Concerning the Evidences from Self-Information.*

CHAP. III. *Concerning the Evidences of Teſtimony, or Thoſe Informations, we Receive from Others.*

CHAP. IV. *Concerning the Being of a God, and the Demonſtration of it, from* Des-Cartes's *Connexion of Ideas.*

CHAP. V. *Concerning Mr.* Locke's *Demonſtration of the Being of a God.*

CHAP. VI. *Concerning the Moral Relations of this Philoſophy.*

CHAP. VII. *Concerning Ideas from Senſation and Reflection, and that there are Ideas in the Mind Perfectly Immaterial.*

CHAP. VIII. *Concerning Identity and Diverſity.*

CHAP. IX. *Concerning Enthuſiaſm.*

BOOK VII.

Concerning Algebra.

CHAP. I. *Concerning Notation, Addition, Subſtraction, Multiplication, Diviſion, and Extraction of the Roots.*

CHAP. II. *Of the Reduction of Fractions and Radicals to the Leaſt Terms, or to the Same Denomination, as alſo of Radicals to more Simple Radicals by the Extraction of the Roots; And likewiſe, Of the Form of Equations, the Diſpoſition of Them, and the Extermination of the Unknown Quantities out of Them.*

CHAP. III. *Concerning the Solution of Problems, and Reducing them to Equations.*

CHAP. IV. *Of Affected Quadratick Equations, and the ſeveral Forms of Them.*

CHAP. V. *Of the ſeveral Ways of Managing Equations of Higher Powers, and Extracting the Roots of them, by* Stevin, Harriot, Vieta, Kerſey, Cardan, *or* Scipio Ferreus, *as alſo by* Des-Cartes, *Sir* Iſaac Newton, *Dr.* Halley, *and Mr.* Raphſon.

CHAP. VI. *Which is Miſcellaneous, Namely, Concerning the Infinite Series, the Square of the Circle, the Inveſtigation of the Longitude; Of Thunder and Lightning; Of the Rainbow; Of the Vegetable Staticks; A Juſt Ridicule of the Corpuſcularian Scheme, or That of Similar or Homogeneous Matter; Concluſion, by Shewing, how many Hypotheſes there are, by which it is Poſſible for Nature to be Explained by Philoſophers.*

The CONTENTS.

MISCELLANEA QUÆDAM PHILOSOPHICA.

I. *Diſſertatio de Nova Infinitarum Serierum Doctrina, prout a Newtono Aliiſque Affirmantur.*

II. *De Alia Circuli Quadratura, præter Eam, quam in Geometria Solidorum Attulimus; Item, de Problemate Deliaco, ſive Cubi Duplicatione.*

III. *De Conicis Sectionibus Clariſſimi Viri Jacobi Milneſii.*

IV. *Imperfecta Quædam de Longitudine, nec niſi Solummodo Inchoata.*

V. *De Philoſophorum Argumentis ad Vacuum Probandum, deque eorum Calumnia & Infirmitate.*

VI. *De Motu, Gravitatione, & Cohæſione Materiæ, Eaque ex Immediata Dei Actione Profluere.*

VII. *De Rationibus Geometricis, Eaſque Animo perinde Competere, qua Percipienti, ac Materiæ, qua Extenſæ.*

VIII. *Medicinæ Collaudatio, ſive Oratio Habita ante primam Amiciſſimi mihi Viri* Thomæ Hewett A. M. *Diſputationem pro Gradu Doctoratus in Medicina,* Jun. 28. 1707.

IX. *Collaudatio Juris-Civilis, ſive Oratio habita in Scholis Baccalaureorum Cantabrigiæ* Jun. 25. 1707. *cum* Thomas Paske A. M. *Vir mihi Amiciſſimus diſputavit primo pro Gradu Doctoratus in Jure-Civili.*

X. *Gratulatio ad Epiſcopum Elienſem* Johannem Moore, S. T. P. *Patronum quondam Chariſſimi Amici* Caroli Morgan A. M. *Magiſtri hujus Aulæ Optimi, & quadantenus Patronum Meum.*

XI. *Oratio Panegyrica in Divum Gulielmum, apud Nonas Novembris* 1701, *ad Prænobilem Virum, mihi autem & Amico meo Humaniſſimum Patronum* Thomam Holles, *Ducem Præcellentiſſimum de Novo-Caſtello.*

THE PRINCIPLES OF THE PHILOSOPHY OF THE EXPANSIVE and CONTRACTIVE FORCES.

BOOK I.

Concerning the Principles of the MECHANICAL PHILOSOPHY.

INTRODUCTION.

BOOK I.

CHAP. I.

Concerning Similar Matter, a Vacuum, and the New Theory of Light, and Colours, and of Sounds, with a Solution of the Rainbow.

The Difference betwixt us, and the preſent Philoſophers.

§. 1. BEFORE we Proceed to an Inquiry into, and an Explanation of the *Principles* of the *Mechanical Philoſophy*, and the *Phyſical Aſtronomy*, it will be neceſſary to clear our Way to it, by Conſidering what has been alledg'd againſt us in Relation to our *Principles of Natural Philoſophy*; in which our Principal Affirmations were, that there is no ſuch Thing as a Vacuum in Nature, that Matter is not Similar and Homogeneous, but that Light is ſo, that the Qualities or Properties of Matter, which occaſion the Senſations in us of Taſting, Smelling, Feeling, Hearing, and Seeing, are not deriv'd from different Modifications of the ſame Homogeneous Matter, nor from any Figures of the Corpuſcles of it, or Actions in it; but from certain innate Forces which are Inherent therein, which Forces we propos'd to Explain: On the contrary the preſent Philoſophy informs us, that there is a Vacuum, that Matter is Similar and Homogeneous, but that Light is not, that the Properties of Matter, by which one Portion of it is diſtinguiſh'd from Another, are owing to the particular Figure of it's Parts, and to it's Variety of Pores, and to the Motions of ſuch Parts one amongſt another.

Concerning a Vacuum, and how that Controverſy ſtands at Preſent.

Principles of Natural Philoſophy, Chap. 5. §. 43. Part. 1.

Sir Iſ. Newt. Princip. Prop. 6. Corol. 3. Lib. 3. Edit. 1. & 2.

§. 2. As to a Vacuum, we ſaid, that the Proofs of it turn'd upon a Suppoſition, that all Matter was Homogeneous, which was the very Thing in Queſtion, for if all Matter was alike, and the World was full of it, it was own'd, there could be no Specifick Gravity, but that all Matter was alike, was diſputed and in Terms deny'd, and this Subject we proſecuted thro' our whole fifth Chapter of the Principles of Natural Philoſophy, and §. 43. we ſhew'd the Inconcluſiveneſs of the Argument drawn from Specifick Gravity to evince a Vacuum: On the contrary the preſent Philoſophy in it's firſt Edition had affirm'd from thence *the Neceſſity of a Vacuum*, which whether convinc'd by what I had offer'd in Contradiction to that Demonſtration, or upon a farther Canvaſſing and Conſidering the Matter, it, in the ſecond Edition, alter'd to this Aſſertion, that, *all Spaces were not equally full*, if by that is meant, that ſome Spaces are not full, but on the Contrary are void of all Matter, 'tis the ſame as the former Propoſition, that *there is a Vacuum*, and all the Advantage there is in the Change, is, that it is more doubtfully and ambiguouſly, and therefore more oraculouſly Expreſs'd; if by it is meant, that *all Spaces are full of Matter, but not equally ſo*, the firſt Proſelyte we have had to our Reaſoning and Arguments, is the Perſon, whoſe Reaſoning and Arguments we oppos'd, ſince that is what we maintain, that there is a Plenum, but that Matter being Various and Diſſimilar, Spaces are not full of the ſame Matter, but are repleniſh'd with different Sorts and

Kinds of it, and therefore are not *equally full*; but this is an Honour ſo mean a Perſon, as I, cannot expect.

Sir Iſ. Newt. Optical Queries 18, 19, 20, 21, 22.

That this Philoſophy yet has ſome Inclinations to embrace this Opinion which I have defended, is manifeſt likewiſe from a new Edition of it's Light and Colours, and the Optical Queries annext to it, where an Æthereal Medium is introduc'd, which may have little or no Reſiſtance to the Motions of the Planets and Comets, which may be the Occaſion of the Refractions and Reflections of Light, and by whoſe Vibrations Light may communicate Heat to Bodies, and be put into Fits of eaſy Reflection, and eaſy Tranſmiſſion; and by whoſe Elaſticity Gravity is thought to be accounted for: Theſe are all Notions which tend to the Confirming of what I originally advanc'd, that there is an Æthereal Plenum, and which the Great and Divine Dr. *Barrow* has long ſince patroniz'd and aſſerted, and the Learned and Judicious Dr. *Pearſon* adopted into his own Perſuaſions and Opinions.

Sir Iſ. Newt. Optical Query 28.

But notwithſtanding theſe Conceſſions, this Philoſophy ſtill relapſes into it's old Doctrine of a Vacuum, and a Similar Matter in the *28th* Query, and eſteems all Hypotheſes to be Erroneous in which Light is ſuppos'd to conſiſt in Preſſion or Motion propagated thro' a Fluid Medium, and all that is argu'd in that Query concerning the Rarity and Denſity of a Medium is upon the Suppoſition, that there is no other Rarity or Denſity, but what proceeds from the Minuteneſs or Groſsneſs of the Parts of the ſame Similar Matter, and the leſs or greater Number of them in the ſame Space, from whence it concludes, that a Plenum or a Denſe Fluid can be of no uſe for explaining the Phænomena of Nature, and therefore may be juſtly rejected; for the doing of which, it is ſaid, we have the Authority of the oldeſt and moſt eminent Philoſophers of *Greece* and *Phœnicia*, who made a Vacuum and Atoms, and the Gravity of Atoms, the firſt Principles of their Philoſophy: It is farther here told us, that the main Buſineſs of Natural Philoſophy is to argue from Phænomena without feigning Hypotheſes; and to deduce Cauſes from Effects, till we come to the firſt Cauſe, which certainly is not Mechanical, and not only to unfold the Mechaniſm of the World, but chiefly to reſolve theſe and ſuch like Queſtions; What is there in Places *Empty of Matter*, and whence is it that the Sun and Planets gravitate towards one another *without denſe Matter* between them? Whence is it that Nature doth nothing in vain? And whence ariſes all that Order and Beauty which we ſee in the World? To what end are Comets, and whence is it that Planets move all one and the ſame way in Orbs Concentrick, while Comets move all manner of ways in Orbs very Excentrick; and what hinders the fixt Stars from falling upon one another, *&c.* for we ſhall take notice of no more Queſtions here, becauſe the following relate to the Animal and Intelligent World, which do's not come under our preſent Conſideration.

A Vacuum muſt be defended by this Philoſophy, or elſe it muſt Renounce it's Principles.

§. 3. **From** whence it is evident, that this Philoſophy ſcarcely knows what to aſſert, ſometimes it ſeems to think there is a Plenum, but that *all Spaces are not equally full*, that there is an Æthereal Medium ſpread and diffus'd thro' the whole Solar Syſteme, which may occaſion the Refractions and Reflections of Light, and the Fits of eaſy Reflection and eaſy Tranſmiſſion, by whoſe Vibrations Light may communicate Heat to Bodies, and Gravity be poſſibly ſolv'd by it's Elaſticity; at other Times it is ſaid, a Plenum can be of no uſe for explaining the Phænomena of Nature, and is therefore to be rejected, and for the doing of which we have the Authority of the ancienteſt and beſt Philoſophers of *Greece* and *Phœnicia*.

To clear up this Matter a little therefore to the preſent Philoſophy, we muſt take the Liberty to inform it, that however glad we might be to have ſo great an Authority to juſtify our Reaſonings upon this Subject, it cannot come into the acknowledgement of a Plenum, without Diſcarding and Diſavowing it's own Principles, and therefore it might as well have retain'd it's Aſſertion of the *Neceſſity of a Vacuum*, according to the firſt Edition of them, as alter'd it to another, that *all Spaces are not equally full*, which is done in the ſecond; for tho' one who maintains a Diſſimilar and Heterogeneous Matter in it's own Nature, may agreeably and conſiſtently with ſuch a Notion affirm a Plenum of a thin and ſubtle Æther, which is as much and as ſubſtantially Matter as the groſeſt we can Name, yet the Caſe is not the ſame with thoſe, who define Matter to be one Similar, Paſſive, Solid, Extended and Invariable Thing, ſince if Spaces are full of ſuch a Matter, it is evident it will be all one, as if it was full of the groſseſt, for Inſtance of Lead or Gold, ſeeing there is no Difference in Matter, as it is ſuch, and conſequently it is truly and juſtly concluded, that there would be no Specifick Gravity, and Bodies would no more deſcend in Air, than they do in Gold.

The Objections againſt a Vacuum and a Similar Matter farther conſider'd and enforc't, with a Deſcription of this Similar Matter.

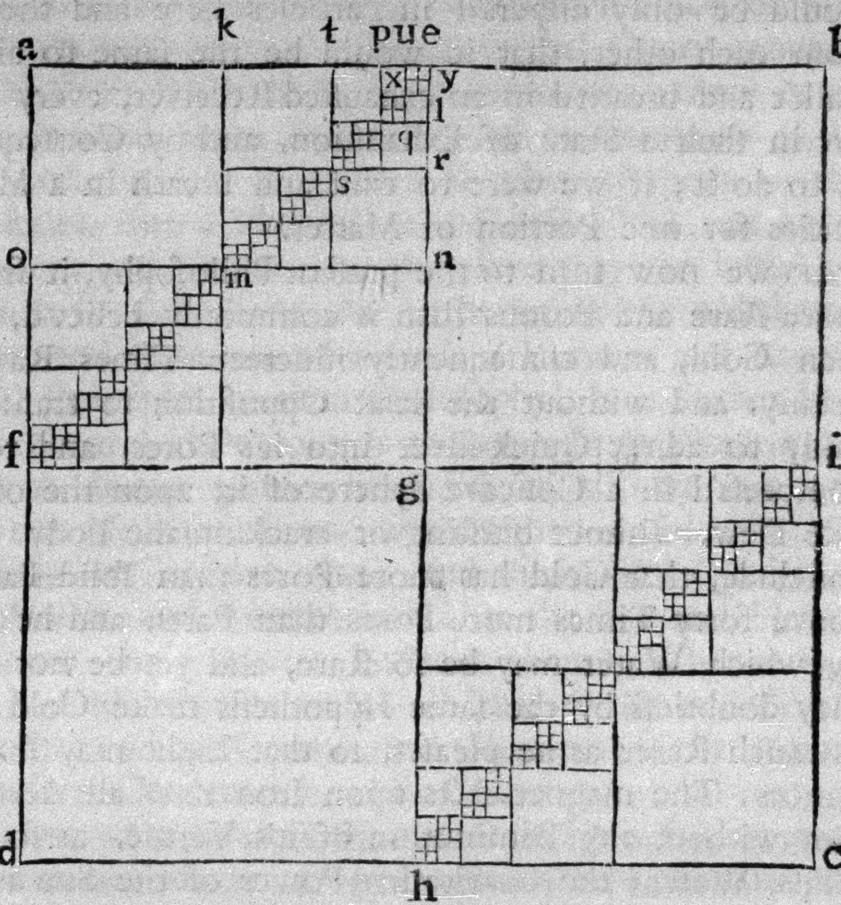
§. 4. Since then a Vacuum is what the preſent Philoſophy muſt defend, however it may appear to moderate and qualify it's Aſſertions concerning it; we ſhall firſt conſider ſome farther Arguments alledg'd for the Proof of it, which we did not particularly inquire into, tho' they were in General anſwer'd in our *Principles of Natural Philoſophy*, and afterwards examine into the pretended Authority of the Philoſophers of *Greece* and *Phœnicia* for the rejecting a Plenum, and eſpouſing a Vacuum, and it's Atoms and the Gravity of them.

As to the firſt, one principal Objection againſt a Vacuum and a Similar Matter, for they muſt ſtand and fall together, is, that in the infinite Rarity of the Air, according to this Doctrine, where there is nothing but Similar Matter or Pores and Vacuities, there would be ſo much Vacuum, and ſo little Matter in Proportion, which would be only diſpers'd in Particles here and there at very conſiderable Diſtances from each other, that it would be the ſame to all Intents and Purpoſes, as if we walk't and breath'd in an exhauſted Receiver, every one knows, that no Animals can live in ſuch a State of Exhauſtion, and by Conſequence it wou'd be impoſſible for us to do it; if we were to exiſt and breath in a Medium, which has a thouſand Vacuities for one Portion of Matter.

Sir Iſ. Newt. Opticks Prop. 8. Part 3. Book 2.

If we now turn to the preſent Philoſophy, it frankly owns, that Bodies are much more Rare and Porous than is commonly believ'd, Water is nineteen Times lighter than Gold, and conſequently nineteen Times Rarer, and Gold is ſo rare, as very readily, and without the leaſt Oppoſition to tranſmit the magnetick Effluvia, and eaſily to admit Quick-ſilver into it's Pores, and to let Water paſs thro' it, when compreſs'd in a Concave Sphere of it, upon the outſide of which it ſtands in Drops like Dew, without burſting or cracking the Body of Gold, from all which we may conclude, that Gold has more Pores than ſolid Parts, and therefore that Water has above forty Times more Pores than Parts, and he that ſhall find out an Hypotheſis by which Water may be ſo Rare, and yet be not capable of Compreſſion by Force, may doubtleſs by the ſame Hypotheſis make Gold and Water, and all other Bodies as much Rarer as he pleaſes, ſo that Light may find a paſſage thro' tranſparent Subſtances: The magnet Acts upon Iron thro' all denſe Bodies, not magnetick nor red Hot without any Diminution of it's Vertue, as for inſtance, thro' Gold, Silver, Lead, Glaſs, Water; the Gravitating Power of the Sun is tranſmitted thro' the vaſt Bodies of the Planets without any Diminution, ſo as to act upon all their Parts to their very Centers with the ſame Force, and according to the ſame Laws, as if the Part upon which it Acts were not ſurrounded with the Body of the Planet; the Rays of Light, whether they be very ſmall Bodies projected, or only Motion or Force propagated, are mov'd in Right Lines, and whenever a Ray of Light is by any obſtacle turn'd out of it's Rectilinear Way, it will never return into the ſame Rectilinear Way, unleſs perhaps by very great Accident, and yet Light is tranſmitted thro' Pellucid ſolid Bodies in Right Lines to very great Diſtances. How Bodies can have a ſufficient Quantity of Pores for producing theſe Effects is very difficult to conceive, but perhaps not altogether Impoſſible: For the Colours of Bodies ariſe from the Magnitudes of the Particles, which reflect them, as was explain'd above; now if we conceive theſe Particles of Bodies to be ſo diſpos'd amongſt themſelves, that the Intervals or empty Spaces between them may be equal in Magnitude to them All, and that theſe Particles may be compos'd of other Particles much ſmaller, which have as much empty Space between them, as Equals all the Magnitudes of theſe ſmaller Particles, and that in like manner, theſe ſmaller Particles are again compos'd of Others much ſmaller, all which together are equal to all the Pores or empty Spaces between them, and ſo on Perpetually till you come to the ſolid Particles, ſuch as have no Pores or empty Spaces within them. [Why if ſo, what then? truly nothing at all, for this Philoſophy here, as in what follows, is ſo Wiſe as to leave us without a Concluſion:] And if in any groſs Body, there be for Inſtance, three ſuch Degrees of Particles, the leaſt of which are Solid, this Body will have ſeven Times more Pores than ſolid Parts: But if there be four ſuch Degrees of Particles, the leaſt of which are Solid, the Body will have fifteen Times more Pores than ſolid Parts; if there be five Degrees, the Body will have one and thirty Times more Pores than ſolid Parts; if ſix Degrees, the Body will have ſixty and three Times more Pores than ſolid Parts, and ſo on perpetually; and there are other ways of conceiving how Bodies may be exceeding Porous, but what is really their inward Frame is not yet known to us.

THUS in Reſpect of the Calculation above, let *abcd* repreſent the Square Section of a Cubical Particle of Matter, divided firſt into four Square Areolæ, and let one be Matter, and the other Vacuity alternately; Then let *aegf* be divided into four other Square Areolæ, the one Matter, and the other Vacuity alternately, and let the ſame be done by the other Particle of Matter in the firſt Diviſion: Afterwards let *kemn* be divided into four other Square Areolæ, the one Matter, and the other Vacuity alternately; and let the ſame be done by every of the Particles of Matter in the ſecond Diviſion; The Matter in this third Diviſion will be to the Vacuities or Pores as 1 to 7, becauſe the Matter in *kemn* will be to the Vacuity, as 1, Matter, to 1, Vacuity; and *akmo* will be 2, Vacuity; and therefore the Matter in *kemn* will be to the Vacuity in *kemn*, and *akmo* as 1, Matter, to 3, Vacuity; and the ſame may be ſaid of the reſt of the Matter in *aegf* to it's Vacuity, that it will be, as 1, Matter, to 3, Vacuity, which conſiſts therefore of four Parts, but *egbi* will conſiſt likewiſe of four Parts, all of which will be Vacuity, and conſequently the Portion of Matter in the Space *abif*, will be to the Vacuity in the ſame Space, as 1 to 7, and the ſame may be ſaid of all the other Portions of Matter and Vacuity in the Space *abcd*: Let now the leaſt Part of Matter in *kemn*, viz. *erst* be divided into four other Square Areolæ, the one Matter, the other Vacuity; the leaſt Part of Matter therefore in *kemn* will be divided into Two, one of which will be Matter, and the other Vacuity, and the leaſt Part of Vacuity will likewiſe conſiſt of two Parts, and the Matter in the leaſt Particle of it in *kemn* will be to Vacuity as 1 to 3, and the ſame may be ſaid of all the Particles of Matter and Vacuity in *kemn*, which conſequently will conſiſt of four Parts, one of which will be Matter, and the other three Vacuity, therefore *akmo* will conſiſt of four Parts, which will be all Vacuity, and the Portion of Matter in *aeno* will be to it's Vacuity as 1 to 7, and the ſame may be ſaid of the reſt of the Parts of Matter, and Vacuity in *aegf*, which therefore conſiſts of eight Parts, one of which will be Matter, and ſeven Vacuity, but *ebig* (= to *aegf*) which will be all Vacuity, conſiſts of eight Parts, and therefore there will be in *abif* 1, Matter, and 15, Vacuity, and the ſame may be ſaid of all the other Square Areolæ in *abcd*; and by the ſame Method we may proceed to a fifth or ſixth Diviſion, from whence we ſhall perceive that the Body will have 31 or 63 Times more Pores than ſolid Parts, as may be ſhewn by taking *pqle*, *uxye* for the leaſt of ſuch Parts.



That the foregoing Deſcription and Calculation do's not ſerve the Purpoſe for which it was contriv'd, but the Contrary.

§. 5. THIS is a true Pattern or Delineation of that Matter, which is now embrac'd and receiv'd for Authentick in Nature, which therefore in this Scheme we have deſcrib'd, and which explains the utmoſt Stretch of Genius, which the preſent Philoſophy makes uſe of, to get quit of a Difficulty ſo uneaſy to it, that is, to find out a ſubtle Matter, whilſt it affirms all Matter to be alike, which ſhall be continu'd in it's Parts, and yet infinitely Rare and Porous, for if that is not done, if Air, for inſtance, has one Part only of Matter for a thouſand Vacuities, and thoſe Parts of Matter are ſeparated and at a Diſtance from each other, for one Part of Matter we breath in, we ſhall meet with a Thouſand of Vacuum; and how it would be poſſible for us to breath at all in ſuch a Medium, any more than in an exhauſted Receiver, is not, nor can be accounted for: To evince therefore how a continu'd Subſtance, as Air, or Water, or Glaſs, or Gold, may have an infinite Number of Pores in it, ſo that the Space they take up ſhall be infinitely Greater than the ſolid Parts of Matter in them, this Calculation is contriv'd, which with what Succeſs it anſwers the Intention of it, we ſhall now Examine.

AND firſt, it is manifeſt, that in the Square *a b c d* the Parts of Matter are disjoin'd from each other by the intermediate Areolæ of Space or Vacuum, and that the Areolæ of Matter in the firſt Diviſion touch each other only in four ſingle Points, in *i*, *g*, *h*, and *c*, ſuppoſing this Alternation of Space and Matter to be continu'd to ſixteen Square Areolæ, in which the Reaſoning above will be the ſame.

SECOND, it is manifeſt, that in the ſecond Diviſion, the Areolæ of Matter recede farther from each other, and have more Vacuity betwixt them, and that they do not touch excepting in two Points, and many of them in one Point only.

THIRD, it is manifeſt, that in the third Diviſion the Areolæ of Matter ſtill farther recede from each other, and ſtill have more Vacuity betwixt them, and that their Points of Contact are fewer and rarer than in the Former.

FROM whence it is plain, that the farther the Diviſion is carry'd on, the ſmaller is the ſolid Part of Matter, which is ſuppos'd to be without any Vacuity, and the greater is the Vacuum round it, by which it is more remov'd from a Contact with any other Matter, that is, you diminiſh the Matter and increaſe the Vacuum, or Space about it.; and is not this a worthy and very extraordinary Solution of the Difficulty, which it in Fact confirms? We ſay it is a great Difficulty againſt a Vacuum and a Similar Matter, that there ſhould be ſo much void Space and ſo little Matter in Proportion, becauſe it do's not ſeem probable we could breath in ſuch a Medium; This Philoſophy anſwers that Difficulty by ſhewing, that there is ſo much void Space, and ſo little Matter in Proportion, and demonſtrates at the ſame Time, that theſe ſmall Parts of Matter in an infinitely rare Medium, may be infinitely remov'd from each other, for tho' the whole Square *a b c d* ſhould be infinitely ſmall, yet ſince the Particles of Matter in it are infinitely ſmaller, there will be the ſame Proportion betwixt Matter and Vacuity: And this is to ſolve Waters, not being compreſs'd in a Concave Sphere of Gold, and it's paſſing, as well as Quick-ſilver, thro' the Pores of it; This is to ſhew us how Light may be tranſmitted thro' Glaſs, how the Magnet may act upon Iron thro' all denſe Bodies, not Magnetick nor red Hot, as Gold, Silver, Lead, Glaſs, Water, without any Diminution of it's Vertue: And laſtly, how the gravitating Power of the Sun may be tranſmitted thro' the vaſt Bodies of the Planets without any Diminution, ſo as to act upon all their Parts to their very Centers with the ſame Force, and according to the ſame Laws, as if the Part, upon which it acted, were not ſurrounded with the Body of the Planet; Namely, becauſe all Bodies are more Porous than we imagine, and becauſe even in Gold it ſelf, there are more Pores and Vacuities than there is Matter, which Pores and Vacuities are before explain'd, and their Proportion to the ſolid Parts in Bodies, by the preceding Calculation.

AND now I ask could any Authority, beſides that of the preſent Philoſophy, ever ſupport ſo abſurd an Aſſertion as this, that Gold and conſequently all other denſe Subſtances here mention'd have more Pores than ſolid Parts? Why, we muſt bid adieu to our Senſes, and to all our Notices communicated from thence, if we muſt acknowledge this for a Truth, and affirm that Solidity, Plain, Viſible, and palpable Solidity is nothing but mere Space, this is a Philoſophical Tranſubſtantiation, which requires as much Faith to believe it, and as much Infallibility to maintain it, as the Popiſh or Religious one; if there was ſo much more Space and Vacuity in denſe Subſtances than Matter, as this Philoſophy repreſents, wou'd it not be as manifeſt, as we find it to be in the foregoing Scheme, which is made uſe of to eſtabliſh this Doctrine? Should we not perceive little Parcels of Matter diſpers'd with vaſt Spaces ſurrounding them, and not ſmall Spaces and Vacuities, and almoſt inviſible ſurrounded with vaſt Portions of Matter? And wou'd not ſuch a Matter as the preſent Figure exhibits

Principles of Natural Philoſophy Chap. 7. §. 8. Part I.

exhibits to us be eaſily compreſs'd, and the Particles of it ſoon cruſh'd and conſtipated into a cloſer Connexion? Wou'd Water ſweat out in ſmall Drops like Dew, or pour out in large and handſome Streams? Wou'd not ſuch a Conſtitution of Matter be as leaky and perfluous as a Sieve, and do's it not give us the Picture of one? Theſe Queſtions carry their own Anſwers with them, which is, that they need none; but we have argu'd againſt this kind of porous Matter in our *Principles of Natural Philoſophy*, when we conſider'd this very Experiment of the Impoſſibility of Compreſſing Water in a Concave Sphere of Silver, an Experiment made by the Academy *Del Cimento*. As to the Magnet, it is ſomething ſtrange when there are ſuch large Pores contriv'd for the Paſſage of it's Force, that it cannot get thro', if the ſolid Body is Magnetick, or Heated; one wou'd be apt to imagine there might be Room enough for it, if nothing elſe was neceſſary, but Vacuum, to it's Tranſmiſſion, but the Caſe is otherwiſe, as we ſhall afterwards ſhew.

As to the gravitating Power of the Sun acting upon every Particle of Matter in the vaſt Bodies of the Planets to their very Centers without any Diminution, it will be afterwards prov'd, that ſuch an Action is not certain in Fact, and is only a Creature form'd in a great Meaſure from the Principles of this Philoſophy, into which we are now inquiring.

The Difficulties endeavour'd to be ſolv'd by a Vacuum, and a Similar Matter, are better accounted for by a Plenum, and a Matter which is Heterogeneous.

§. 6. On the Contrary ſuppoſing a Plenum and an Heterogeneous Matter, moſt of theſe Difficulties obtain an eaſy Solution.

Sir Iſ. Newt. Princip. Prop. 19. Theorem. 14. §. 5. Lib. 2.

First, Water and even Air cannot be compreſs'd, the firſt little or not at all, and the laſt, excepting to a certain Degree, becauſe all Spaces according to the Philoſophy we propoſe are full, tho' not equally ſo, or rather, becauſe the Action of Water is Homogeneous in it ſelf, and Heterogeneous to all others, and therefore ſupports it ſelf in this Caſe of Compreſſion againſt any external Force, as much as any ſolid Body or Action will do, but if there is any Weaker or Heterogeneous Action as that of Air intermixt with that of Water, it may be compreſs'd, till the Action of the included Air becomes equal to that of Water; and thus the Subſtance or Action of Air, being intermingled with Heterogeneous Subſtances or Actions, may be compreſs'd till thoſe Heterogeneous Subſtances or Actions become equal to that of Air, but when any Subſtance or Action is Homogeneous it will be as impoſſible to Compreſs it, be it weaker or ſtronger in it's own Nature, as to make it what it is not; ſince if you afterwards Compreſs it, it being equally balanc'd in all it's Parts, it cannot admit of any Preponderancy, Alteration, or Motion in them, as is evidently prov'd in this Philoſophy, where it is ſaid, that, the Parts of an Homogeneous, and unmov'd Fluid, which is incloſ'd in an unmov'd Veſſel, and is compreſs'd on all Hands (ſetting aſide the Conſideration of Condenſation, Gravity, and all Centripetal Forces) are preſs'd equally on every ſide, and without any kind of Motion ariſing from that Preſſion, remain and continue in their own Places.

Second, Gold or Silver, upon the Compreſſion of the Water included, may give a Paſſage to it, without either of them having any Pores, in the ſame Way and Manner, as Paper or Parchment to a Needle, that is, where the Force impreſs'd is Superior to the reſiſting; thus tho' the Subſtance or Action of Gold or Silver is ſuperior to that of Water, yet ſince there is an additional Force by Compreſſion to Water, which, as we have ſaid, can have no effect to diſorder it, which is equally Balanc'd and Homogeneous, that additional Force makes the Water recoil upon the Heterogeneous Action or Subſtance of Gold or of Silver, and being made by that means Superior to it, it over-balances and penetrates thro' it, and forms, and points out a Paſſage to it ſelf, which was not made before by any imaginary Pores or Vacuities.

Third, Quick-ſilver enters into the Subſtance or Action of Gold by it's own innate Force and Volatility, by which it's Action is Superior to it, in the ſame manner, as Water into Salt, or Water compreſs'd into Gold, or *Aqua fortis* into Iron, that is, it makes it's own way into the Subſtance or Action of it, without being beholden to any Pores or Vacuities for it's Ingreſs; and the ſame may be ſaid of Light in it's Tranſmiſſion thro' Glaſs, or of the magnetick Force thro' the denſeſt Bodies, and the Reaſon, that the magnetick Force will not have the ſame effect upon Bodies which have a magnetick Force, and which are heated red Hot, is, becauſe thoſe Forces are more than a Balance to it, and repel it, by a ſuperior Degree of the Expanſive, which will be afterwards Explain'd.

Concerning the ancient Authorities relating to a Plenum and a Vacuum drawn from Plutarch *and* Laertius.

§. 7. As to what is ſaid concerning the Authority of the *Grecian* and *Phœnician* Philoſophers in the preſent Caſe, the Ancienteſt and moſt Eminent of whom made a Vacuum and Atoms, and the Gravity of them, the firſt Principles of their Philoſophy, and rejected a Plenum, this is ſo far from being True, that the Contrary is Certain and Evident., and what we affirm'd, True, *Princip. Philoſ. Pref.* §. 5.

Plutarch in his Account of the Opinions of Philoſophers in five Books, Chap. 18. Book the firſt, aſſures us, that all the Natural Philoſophers from *Thales* to *Plato* rejected a Vacuum, and that *Empedocles* allow'd of no Vacuity in Nature; that *Lucippus, Democritus, Demetrius, Metrodorus,* and *Epicurus* affirm'd an infinite Number of Atoms, and that a Vacuum was infinite in it's Extenſion, that *Ariſtotle* and alſo the *Stoicks* acknowledg'd a Vacuum beyond the World, but that all was a Plenum within it, *Laertius* alſo is a full and unconteſted Witneſs to the ſame Thing.

Concerning Pherecydes *and* Thales.

§. 8. *Diogenes Laertius* in his Lives of the Philoſophers Lib. I. Segm. 116. *Menagius*'s Edition, in the Life of *Pherecydes* the *Syrian* or *Phœnician*, tells us, that *Theopompus* affirms this *Pherecydes* was the firſt who writ concerning Nature and the Gods, in reſpect of which we are inform'd from another Author, that tho' he did not ſacrifice to any, yet he us'd to ſay, that he led as pure and vertuous a Life, as if he had ſacrific'd Hecatombs, and that there was a ſmall Book extant of his, when *Diogenes* writ of which he juſt mentions the Beginning, he alſo gives us an Epiſtle, which he ſent to *Thales*, and this is the Chief of what we have of *Pherecydes*, excepting that *Thales* the Author of the *Ionick* Sect in Philoſophy, and *Pythagoras* of the *Italick* were both of them his Auditors and Scholars, from whom therefore we may poſſibly be inſtructed in the Sentiments of the Maſter.

In the Life of *Thales*, Lib. I. Segm. 22. of the ſame Edition, it is ſaid that he was a *Phœnician* by Family, and that he apply'd himſelf to the Studies of Nature, and follow'd them chiefly in *Ægypt* as *Plutarch* writes, but left no Monument of his Parts, or his Sagacity in theſe Matters behind him, as ſome affirm, and that according to *Callimachus* he was the firſt who obſerv'd the leſſer Bear; but others think he writ concerning the Tropicks, and the Æquinoxes, and moſt are of Opinion, if *Eudemus* may be credited in his Hiſtory of Aſtrology, that he was the firſt, who ſearch'd into the Secrets of that Science, and who foretold the Eclipſes of the Sun, and the Changes of the Air, that *Xenophanes* and *Herodotus* admir'd him for it, and *Heraclitus* and *Democritus* atteſted the ſame, that ſome alledg'd he was likewiſe the firſt, who Taught, that the Soul was Immortal, that the Sun's Courſe was from Tropick to Tropick, and that the Lunar Orb was the ſeven hundred and twentieth Part of the Sun's Magnitude, that according to *Ariſtotle* and *Hippias* he attributed *Souls* to *inanimate Beings*, from what he obſerv'd of the Attractions of the Load-ſtone, and of Amber, that he learn'd the Precepts of Geometry in *Ægypt*, and was the firſt, who form'd a Rectangle Triangle by deſcribing it in a Semicircle, whoſe Baſis was the Diameter, and the Angle in the Circumference, as likewiſe who advanc'd the Doctrine of Triangles and Rectilineal Deſcriptions, tho' *Callimachus* aſcribes it in his Iambicks to *Euphorbus* the *Phrygian*, that he was a ſincere Promoter of the Intereſts of his Country, and preſerv'd it from Ruin by diſſuading the *Miletians* from joining with *Crœſus* againſt *Cyrus*, that he lov'd a private and retir'd Life, prefer'd Celibacy to Marriage, and contemn'd Riches, and planting of Olive-yards, ſaying, that *Water was the Principle of all Things, and that the World was animate and full of that Animation*, or of *Spirits*, that is by what forego's concerning the Magnet and Amber, of *Forces* which were unaccountable, or of Matter ſuppoſing it to conſiſt of ſuch Forces.

Concerning Anaximander *and* Anaximenes.

§. 9. In the Life of *Anaximander*, who as *Thales*, was alſo a *Mileſian*, and of the *Ionick* Sect, was Contemporary with him, and his Acquaintance Lib. 2. Segm. 1. of the ſame Edition, we are inform'd, that his Opinion was, that the Principle and Element of all Things was immenſe, and infinite, and therefore that it was *full*, not yet determining whether it was Air, or Water, or any Thing elſe, however, he eſteem'd it to be Changeable in it's Parts, tho' Immutable in the Whole, that the Earth was plac'd in the mid'ſt and Center of this infinite Plenum, and that it was Globular and Round, that the Moon was an opake Body, and deriv'd it's Light from the Sun, and that the Sun was at leaſt as big as the Earth, and conſiſted of the pureſt, and ſubtleſt, and moſt refin'd Fire; He firſt found out the Gnomon, and plac'd it according to *Phavorinus* in the Dials at *Lacedæmon*, in order to obſerve the Æquinoxes and

Solſtices, and was the firſt Perſon who meaſur'd the Ambitus of the Earth, and who made a Sphere.

Anaximenes, Lib. 2. Segm. 3. of the ſame Edition, was a *Mileſian* likewiſe, the Scholar of *Anaximander,* and a Correſpondent of *Pythagoras,* there being extant two Letters of his to him, in one of which he highly extols *Thales,* gives an Account of his falling down a Precipice, when he went out one Morning with his Maid, as his Cuſtom was, to make Obſervations in the Heavens, not minding the Situation of the Place, which was the Occaſion of his Death, according to the *Mileſians,* ſays, he acquieſces in his Doctrine, and believes him to have found out the Principle of the Univerſe; in the other he complains of the Tyrannical Government amongſt the *Mileſians,* and that they were in a continual Fear of an Invaſion from the *Medes,* upon which account he had but little Heart for Aſtronomical Obſervations, who was under conſtant Apprehenſions of Death or of Slavery, and he commends *Pythagoras*'s Prudence for removing in ſuch hazardous Times from *Samos* to *Croton* and *Italy,* where he was regarded and eſteem'd. This Perſon taught that Air was the Principle of all Things, that it was Infinite, and that therefore Space was *full* of it, and that the Stars did not move over the Earth, but about it.

Concerning Anaxagoras *and* Archelaus.

§. 10. *Anaxagoras,* Lib. 2. Segm. 6. was of *Clazomene* in *Ionia* on the ſame Continent with *Miletus,* and the Scholar of *Anaximenes,* and whereas all before him had affirm'd Matter or the ὕλη to be the firſt Principle, that is the Infinite or the Plenum, he added an Intelligence and a Mind to it, and was therefore call'd the Mind or the Intelligence, and he begins his Philoſophy thus; all Things exiſted together, and at once, that is, there was an Univerſal Plenum of Being, which exiſted of it ſelf, and together, and in one time, or always, and afterwards the Mind or Intelligence diſpos'd it into Beauty, and order, and form'd, and conſtituted the World; he is ſaid to have been Noble by his Family, and Rich in his Poſſeſſions, but particularly eminent for the Greatneſs of his Mind, in quitting his whole Patrimony and reſigning it to his Relations, his farther Opinions were, that the Sun was a *red hot Iron,* heated quite thro', and Greater than the *Peloponneſus,* that the Moon was Inhabited, and had it's Hills and it's Valleys, ἀρχὰς δὲ τὰς ὁμοιομερείας, καθάπερ γὰρ ἐκ τῶν ψηγμάτων λεγομένων τὸν χρυσὸν συνεστάναι, οὕτως ἐκ τῶν ὁμοιομερῶν μικρῶν σωμάτων τὸ πᾶν συγκεκρίσθαι, namely, that the Principles of Bodies, of which they conſiſt, were Homogeneous to the whole, that is, that the Parts were of a like Nature with the Bodies which they compos'd, as Gold is made up of the ſmall Raſures or Fileings into which it may be divided, and in like manner, that the whole Univerſe was made up of Bodies Homogeneous to the whole, which conſiſts of them, and into which it may be likewiſe divided, and as to Motion, that the Mind or Intelligence was the Origine of it; that heavy Bodies tended downwards, as Earth, and that light ones, as Fire, aſcended upwards, but that Water and Air affected a middle Situation, for thus Water lies above the Earth, and is eaſily converted into Vapours by the Sun; that the Pole was originally in the Vertex, or directly over our Heads, and the Stars were carry'd round it's Axis, but that it afterwards receiv'd it's Inclination, that the Galaxy or *Via Lactea* was owing to a Reflection of the Sun's Light, and not to innumerable Stars ſhining and diſpers'd in it, τοὺς δὲ κομήτας σύνοδον πλανητῶν, φλόγας ἀφιέντων, τούς τε διάττοντας οἷον σπινθῆρας ἀπὸ τοῦ ἀέρος ἀποπάλλεσθαι, that the Comets were the Congreſſion or Concourſe of wandering Stars, which emitted Flames, and that theſe Emications, like the Twinkling in the Stars, were ſtruck by the Vibrations of the Air, that Winds were cauſed from the Rarefaction of the Air by the Sun, that Thunder aroſe from the Daſhing together and the Colliſion of Clouds, and that Lightenings were deriv'd from the Attrition of them; that Earth-quakes were made by the Airs being included in the Cavities of it, and endeavouring to return to the Exterior Parts, and to the Air above them; that Animals were firſt produc'd from Moiſture and Heat, but afterwards from Male and Female; that all the Heavens were form'd of Stones, and that by their Revolution they were kept in their Orbit, which otherwiſe wou'd fall from thence, [which poſſibly might be no more than that the Planets were ſolid and heavy Bodies, and were revolv'd in their Orbits, and that they wou'd ſink to the Center, if not kept up by ſuch a Revolution, and it is not improbable, that the Story of his foretelling a Stone falling down from the Heavens or the Sun about the River *Ægos,* was nothing more than a Fiction of ſome, who did not underſtand his Principles;]

Sir Iſ. Newt. Princip. Prop. 41. Lib. 3. Pag. 466. Edit. 2.

Deſcartes's Princip.

Sir Iſ. Newt. Princip.

This is however certain, that his Philoſophy was charged with Impiety, that he was accus'd by *Cleon* for aſſerting, that the Sun was a red hot Iron, and defended by his Scholar *Pericles* the famous *Athenian*, that he was notwithſtanding fin'd five Talents and condemn'd to Baniſhment, and afterwards, as a Betrayer of his Country, ſentenc'd to Death, all which he bore with an invincible Patience and Conſtancy.

Archelaus, Lib. 2. Segm. 16. was alſo a *Mileſian*, the Scholar of *Anaxagoras*, and the Maſter of *Socrates*, and the firſt who introduc'd Natural Philoſophy into *Athens* from *Ionia* (ſo that *Anaxagoras* do's not ſeem by this to have publickly taught it in *Athens*) and it is ſaid to have ended with him, by *Socrates*'s advancing Morality and Ethicks in it's Room, the Foundations and Principles of which he is thought to have learn'd from this Philoſopher, who reaſon'd in his Lectures, concerning Laws, and what was Vertuous and Commendable, and what was Juſt; His Opinions were, that there were two Cauſes of Productions or Generations, Hot and Cold, that Animals and Men alſo were form'd from a Mud or ſlimy Matter, that Law and Preſcription, and not Nature was the Meaſure of what was Juſt, or Baſe and Diſhoneſt, that Voice and Sound was from the Percuſſion of the Air, that the Sea ſtood in a Concave Baſon, and the Water ouz'd thro' the Earth into it, that the greateſt of the Stars was the Sun, and that the τὸ πᾶν or the Univerſe, or the ὕλη, (for we hitherto find no Mention of Space) was Infinite.

Concerning *Socrates, and* Plato, *and* Ariſtotle.

§. 11. *Socrates* turn'd all his Philoſophy upon Morality, but no doubt had ſome Opinions and Notions concerning Nature, and as he was a Diſciple of the *Ionick* Sect, and his Maſter *Archelaus*, who all affirm'd a Plenum, and as *Plato*, who was *Socrates*'s Auditor at twenty Years old, and join'd the Morality of his Maſter with the Philoſophy of *Anaxagoras* and *Thales*, affirm'd the ſame Doctrine, it is reaſonable to think that *Socrates* acquieſce't in it, tho' his Genius and Studies led him to inquire more into the Mind and Intelligence of *Anaxagoras*, and the Vertue and Vice of *Archelaus*, than into their Diſputes concerning Matter, and the Conſtitution of the Univerſe.

FROM *Socrates* we have a long Series of Philoſophers, namely, *Xenophon*, *Æſchines*, *Ariſtippus*, *Phædon*, *Euclides*, *Diodorus*, *Stilpo*, *Crito*, *Simon*, *Glaucon*, *Simmias*, *Cebes* the Author of the Table, and *Menedemus*, till we come to *Plato*, who all buſy'd themſelves in Ethicks, Logicks, Oeconomicks, or Politicks, and which we may juſtly ſuppoſe were only Efforts towards a Reformation of Government, and Manners againſt Polytheiſm and Paganiſm, in which Cauſe *Pherecydes* firſt appear'd, a *Syrian* or *Phœnician*, inſtructed, it is likely, by the *Ægyptians* or the Books of *Moſes*, and after him *Thales*, *Anaximander*, *Anaximenes*, and *Anaxagoras* by aſſerting Philoſophy and one infinite Being, in Oppoſition to all the Vanities of the Heathens, and their Plurality of Gods, in the Courſe of which Doctrines, and the aſſerting of them, *Anaxagoras* and *Socrates* loſt their Lives.

Plato, Lib. 3. Segm. 69. δύο τῶν πάντων ἀπέφηνεν ἀρχὰς θεὸν ϗ ὕλην, ὃν ϗ νοῦν προσαγορεύει ϗ αἴτιον, εἶναι δὲ τὴν ὕλην ἀσχημάτιστον ϗ ἄπειρον, ἐξ ἧς γίνεσθαι τὰ συγκρίματα, ἀτάκτως δέ ποτε αὐτὴν κινουμένην, ὑπὸ τοῦ Θεοῦ φησὶν εἰς ἕνα συναχθῆναι τόπον, τάξιν ἀταξίας κρείττονα ἡγησαμένου, τραπέσθαι δὲ τὴν οὐσίαν ταύτην εἰς τέτταρα στοιχεῖα, πῦρ, ὕδωρ, ἀέρα, γῆν, ἐξ ὧν αὐτόν τε τὸν κόσμον ϗ τὰ ἐν αὐτῷ γεννᾶσθαι, That is, *Plato* held, and it was his Doctrine, that there were two Principles of all Things, God and Matter, whom he alſo call'd the Mind or Intelligence, and the Cauſe; that Matter was without any Form and Infinite, and from it the ſeveral Concretions, and particular Bodies or Subſtances of it were made, that originally there were Motions in this Matter but very Diſorderly and Irregular, and that by God it was reduc'd into one Place, (that is, according to the Account given us by *Moſes*, each Portion of Matter ſeparated to it's own Kind or Species) God, or the Mind or Intelligence, preferring Beauty and Order to the Contrary, and therefore that this Eſſence, or Subſtance, or Plenum was converted into four Elements, Fire, Water, Air and Earth, of which Elements the World, and all Things in it were form'd and made: As to the Character of *Plato* and his Writings, they are ſo well known, that there is no occaſion for me to tranſcribe his other Opinions, but it is very manifeſt and plain, that he exactly agrees with *Anaxagoras* in his Matter, and his Mind or Intelligence, and the Diſpoſition of the Former, by the Latter, into the Frame of the World in which we now ſee it, and therefore it is very reaſonable to believe, that *Socrates*, who was a Diſciple of

Archelaus, the Scholar of *Anaxagoras*, and who was the Maſter of *Plato*, enter'd into the ſame Notions.

FROM *Plato* Lib. 4. there runs on an Order of Names, *Speuſippus*, *Xenocrates*, *Polemo*, *Crates* the *Athenian*, and Scholar of *Polemo*, *Crantor*, *Arceſilaus*, *Bion*, *Lacydes*, *Carneades*, *Clitomachus*, till we come to *Ariſtotle*, who ſpent their Time in writing of Commentaries and Dialogues on Ethical Subjects moſtly, in Diſputing, and in Eloquence, without any great Advantage to the Knowledge of Nature, in which we may ſuppoſe they held much the ſame Tenets with *Anaxagoras* and *Plato*.

Ariſtotle, Lib. 5. Segm. 1. was of *Stagira* on the *Strymonian* Bay, and the Scholar of *Plato*, Segm. 32. he held that God was Incorporeal, as *Plato* before him, that his Providence extended to the Heavens, and that he was Immoveable, he affirm'd four Elements, Air, Earth, Fire, and Water, that the Heavens, and the Heavenly Bodies conſiſted of a Matter different from all theſe, which was his *Quinta Eſſentia*, and that it had a peculiar Motion belonging to it, namely, an Orbicular one, from whence it is Evident, that as *Anaxagoras* and *Plato*, ſo he aſſerted a Plenum of Matter, and a Mind or Intelligence which agitated and mov'd it, beſides it is confeſs'd on all Hands, that he maintain'd the Material World was Infinite and Eternal, and conſequently, that it was *full*, excepting that *Plutarch* denies it, who it is evident was much more Converſant in the Actions and Sayings of Eminent Men, than Wiſe or Judicious in the Sentiments and Opinions of Philoſophers.

Theophraſtus was the Scholar of *Plato* firſt, and afterwards of *Ariſtotle*, Lib. 5. Segm. 36. and therefore it may be reaſonably preſum'd that his Opinion was the ſame in this Point, in which he found both his Maſters to agree, he writ an immenſe Number of Books upon all Subjects, tho' we have nothing remaining of him excepting a ſmall Manual of Characters, and his Volumes are ſaid to contain in the Whole two Hundred and thirty Thouſand eight Hundred and eight Verſes or Diſtinctions.

After him, Lib. 5. Segm. 58, &c. come *Strato*, *Lycon*, *Demetrius*, *Heraclides*, and Lib. 6. Segm. 1, &c. *Antiſthenes*, *Diogenes*, *Monimus*, *Oneſicritus*, *Crates* the *Theban* and Scholar of *Diogenes*, *Metrocles*, *Menippus*, *Menedemus*, amongſt whom we find no mention of a Vacuum, but it is very probable they acquieſce't in the Doctrine of a Plenum, ſuitable to what had been taught by *Anaxagoras*, *Plato*, and *Ariſtotle*, from whom they deriv'd their Philoſophy.

Concerning Zeno *and* Cleanthes.

§. 12. *Zeno*, Lib. 7. Segm. 1. was of *Cittium* in *Cyprus* a ſmall *Greek* Town, and inhabited by a Colony of *Phœnicians*, and from thence was call'd a *Phœnician*, and by ſome an *Ægyptian* for the ſame Reaſon, he was the Father of the *Stoick* Philoſophy, as *Plato* of the *Academick*, *Ariſtotle* of the *Peripatetick*, and *Diogenes* of the *Cynick*, and his addicting his Mind to the Studies of Philoſophy, was from his bringing ſome Merchandize in a Ship from *Phœnicia* to *Athens*, where he loſt all by a Wreck which he ſuffer'd at the *Piræus*, he was thirty Years old when he came into *Athens*, and ſiting down in a Bookſeller's Shop, and Reading the ſecond Book of *Xenophon*'s Commentaries, he was ſo much pleas'd with it, that he inquir'd where he might meet with ſuch Men, *Crates* the *Cynick*, who had been *Diogenes*'s Scholar, accidentally paſſing by at that Time, the Bookſeller pointed to him, and bid him follow him, which he accordingly did, and became for ſome time his Auditor, whom afterwards he left, and for Twenty years from thence was a Diſciple of *Stilpo*, *Xenocrates*, and *Polemo*, and from this Philoſopher it is, and his Followers, that we firſt hear of a Vacuum amongſt thoſe of the *Ionick* Sect, and it is not impoſſible, but this may be one of the *Phœnicians* whom the preſent Philoſophy intends, when it mentions them as Patrons of that Doctrine; If it were ſo, there wou'd be no great advantage of Authority to this Philoſophy from a Sect of Men, as the *Stoicks*, who were ſo far from explaining Nature, that they went farther from it, and embrac'd more Romantick and Extravagant Notions concerning it, than any other Denomination of Philoſophers; Thus their making the World a real Animal, and aſſerting that there was no Evil in Pain, are ſufficient Evidences of it.

BUT it is alſo to be conſider'd, that the Vacuum they contended for was nothing like that, which the preſent Philoſophy eſpouſes, and ſeems to be little more than an Æthereal Matter, and the Quinteſſence of *Ariſtotle*. For Segm. 134. to 141. we find, that there are two Principles of all Things affirm'd, τὸ ποιοῦν ϗ τὸ πάσχον, the

Efficient, and the Patient; That which is Paſſive is the ὕλη or Matter, ἄποιος οὐσία, a Subſtance in general without any particular Quality or Property, ſo that it is not Gold, or Air, or Water, or Earth, or Fire, but an univerſal Matter, or the *Prima Materia* of the *Logicians*, out of which the *Materia Secunda* was form'd; And that which is Active is the Wiſdom and Reaſon obſervable in it, which diſpoſes it into Order, and to ſeveral Uſes and Ends, which Wiſdom and Reaſon is God; Now this ſeems to be the very Doctrine of *Anaxagoras* and *Plato*, who affirm'd a Plenum, and a Mind or Intelligence belonging and annex't to it; This will farther appear from what follows in this Segment, where it is ſaid, that there is a Difference betwixt the Principles and Elements of Things, ſince the firſt, the ἀρχαὶ are ἀγέννητοι ϗ ἄφθαρτοι, they are unproduc'd and incorruptible, the laſt, the στοιχεῖα, κατὰ τὴν ἐκπύρωσιν φθείρονται, that is, by the Influences of the Sun, Water is rais'd into Vapours, the Earth is parch'd, the Air heated, and Elementary Fire extinguiſh'd, and therefore theſe Elements are Corruptible, but God and Matter are unproduc'd and Incorruptible, if Matter therefore is unproduc'd and Incorruptible, as God himſelf, how is it poſſible, in the Notion of the *Stoick* Philoſophy, that it ſhould not be Infinite, and Eternal, and therefore that the World ſhould not be full of it? Another Diſtinction, which is ſaid to be betwixt Principles and Elements, is στοιχεῖα σώματα εἶναι ϗ μεμορφῶσθαι, τὰς δ' ἀρχὰς ἀσωμάτους ϗ ἀμόρφους, that the Elements, as Air, Water, Earth, and Fire are Bodies, and have a certain Form affixt to them, by which they become ſuch a Kind of Matter, and of a definite Shape and Subſtance, but that the Principles, as God and Matter, are Incorporeal, and without Form or any definite Shape or Subſtance; If therefore Matter is Incorporeal, it is plain the Vacuum of the *Stoicks* was Matter, tho' not ſuch as Corporeal Beings, or any Syſtems or Maſſes of groſs Matter, conſiſt of, it was the *Quinta Eſſentia* of *Ariſtotle*, or the *Prima Materia* of the *Logicians*, as we before obſerv'd; If farther this Matter was ἄμορφος, undefin'd, without any particular Shape or Subſtance, it muſt be Infinite, and by Conſequence the *Stoicks* muſt have held a Plenum of a moſt ſubtle, confus'd, and undiſtinguiſh'd Matter, out of which the Mind or God, they afterwards tell us, produc'd the four Elements above-mention'd; they likewiſe taught, that the World was properly a Quality of the univerſal Subſtance, ἐστι κόσμος ὁ ἰδίως ποιὸς τῆς τῶν ὅλων οὐσίας, that the World was finite, rul'd and govern'd by the Providence of God, that it was one, and of a Globular Figure, ἐν δὲ τῷ κόσμῳ μηδὲν εἶναι κενὸν, ἀλλ' ἡνῶσθαι αὐτὸν, and that in it there was no Vacuum, but all Things in it were united and cemented together, but that beyond it, there was an immenſe Vacuum, which was Incorporeal, and that Incorporeal was what contain'd Bodies, but not contain'd by them, from whence it is evident, that they allow'd no Vacuum in the World, which yet the preſent Philoſophy aſſerts, but thought the Fire, which they plac'd in the Heavens, that is in the uppermoſt Region, Air, which they diſpos'd immediately under it, Water, which was the next, and Earth, which was the loweſt, were united and connected together, ſo as to make one continu'd tho' Difform and Diſſimilar Plenum, as conſiſting of Heterogeneous Matters and Subſtances; nor is it manifeſt, that the Vacuum beyond this World was meer Space, only an univerſal Subſtance, out of which the particular Ones of the World were made, it was Incorporeal, that is, had none of the Bodies or diſtinct Syſtemes of Matter in it, which were found in the World, and it was what contain'd Bodies as ſurrounding and inveſting them, but was not contain'd by them, becauſe it was ἄπειρος and Immenſe.

Cleanthes, famous for his indefatigable Labour and his Study, was a Scholar of *Zeno*, Lib. 7. Segm. 168, &c. and was entirely attach't to his Doctrines.

Sphærus ſeems to have been an Auditor of *Zeno* firſt, and after of *Cleanthes*; and *Chryſippus*, tho' an Auditor of each, diſſented from both in many Particulars, he was a celebrated Logician and Diſputant, but it do's not appear, that he made any great Advances in Nature and Philoſophy, and here ends the *Ionick* Sect, who it is very plain were unanimouſly for a Plenum, and even *Zeno* in the World, and in the Senſe which I have explain'd, beyond it: We ſhall now proceed to the *Italick* Sect, which was another Branch of the *Syrian* or *Phœnician* Philoſophy taught by *Pherecydes*, of which his Scholar *Pythagoras* was the Chief, as *Thales*, and after him *Anaxagoras* of the *Ionick*.

Concerning Pythagoras *&* Empedocles.

§. 13. *Pythagoras,* Lib. 8. Segm. 1, 2, 3, &c. whether a *Syrian, Samian,* or a *Tuſcan,* is a Queſtion, was the Scholar of *Pherecydes,* and after his Death, of *Hermodas* at *Samos;* when he was young, out of a great Affection and Inclination to Knowledge, and the being inform'd, he left his native Country, and was initiated almoſt in all the Myſteries of the *Greeks* and *Barbarians,* at length he came to *Ægypt,* and learn'd their Language, and from thence into *Chaldæa,* where ſome affirm he had *Zoroaſtres* for his Maſter, he afterwards return'd to *Samos,* and finding his Country oppreſs'd by the Tyranny of *Polycrates,* he went to *Croton* in *Italy,* where he was Celebrated for his Number of Scholars, and the Wiſdom of his Laws, which he gave to the *Italians,* he had Brothers, *Eunomus* and *Tyrrhenus,* his Father, *Mneſarchus,* and a Servant, whilſt he continu'd at *Samos,* named *Zamolxis,* who being releas'd from his Servitude, taught the Immortality of the Soul amongſt his Country-men the *Getæ,* and was worſhip'd by 'em as a God; Segm. 25. his Doctrine was, ἀρχὴν μὲν τῶν ἁπάντων μονάδα, ἐκ δὲ τῆς μονάδος, ἀόριστον δυάδα ὡς ἂν ὕλην τῇ μονάδι αἰτίῳ ὄντι ὑποστῆναι, ἐκ δὲ τῆς μονάδος, καὶ τῆς ἀορίστου δυάδος, τοὺς ἀριθμούς, ἐκ δὲ τῶν ἀριθμῶν, τὰ σημεῖα, ἐκ δὲ τούτων, τὰς γραμμάς· ἐξ ὧν τὰ ἐπίπεδα σχήματα, ἐκ δὲ τῶν ἐπιπέδων τὰ στερεὰ σχήματα, ἐκ δὲ τούτων τὰ στερεὰ σώματα, ὧν καὶ τὰ στοιχεῖα εἶναι τέτταρα, πῦρ, ὕδωρ, γῆν, ἀέρα, ἃ μεταβάλλειν δὲ καὶ τρέπεσθαι δι᾽ ὅλων, καὶ γίνεσθαι ἐξ αὐτῶν κόσμον, ἔμψυχον, νοερόν, σφαιροειδῆ, μέσην περιέχοντα τὴν γῆν, καὶ αὐτὴν σφαιροειδῆ καὶ περιοικουμένην, that the Principle of all Things was one, that is, that the Univerſe was one individual Thing, which contain'd every Thing in Nature, that this one Nature was divided into Two, into Matter, and into the Intelligence or the Mind the Author of it, and that this Duality, God and Matter, were Interminate, or Infinite, and from this Duality aroſe Numbers, from thence Points, and from thence Lines, and from thence Surfaces, and from Surfaces, Solids, according to the Mathematick Way of Generation, from Solids, Bodies, or Corporeal Subſtances, and from them the four Elements, Fire, Water, Earth, and Air, which poſſeſs'd and paſs'd thro' all Things, that is, which, one or other, were every where diſpers'd thro' the vaſt Immenſum, and conſtituted the World, which had a Soul, and a Mind, or Underſtanding belonging to it, was Globular, contain'd the Earth in the middle of it, which was it ſelf Globular and Inhabited all round, ſo as to have Antipodes; *Plutarch* likewiſe affirms this to be the Notion of *Pythagoras,* and *Aldobrand* and *Menage* very truly Remark that all Philoſophers, as well as *Pythagoras,* maintain'd that the World was animated, and had an Intelligence annex'd to it, excepting *Democritus* and *Epicurus;* ſo that all the Philoſophers, who affirm'd a Plenum, acknowledged an infinite Mind and Intelligence, which actuated it, and the two Philoſophers, and their Followers, who deny'd this Plenum, and aſſerted a Vacuum, were thoſe, who deny'd ſuch a Mind or Intelligence; and we may obſerve that theſe were Men ſtrict in their Reaſon, & ſerious in their Philoſophy, Vertuous in their Lives, and Pious towards God, and the *Pythagoreans* in particular are celebrated for their Precepts of Piety, Morality and Vertue; and in this ſtrain went Philoſophy, till Laugh and Grimace, Irreligion and Atheiſm began to be ſubſtituted in it's Room, by *Democritus* and *Epicurus,* the firſt Promoters of Atoms and a Vacuum.

I ſhall only juſt mention the Names of the Philoſophers, who came after *Pythagoras,* and then proceed to the Sentiments of *Democritus.*

Empedocles, Lib. 8. Segm. 54. was the Auditor of *Pythagoras,* and Segm. 56. of *Parmenides,* at the ſame Time as *Zeno,* he afterwards was a Scholar of *Anaxagoras,* and *Pythagoras,* and propos'd the Gravity of Life, and of Habit of the firſt, and the Reaſonings upon Nature of the laſt for his Imitation, and according to *Ariſtotle,* he was the firſt Inventor of Rhetorick or Oratory, as *Zeno* was of Logicks or Dialecticks.

Epicharmus of *Coos,* Segm. 78. was an Auditor of *Pythagoras,* and *Archytas* the Geometer mention'd by *Horace,* Segm. 79. was a *Pythagorean,* and had an Intercourſe with *Plato,* by Letter, as is there recited, and the Letters betwixt them ſet down at large.

Alcmæon of *Croton,* Segm. 83. was alſo an Auditor of *Pythagoras;* and *Hippaſus* of *Metapontium,* and *Philolaus* of *Croton,* Segm. 84. were *Pythagoreans; Eudoxus,* Segm. 86. learn'd his Geometry from *Archytas,* and was an Auditor of *Plato.*

Heraclitus, Lib. 9. Segm. 1. was of *Epheſus,* it is not ſaid of what Sect he was, he blam'd many Things, but did not advance much, he had ſome Sayings, and ſmall Stories are told of him, which is the Caſe of the other Philoſophers, in which their

Hiſtory many Times chiefly conſiſts, according to *Laertius*; from him follow Lib. 9. Segm. 18, &c. *Xenophanes*, *Parmenides*, *Meliſſus*, another *Zeno*, *Leucippus* an Auditor of the *Stoick*, till we come to *Democritus*.

Concerning Democritus *and* Epicurus.

§. 14. *Democritus*, Lib. 9. Segm. 34, &c. was of *Abdera* in *Thrace*, on the Shore of the *Ægean*, betwixt the Rivers *Neſſus* and *Hebrus*, as ſome, and as others, of *Miletus*, it is ſaid he learn'd Theology and Aſtrology of the *Chaldeans*, when a Boy, and afterwards join'd himſelf to *Leucippus* and *Anaxagoras*, being younger than the latter about forty Years; he us'd to ſay, that what *Anaxagoras* had writ of the Sun and Moon was old, that his Opinions concerning them were not his own, but ſtol'n and purloin'd from Philoſophers, that were much ancienter; he likewiſe endeavour'd to detract from his Philoſophy in Relation to his Compoſition of the World, and his Mind or Intelligence annext to it, being implacably bent againſt, and an adverſary to him, becauſe he wou'd not ſuffer him to continue in the Number of his Scholars; it is ſaid, that he went into *Ægypt* to the Prieſts there to learn Geometry, and into *Perſia* to the *Chaldeans*, and as far as the Red-Sea, and that he had an Interview and Conference with the *Gymnoſophiſts* in *India*, he was the younger Brother of Three, and when a Diviſion was made of their Father's Subſtance into three Portions, he took the leaſt, which conſiſted all of Money, for which he ſhou'd have occaſion in his Travels, which was eſteem'd by his Brothers to have been a piece of Art and Craft in him, he was very much addicted to his Studies, and ſhut himſelf up in a ſmall Cell in a Houſe encompaſs'd with a Garden to proſecute them with more Vigour and leſs Interruption, he came to *Athens*, but was not willing to be known out of Modeſty, and a contempt of Glory, ſo that he knew *Socrates* tho' unknown by him, yet ſome affirm he never came to *Athens*; he was perfectly vers'd in all Natural, Moral, and Mathematick Knowledge, and in the Liberal Arts and Sciences, *Thraſyllus* relates, that he was a Follower of the *Pythagoreans*, and a great Admirer of *Pythagoras*; he liv'd in a very retir'd and ſolitary Manner, and us'd to be frequently amongſt the Sepulchers, which he might almoſt ſeem to inhabit; After his Return from his Travels, he appear'd in a very mean Condition, having ſquander'd away his whole Patrimony, till he foretold certain Matters, whoſe Event verify'd his Predictions, for which by ſeveral he was thought worthy of divine Honours, and to avoid the Ignominy of wanting a Grave, which by the Laws he was depriv'd of, for ſpending his Patrimony, he recited his Diacoſm, which was much the Beſt of all his Works, and for which he was honour'd with a reward of five Hundred Talents, and with Images of Braſs erected to him, he liv'd to his Hundred and ninth Year, and dy'd with great Complacency of Mind, and with little Pain; *Ariſtoxenus*, in his Hiſtorical Commentaries, ſays, that *Plato* wou'd have burnt what Writings he cou'd meet with of *Democritus*'s, which he collected for that Purpoſe, but that he was hinder'd by *Amyclas* and *Clinias* who were *Pythagoreans*, and who told him, that it wou'd ſignify little, ſince Copies of them were preſerv'd in ſeveral Hands; his Doctrines were, ἀρχὰς εἶναι τῶν ὅλων ἀτόμους ϗ κενόν· τὰ δ' ἄλλα πάντα νενομίσθαι δοξάζεσθαι, ἀπείρους τε εἶναι κόσμους ϗ γενητούς, ϗ φθαρτούς· μηδέντε ἐκ τοῦ μὴ ὄντος γίνεσθαι, μηδὲ εἰς τὸ μὴ ὂν φθείρεσθαι, ϗ τὰς ἀτόμους δὲ ἀπείρους εἶναι κατὰ μέγεθος ϗ πλῆθος· Φέρεσθαι δ' ἐν τῷ ὅλῳ δινουμένας, ϗ οὕτω πάντα τὰ συγκρίματα γεννᾶν, πῦρ, ὕδωρ, ἀέρα, γῆν· εἶναι γὰρ ϗ ταῦτα ἐξ ἀτόμων τινῶν συστήματα, ἅπερ εἶναι ἀπαθῆ ϗ ἀναλοίωτα διὰ τὴν στερρότητα. That the Principles of all Things were Atoms and a Vacuum, and that all other Things reſted in Opinion only, that there were innumerable Worlds, which were form'd and diſſolv'd by the Concourſe or Diſunion of theſe Atoms, that nothing could be produc'd from that which was not in Being, nor diſſolv'd into that which never had an Exiſtence, that therefore every Thing was made from Atoms or ſmall Particles of Matter, which always exiſted, and was ultimately reſolv'd into them, that theſe Atoms were infinite both in their Number and their Magnitude, or in the Extenſion of them all together, and that they were carry'd and whirl'd about in the Univerſe one amongſt another, from whence ſeveral Concretions of them were diſpos'd into Fire, Water, Air, and Earth, and that many Syſtemes which were compounded of certain of theſe Atoms or Particles of Matter, were cemented ſo ſtrongly, and conſiſted of ſuch ſolid Atoms and Particles, that they were not liable to Corruption, or were in the leaſt affected by any External Impreſſions upon them; he farther taught, that the Sun and Moon were form'd from the Motion, and at length the Concretion of theſe ſolid and obſtinate

Particles of Matter, or Atoms, and that the Soul, by which the Body or the Univerſe was animated, was ſo likewiſe, and the Mind or Intelligence of *Anaxagoras* he took to be no other, and that Viſion was cauſ'd by the Images of Things being impreſs'd upon our Eyes; alſo, that all Things were neceſſarily form'd and made by this Concourſe of Atoms without any voluntary or intelligent Agent; and that the End, which every one ſhould propoſe to himſelf, ſhould be a quiet and ſerene State of Mind, not as ſome have interpreted him Pleaſure, but a Mind continually happy in a perfect Tranquillity and Conſtancy of it's Thoughts, and not diſturb'd by any Fear or Superſtition, or any other Paſſion which may create it's Diſorder. And this is the firſt Syſteme of Atoms, and a Vacuum, and of all Things being produc'd by Neceſſity, and of a World without an Intelligence, which we find amongſt the Philoſophy of the Ancients, and from whence it is manifeſt, that Atheiſm, and Atoms, and a Vacuum had their Riſe and their Birth together.

Protagoras, Lib. 9. Segm. 50, &c. was of *Abdera*, and an Auditor of *Democritus*; he affirm'd his Principles in a very confus'd Manner, that Man was the Meaſure of all Things, that the Soul was nothing but Senſation, and that whether there were any Gods or not, he could not determine, for which Aſſertions he was baniſh'd *Athens*, and his Books publickly burnt in the *Forum*, the *Præco* or Cryer making Proclamation thereupon, and ſearch was every where order'd for them in what Hands ſoever they ſhould be found; he was a mercenary Philoſopher, and ridiculous Stories are told of him upon that Account.

Anaxarchus, Lib. 9. Segm. 58, &c. was likewiſe of *Abdera*, whoſe chief Doctrine was, that he knew, that he knew nothing, which might not be improbable.

The next is *Pyrrho*, Lib. 9. Segm. 61. the famous Sceptical Philoſopher, he was at firſt a Painter, and afterwards was the Auditor of *Dryſo*, the Son of *Stilpo*, and then of *Anaxarchus*, to whom he adher'd in all his Notions, ſo that he went to the *Gymnoſophiſts* in *India*, and to the *Magi* in *Perſia*, with whom he confer'd; his Doctrine was, that he cou'd not make a peremptory Deciſion upon any Thing whatſoever, nor was there any Thing which we could fully Comprehend, that there was no ſuch Thing as Commendable or Baſe, or Juſt or Unjuſt, that Truth was a meer Chimæra, and that the Rules by which Men judg'd and acted were thoſe of Law and Cuſtom, which were the Meaſure of Virtue and Vice, of Right and Wrong, and that there was not any one Thing which was really preferable, or one ſhould ſooner chuſe than another; agreeably to theſe Sentiments he form'd his Life and Manners, avoiding nothing which came in his way, whether Chariots, or Carriages, or Dogs, or Precipices, becauſe his Opinion was, that you ſhould not truſt your Senſes, and therefore not reſign your ſelf to the Conduct of 'em, and he was often preſerv'd from great Dangers and Inconveniences, to which he was expos'd upon this Account, by his Friends, that follow'd him; he was mighty deſirous of being, or being thought to be a good Man, and he liv'd to the Age of Ninety, and he us'd to ſay, that it was very hard to put off the Man, but Endeavours were to be made to do it to the utmoſt of our Power, in our Actions, and if that could not be, by our Reaſon even againſt Things, as they might appear to us.

Mr. Lock's Eſſay on Human Underſtanding.

Deſcartes's Meditat. and Mallebranche Recherche de la Verité.

After him come *Timon*, and *Sextus Empyricus*, Lib. 9. Segm. 109. and from them we are brought to *Epicurus*.

Epicurus, Lib. 10. Segm. 1, &c. was an *Athenian*, had his Education in *Samos* amongſt a Colony of his Country-men ſent thither, and return'd to *Athens*, when he was about eighteen Years old, at the time that *Xenocrates* preſided over the Academy, and *Ariſtotle* had form'd a School in *Chalcis*, he at firſt philoſophiz'd in Common with others, but afterwards eſtabliſh'd a Sect apart from the reſt, and call'd it after his own Name, he began to ſtudy Philoſophy when he was no more than twelve or fourteen Years of Age, he inveigh'd againſt the *Grammarians* for not being able to explain what *Heſiod* meant by his *Chaos*, for he taught Grammar firſt, but reading the Books of *Democritus*, he turn'd his Mind to Philoſophy, from whom he is ſaid to have deriv'd all his Opinions concerning Nature; The *Stoicks* were his great Adverſaries, and handed about no leſs than fifty Epiſtles writ in a looſe and laſcivious Strain, which they affirm'd to be his, he made a Pathick of one of his Brothers, and kept *Leontium* as a Miſs, he was guilty of very baſe and ſervile Flatteries in his Epiſtles to *Lyſimachus*, giving him the Appellations of *Pæan*, and King, he practic'd the ſame mean Arts towards *Idomeneus*, *Herodotus*, and *Timocrates*, and in his Epiſtles to *Leontium* he makes uſe of the ſame Titles of *Paan*, and King, and writing to *Pythocles*, a beautiful young Man, he ſays, he will ſtay there, in Expectation of his moſt lovely and divine Preſence, nor was *Leontium* his only Miſs, for he writ to ſeveral others, and in his Book περὶ τέλους, or, *de fine*, that is concerning the *Summum Bonum*, or, the chief Good which a Man ſhould purſue, his Words are; For I truly have no Notion of what is Good, if we take away all the Pleaſures of Taſt, and the Enjoyments of Luſt, the Delicacies of Sounds and of Muſick, and the Satisfaction which ariſes from beholding Comelineſs and Beauty, οὐ γὰρ ἔγωγε ἔχω τί νοήσω τἀγαθὸν, ἀφαιρῶν μὲν τὰς διὰ χυλῶν ἡδονὰς, ἀφαιρῶν δὲ καὶ τὰς δι' ἀφροδισίων, καὶ τὰς δι' ἀκροαμάτων, καὶ τὰς διὰ μορφᾶς. *Epictetus* alſo reprehends him for his laſcivious Way of Diſcourſing, and has many very ſevere Expreſſions againſt him, not much to the Honour of his Character; *Timocrates*, the Brother of *Metrodorus*, the great Admirer of *Epicurus*, and once one of his Scholars, but left him, relates, that he us'd to vomit twice a day from his exceſſive Luxury, and that he himſelf had much ado to eſcape theſe nocturnal Cuſtoms, and theſe ſecret Conventions of Riot and Philoſophy, that *Epicurus* was very Ignorant in his Language, and his Converſation, but more ſo, as to the Conduct of Life, and the Knowledge of the World, that he was grievouſly afflicted with Diſtempers in his Body, ſo that he could not riſe from his Seat for many Years, and yet that he ſpent at the ſame Time a Mina, or above three Pounds every day in Eating and Drinking, which is alſo acknowledg'd by him in his Epiſtle to *Leontium*, and the Philoſophers of *Mitylene*; in his Epiſtles concerning *Nauſiphanes* his own Maſter, and the Scholar of *Pyrrho*, he reviles him with the Names of Lungs, or the ſenſeleſs Prater, an Illiterate, an Impoſtor, and a Whore-Maſter; he calls the Followers of *Plato* the Flatterers of *Dionyſius*, and *Plato* himſelf was, for his Pride, or his Riches, or his Politeneſs, and Elegance of Language, which *Epicurus* condemn'd, term'd the Golden; *Ariſtotle*, he ſays, was a Spendthrift, and went for a Soldier upon the conſuming of his Patrimony, and ſold Drugs for his Support, or perhaps turn'd Mountebank; *Protagoras* was a Porter, writ for *Democritus*, and became a poor Retailer of Learning in the *Trivia*, and the common Streets; *Heraclitus* was a Puzler, and a Diſturber, and Confounder of Philoſophy, without knowing any Thing certainly and clearly; *Democritus* was capable of Judging of Trifles; and *Antidorus* was a fooliſh and inſignificant Flatterer; the *Cyzicenes* were Enemies of *Greece*, and the *Logicians* were a ſet of Men full of Malice and Envy, and *Pyrrho* was one, who had neither Learning nor Education; The Hiſtorian yet tells us, that theſe were Strange and Romantick Stories forg'd of him, that there were a great many, who atteſted his Extraordinary and Incredible Candor towards all, and that the Statues of Braſs, which were erected by the *Athenians* in Honour of him, were a Proof of it; that he had ſo many Friends, that whole Cities could not contain them, that all his Diſciples were ſo fully attach't to his Doctrine, that none of them ever left him excepting *Metrodorus* of *Stratonice*, who went over to *Carneades*, and that there was a perpetual Succeſſion of Diſciples in his School, which continu'd when all Others fail'd, he had likewiſe the greateſt Regard for, and profeſs'd the utmoſt Duty to his Parents, expreſs'd the moſt intimate Love and Affection for his Brothers, and us'd all the Lenity and Mildneſs, which was poſſible towards his Servants, and to comprehend the Sum of his Character in one ſhort Deſcription, he was a Perſon of the moſt exceeding Humanity, and of an univerſal Benevolence, he was a devout Worſhipper of the Gods, whom therefore he did not deny, but only the God of *Anaxagoras*, and *Plato*, that is the Mind and Intelligence of the other Philoſophers, and an hearty and ſincere Lover of his Country, he us'd to live with his Followers and Friends in a Garden, and according to *Diocles*, upon very plain and ordinary Meats, a little Wine, and with Water for their common Drinking, he was not willing that all Things ſhould be common amongſt his Diſciples, which *Pythagoras* preſcrib'd amongſt his, becauſe he thought that ſhew'd a diſtruſt of each other, which ought to be baniſh'd all real Friendſhip, which he was deſirous to eſtabliſh amongſt thoſe who retain'd to him; As to his living upon Water, and Bread, and ſuch kind of Food, he is his own Witneſs in his Epiſtles, in which he likewiſe deſires a little Cheeſe may be ſent to him, that he may, if he has a mind to it, make a more ſumptuous Banquet, than he generally allows himſelf; of the ancient Philoſophers he had the higheſt Opinion of *Anaxagoras*, tho' he

This Paſſage Athenæus alſo makes mention of, and Tully in his Third Book of the Tuſculan Queſtions.

contradicted him in ſome Things, and of *Archelaus* the Maſter of *Socrates*; he was very ſimple and plain in his Diction and Stile, and in his Book of Oratory he adviſes that nothing elſe ſhould be regarded, but how to expreſs your ſelf with Clearneſs and Perſpicuity, and in his Epiſtles where others us'd to write χαίρειν, [tho' the Epiſtles mention'd in his Life, to *Herodotus*, *Pythocles*, and *Menœceus* do all begin with χαίρειν] he choſe the Form of εὖ πράττειν, and it was his Notion that to live Vertuouſly was the beſt Thing one cou'd do; he began to ſtudy Philoſophy when he was twelve Years old, and was at the Head of a School which he inſtituted and form'd at Thirty, he was born ſeven Years after *Plato* dy'd, he taught at *Mitylene* and *Lampſacus* for the firſt five Years, and then remov'd to *Athens*, where he continu'd to his Death, which was in his two and ſeventieth Year, and was cauſ'd by a Stone in the Bladder, from whence a Stoppage of Urine enſu'd, he labour'd under this Calamity for fourteen Days, and being worn out with Pain, he went into a hot Bath, deſir'd a draught of ſtrong Wine to be given him, adviſ'd his Followers and Friends to remember the Inſtructions, and the Precepts he had taught them, and ſo expired.

I have been more Particular in the Life of this Philoſopher, becauſe it is ſo variouſly Reported, and it is not Impoſſible, but he might be a better Man than his Enemies, and a worſe Man than his Friends, repreſented him; it is plain, however, that his Doctrines tended to Vice, and to Atheiſm; to Vice, by the Paſſage before alledg'd, and to Atheiſm, by thoſe which follow; His Doctrines Segm. 29. were comprehended in three Epiſtles, the firſt to *Herodotus*, concerning Natural Philoſophy, the ſecond to *Pythocles*, concerning the Celeſtial Bodies, or Aſtronomy, and the third to *Menœceus*, concerning Morality and the Conduct of Life, and what in it we ought to chuſe or avoid.

In that to *Herodotus* he tells us, Segm. 37. and 38. πρῶτον μὲν οὖν τὰ ὑποτεταγμένα τοῖς φθόγγοις δεῖ εἰληφέναι, &c. that the firſt Thing we are to do in Philoſophy, is to conſider, and to aſcertain, what Ideas are annext to the Words we make uſe of, ſo that our Diſputes ſhould not be about Names or Words, but about the Things expreſs'd by them. Segm. 38, 39, 40, 41, 42. 44. he tells us, ὅτι οὐδὲν γίνεται ἐκ τοῦ μὴ ὄντος, καὶ μὴν καὶ τὸ πᾶν ἀεὶ τοιοῦτον ἦν οἷον νῦν ἐστι, καὶ ἀεὶ τοιοῦτον ἔσται, οὐθὲν γάρ ἐστιν εἰς ὃ μεταβάλλει, παρὰ γὰρ τὸ πᾶν οὐθὲν ἐστὶν, εἰς ὃ ἂν εἰσελθὸν αὐτὸ τὴν μεταβολὴν ποιήσαιτο, τὸ πᾶν ἐστὶ σῶμα, καὶ εἰ μὴ ἦν ὃ κενὸν, καὶ χώραν καὶ ἀναφῆ φύσιν ὀνομάζομεν, οὐκ ἂν εἶχε τὰ σώματα ὅπου ἦν οὐδὲ δι' οὗ ἐκινεῖτο, παρὰ δὲ ταῦτα οὐθὲν οὔτε ἐπινοηθῆναι δύναται, τῶν σωμάτων τὰ μέν ἐστι συγκρίσεις, τὰ δ' ἐξ ὧν αἱ συγκρίσεις πεποίηνται, ταῦτα δέ ἐστιν ἄτομα καὶ ἀμετάβλητα, εἴπερ μὴ μέλλει πάντα εἰς τὸ μὴ ὂν Φθαρήσεσθαι, ἀλλ' ἰσχύοντα ὑπομένειν, ἐν ταῖς διαλύσεσι τῶν συγκρίσεων, πλήρη τὴν φύσιν ὄντα, καὶ οὐκ ἔχοντα ὅπῃ ἢ ὅπως διαλυθήσεται, ὥστε τὰς ἀρχὰς ἀτόμους ἀναγκαῖον εἶναι σωμάτων φύσεις, ἀλλὰ μὴν καὶ τὸ πᾶν ἄπειρόν ἐστι τῷ πλήθει τῶν σωμάτων, καὶ τῷ μεγέθει τοῦ κενοῦ, πρός τε τούτοις τὰ ἄτομα τῶν σωμάτων, καὶ μεστὰ, ἐξ ὧν καὶ αἱ συγκρίσεις γίνονται καὶ εἰς ἃ διαλύονται, ἀπερίληπτά ἐστι ταῖς διαφοραῖς τῶν σχημάτων, μηδὲ ποιότητά τινα φησὶ περὶ τὰς ἀτόμους εἶναι πλὴν σχήματος καὶ μεγέθους καὶ βάρους. Namely, that Nothing can be produc'd from what is not in Being, and that the Univerſe always was ſuch as it now is, and always will be, ſince there is not any Thing, into which it can be transform'd or chang'd, for beſides the Univerſe there is nothing, which entering into it, can cauſe ſuch Alteration or Change, this Univerſe is Corporeal or Body, and if there was not what we call Vacuum, or Space, or a Nature which is not Solid, Bodies would neither have a Place to exiſt in, nor Room to move in; of more than theſe, that is than of Space and Bodies, we can have no Apprehenſion or Notion, and of Bodies there are two Sorts, either they are Compoſitions and Concretions, or they are ſuch of which thoſe Compoſitions or Concretions are made, the latter of which are Atoms, or the leaſt Portions of Matter, of which Bodies conſiſt, which Atoms are immutable, for if they could be diſſolv'd, or chang'd, they would be diſſolv'd into nothing, which is impoſſible, ſince as ſomething cannot be produc'd out of nothing, ſo neither can it be reſolv'd into it, theſe Atoms therefore are firm, and ſtable, and full of their own Subſtance, without any Vacuity, and cannot, upon the Diſſolution of Compoſitions or Concretions, be themſelves diſſolv'd by any Force without them, or within them, ſo that the firſt Principles of all Things are theſe ſolid, conſiſtent Atoms, ſince all Things are Corporeal; moreover the Univerſe is ſaid to be infinite in the Multitude of Bodies, or of Atoms the Compounders of them, and in the largeneſs and extent of the Vacuum, theſe Atoms are likewiſe affirm'd to be incom-

Sir Iſ. Newt. Optical Query 31. towards the End. It ſeems probable to me, that God in the Beginning form'd Matter in Solid, Maſſy, Hard, and Impenetrable Particles &c.

prehenſible, and infinite in the Difference of their Figures, and to have no Quality belonging to them, excepting that of Figure, Magnitude, and Gravity.

The Principles of the foregoing Philoſophers compar'd with one another, and with thoſe of the Moderns.

§. 15. AND thus we have a ſhort Epitome of the preſent Philoſophy of a Similar Matter, and a Vacuum from the famous and renown'd *Epicurus*, and all that it has wiſely and prudently done, is to annex the Mind or Intelligence of *Anaxagoras* to that Syſteme, which diſcarded and renounc'd it, but whatever prudential Reaſons it might have for ſuch a Conduct, which are Evident, it will be proper to conſider the Philoſophy of ſuch a Procedure.

ANY one, who affirms an infinite Vacuum, and an infinite Number of Atoms unchangeable in their Nature, which were always ſuch, and always will be ſuch, by whoſe Concourſes and Concretions all Things are and were form'd, and excludes a God, or a Mind and Intelligence from the Univerſe, propoſes Things which are conſiſtent; for as Almighty God is an infinite Agent, what Exertion of Power or Action is there in an infinite Vacuum? An infinite Space without any Thing in it entirely deſtroys an infinite Agency, but is well enough ſuited for the Rambling of Atoms about in it in order to form their own Productions; Beſides, what Influence can there be ſuppos'd from Almighty God, or an infinite Mind, or Intelligence, in the making or conſtituting of ſolid Atoms of Matter, which always were and ever will be the ſame? They are Principles of Nature independent of any Creating Power, and therefore it is abſurd to annex an Infinite and Superintending Being to ſuch a Syſteme.

Pherecydes, *Thales*, *Anaximenes*, *Anaximander*, *Anaxagoras*, *Plato*, *Ariſtotle*, *Zeno*, and *Pythagoras* on the Contrary, who affirm'd a Plenum, might juſtly and conſiſtently affirm a God, a Mind, and an infinite Intelligence, from whom all that Plenitude and Fullneſs of Being was deriv'd, who actuated and inform'd the Whole, and diverſify'd the τὸ πᾶν according to his own Will and Pleaſure, without being oblig'd to a neceſſary and infinite Vacuum, and an infinite Number of neceſſary and ſolid Atoms to be the Inſtruments of his Productions, which are nothing more than the Machinery of the Philoſophers. To take therefore the Mind or Intelligence of the one Sect of Philoſophers, and the Vacuum and Atoms of the other, is a great want of Underſtanding in the Principles of the ancient Philoſophy, and ſhews no leſs an Ignorance in the Nature of Things.

WHAT Side the beſt and wiſeſt *Romans* took in this Controverſy of the Philoſophers concerning *Anaxagoras*, and *Plato*'s, and *Zeno*'s Scheme of the Univerſe, and *Democritus*, and *Epicurus*'s is not unknown; *Cato*, and *Tully*, and *Brutus*, and all the ſober Part of *Rome*, and the Patrons of the Commonwealth, and of the ancient Conſtitution amongſt them, eſpous'd the former, and *Catiline*, *Cæſar*, and *Anthony*, and the Followers of them, the Licentious and Vicious, the Advancers of Tyranny and Arbitrary Power, and the Over-turners of that celebrated and noble Polity, contended for the latter.

Concerning Ocellus Lucanus *and* Sanchoniathos

§. 16. *Ocellus Lucanus*, who is affirm'd to have been Contemporary with *Moſes*, ſays thus, ἀγένητον τὸ πᾶν καὶ ἀνώλεθρον, ἄναρχον καὶ ἀτελεύτητον, ἀεὶ ὄντος τοῦ κόσμου ἀναγκαῖον καὶ τὰ μέρη αὐτοῦ συνυπάρχειν, τὸ ἀεὶ κίνητον θεῖον μὲν καὶ λόγον ἔχον καὶ ἔμφρον, συνέχει τὸν κόσμον ἁρμονία, ταύτης δ' αἴτιος ὁ Θεός, from whence it is manifeſt, that he with *Anaxagoras*, and *Plato*, affirm'd an Eternity and Infinity of the World, and therefore that there was a Plenum in it, but that it was animated and rais'd into an Energy by the infinite Mind and Intelligence, who was the Author of the Beauty, Order, and Harmony we obſerve thro' the whole Expanſe of Nature.

Sanchoniathos in his Collections of the moſt ancient Hiſtories of the *Phœnicians*, and who himſelf was a *Phœnician*, the Prieſt of *Belus* or *Baal*, and not much later than *Moſes*, according to *Philo Byblius*'s Verſion of him, has this Account of the World's Origine. Φοινίκων θεολογία τὴν τῶν ὅλων ἀρχὴν ὑποτίθεται ἀέρα ζοφώδη καὶ πνευματώδη, ἢ πνοὴν ἀέρος ζοφώδους, καὶ χάος θολερὸν ἐρεβῶδες, ταῦτα δὲ εἶναι ἄπειρα, καὶ διὰ πολὺν αἰῶνα μὴ ἔχειν πέρας, ὅτε δέ, φασίν, ἠράσθη τὸ πνεῦμα τῶν ἰδίων ἀρχῶν, καὶ ἐγένετο σύγκρασις, ἡ πλοκὴ ἐκείνη ἐκλήθη πόθος, αὕτη δὲ ἀρχὴ κτίσεως ἁπάντων, αὐτὸ δὲ οὐκ ἐγίνωσκε τὴν αὐτοῦ κτίσιν, καὶ ἐκ τῆς αὐτοῦ συμπλοκῆς τοῦ πνεύματος ἐγένετο Μώτ, τοῦτο τινές φασιν ἰλύν, οἱ δὲ ὑδατώδους μίξεως σῆψιν καὶ ἐκ ταύτης ἐγένετο πᾶσα σπορὰ κτίσεως καὶ γένεσις τῶν ὅλων. That is, the *Phœnician* Theology ſuppos'd a dark and ſpirituous and active Air, or the breathing or blaſt of a dark Air, and a tumultuous and dark Chaos, to be the Principle and

Origine of all Things, and that theſe were Infinite, and for a long Tract of Time without Bounds or Limits, but when the Wind or Spirit was in Love with it's own Principles, and a Mixture of the one with the other enſu'd, this Union and Conjunction of them was call'd, Appetite, or Inclination, by which Bodies became endu'd with certain Propenſities, which was the Principle of the Formation of all Things, but the Spirit it ſelf knew no Cauſe of it's Production; from the Concourſe of this Spirit with, and it's Influences upon the *Chaos*, Μῶτ or the ἰλὺς or Mud, or a Mixture of Water and Earth aroſe, from whence were deriv'd the Seeds of every created Being, and of all Things whatſoever.

In which Account we have evidently contain'd an infinite and paſſive Subſtance, and of a *Chaos*, which fill'd the Univerſe, or of a Plenum and of an active and intelligent Principle, which diſpos'd every Thing into the Order we now ſee, which was Self-exiſtent and Eternal.

Concerning Moſes *and* Juſtin Martyr *and the Chriſtian Philoſophy.*

§. 17. And this ſo exactly Correſponds with what *Moſes* relates in the ſacred Writings, of God's creating the Heaven and the Earth, of the Earth's being without Form, and Void, and of Darkneſs being upon the Face of the Deep, and of the Spirit of God moving upon the Face of the Waters, and his dividing Light from Darkneſs, and ſeparating the Waters, Earth, Sun, Moon, and Stars to their ſeveral Places, his Creating Animals, and the Herbs of the Field, that we may juſtly think and imagine *Sanchoniatho's*, and the *Phœnician* Philoſophy was deduc'd from that of *Moſes*, and conſequently that the Moſaick do's ſuppoſe an univerſal Plenum, or *Chaos* actuated and influenc'd into Order by the Energy and Influence of the divine Intelligence, eſpecially ſince Waters, and Darkneſs, and the Deep, are all affirm'd by him to exiſt before this Creation, and therefore we may reaſonably conclude that the moſt ancient and current Philoſophy amongſt the *Ægyptians* likewiſe, in whoſe Learning *Moſes* was ſo particularly converſant, was in the ſame Strain, as well as that all the Eaſtern Nations, that *Abraham*, and *Melchiſedec*, or *Sem*, and conſequently that the Antediluvian Patriarchs taught the ſame Doctrine till we come to *Adam* himſelf; and this is the more probable ſince *Pherecydes*, who was a *Syrian*, or *Phœnician*, *Thales*, *Anaxagoras*, *Plato*, and *Pythagoras*, ſome of whom travel'd into *Ægypt*, ſtill brought from thence the ſame Opinions of the World's Production, and conſtantly propos'd an infinite Plenum of undigeſted Matter, and an infinite Mind or Intelligence, which acted upon it for their Principles of all Things, till *Democritus*, and *Epicurus* firſt invented their Neceſſary and Self-exiſtent Vacuum, and Atoms, and the Gravity of them, without any wiſe or intelligent Cauſe to direct or guide them; and for the ſame Reaſon, I do not doubt, but the Aſtronomy of *Thales*, *Anaxagoras*, and *Pythagoras*, which is now the *Copernican*, was profeſs'd by the Antediluvians up to our firſt Parents, and the beginning of the World.

And as to the Chriſtian Philoſophy, we find *Juſtin Martyr* in his firſt Apology for the Chriſtians propoſing their Sentiments concerning Nature exactly conformable to thoſe which *Moſes* had taught, ϗ πάντα τὴν ἀρχὴν ἀγαθὸν ὄντα δημιȣργῆσαι αὐτὸν ἐξ ἀμόρφȣ ὕλης δι' ἀνθρώπȣς δεδιδάγμεθα.

Another way of defending a Vacuum, and the Confutation of it. Dr. Keill Introduct. ad Veram Phyſ. Lect. 5. Edit. 3.

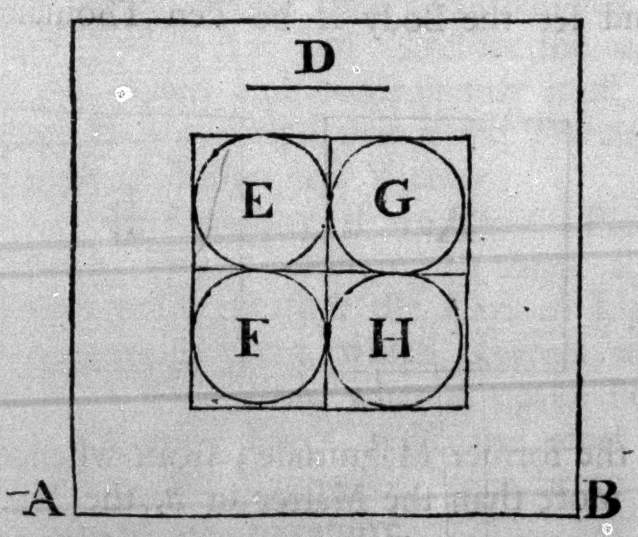
§. 18. Notwithstanding Matters ſtand thus in Relation to a Plenum and a Vacuum, that all the moſt ancient and celebrated Philoſophers aſſert the firſt, and reject the laſt, yet the preſent Philoſophy is ſo fond of the latter, that it has contriv'd another Solution of the Difficulty before-mention'd, which lies againſt a Vacuum, that in an exceeding rare Medium as the Air, there muſt be ſo much Vacuity, whilſt we affirm Matter to be Similar, that it wou'd be as impoſſible for us to breath in it, as in an exhauſted Receiver, Water likewiſe might be compreſs'd, *&c.*

In order to evade this ſort of Arguments, it is endeavour'd by the obtaining Philoſophy to attenuate and ſubtilize Matter as far as poſſible, when it do's not at the ſame time conſider, that, let us diminiſh the Parts of a Similar Matter as much, and as Infinitely as we pleaſe, all thoſe Parts will take up no more Space than the Whole out of which they were divided.

Thus it is premis'd by way of Lemma, that any Quantity of Matter being given, out of it, or any Part of it may be form'd a Concave Sphere, whoſe Semidiameter is equal to a right Line given. Let the Particle of Matter be a^3, and the right Line given b, let the Ratio of the Periphery of the Circle be to the Radius as p to r, let the Semidiameter of the Concavity be x, and the Thickneſs of the ſmall ſkin encompaſſing the Concavity of the Sphere will be $b-x$, and the Cylinder circumſcrib'd to the Sphere, whoſe Radius is b, will be $\frac{p\times b^3}{r}$, from whence the Sphere inſcrib'd in the Cylinder will be $\frac{2\times pb^3}{3r}$, and by the ſame Reaſoning the Sphere, whoſe Radius is x, will be $\frac{2\times px^3}{3r}$, and the Difference of theſe two Spheres, namely $\frac{2p}{3r}\times b^3-x^3$ will be equal to the Spherical Lamella or to the Particle of Matter given a^3, that is, $\frac{2p}{3r}\times b^3-x^3=a^3$, and by the common Reduction of Equations $b^3-x^3=\frac{3ra^3}{2p}$ and $x^3=b^3-\frac{3ra^3}{2p}$ and $x=\sqrt{3.\,b^3-\frac{3ra^3}{2p}}$, and conſequently the Thickneſs of the Spherical Lamella or $b-x$ will be $=b-\sqrt{3.\,b^3-\frac{3ra^3}{2p}}$.

AND by the ſame Method of arguing from a given Quantity of Matter concave Cubes, and concave Cylinders, or Bodies of any other concave Figure may be form'd, whoſe Sides are equal to a right Line given; 'Tis very well, therefore according to this Demonſtration, the ſmalleſt Particle of Matter may be form'd into the largeſt Cube, or Sphere, or Cylinder, whoſe Concavity may be infinitely great, and the Thickneſs of the Lamella which encompaſſes it infinitely ſmall, it is own'd and acknowledg'd, but will it from thence follow that Space is more fill'd than before? Will not there be ſtill the ſame Proportion betwixt Matter and Vacuum, as there was? And can it be imagin'd that a Matter blown up into the Bubbles of a School-Boy cannot be compreſs'd? Water is not in it ſelf compreſſible or very little, nor even Air to any extraordinary Degree, but if either the one or the other conſiſted of ſuch Globes, whoſe Concavity was great, and the Film which encompaſs'd it infinitely ſmall, wou'd they not be more eaſily broken and diſſolv'd by the extreme Force of Screws, and other Violences us'd to deſtroy their Dimenſions, than the Bubbles we nam'd by the Force of the Air? There is nothing can be more certain.

HOWEVER, this Philoſophy goes on to tell us, in it's firſt Theorem conſequent upon the preceding Lemma, that any Quantity of Matter, however ſmall being given, and any Space which is finite, however large, being alſo given, which Space for Inſtance, is ſuppos'd to be a Cube circumſcrib'd to the Sphere of Saturn, it is poſſible that ſuch a little Grain of Matter ſhould be diffus'd thro' all that Space, and ſhou'd fill it ſo, that there ſhould be no Pore or Vacuity in it, whoſe Diameter ſhould exceed a right Line given, that is, it is propos'd to prove that the leaſt Particle of Matter may fill the greateſt Space without any ſenſible Interſtices in ſuch a Repletion. Let the given Space be a Cube, whoſe ſide is AB equal to the Diameter of *Saturn*'s Orbit, let the Particle of Matter given be b^3, and the Diameter of the Pores D, which is in the preſent Caſe ſuppos'd exceeding ſmall; Let AB be imagin'd to be divided into Parts equal to the right Line D, whoſe Number therefore will be Finite, ſince neither AB is ſuppos'd to be infinitely great, not yet D infinitely ſmall, let that Number be n, and conſequently, $nD=AB$ and $n^3D^3=\overline{AB}|^3$; Let us now conceive the given Space to be divided into Cubes, the ſides of each of which are equal to D, and the Number of the Cubes will be n^3, and let theſe Cubes be expreſs'd by E, F, G, H in the Figure; Farther, let the Particle of Matter b^3 be conceiv'd to be divided into Parts, whoſe Number is n^3 and in every Cubical Space, let one of theſe Parts be placed, by which means the Particle of Matter b^3 will be diffus'd into all that Space, every Particle likewiſe of b^3 being diſpos'd into the little Cell belonging



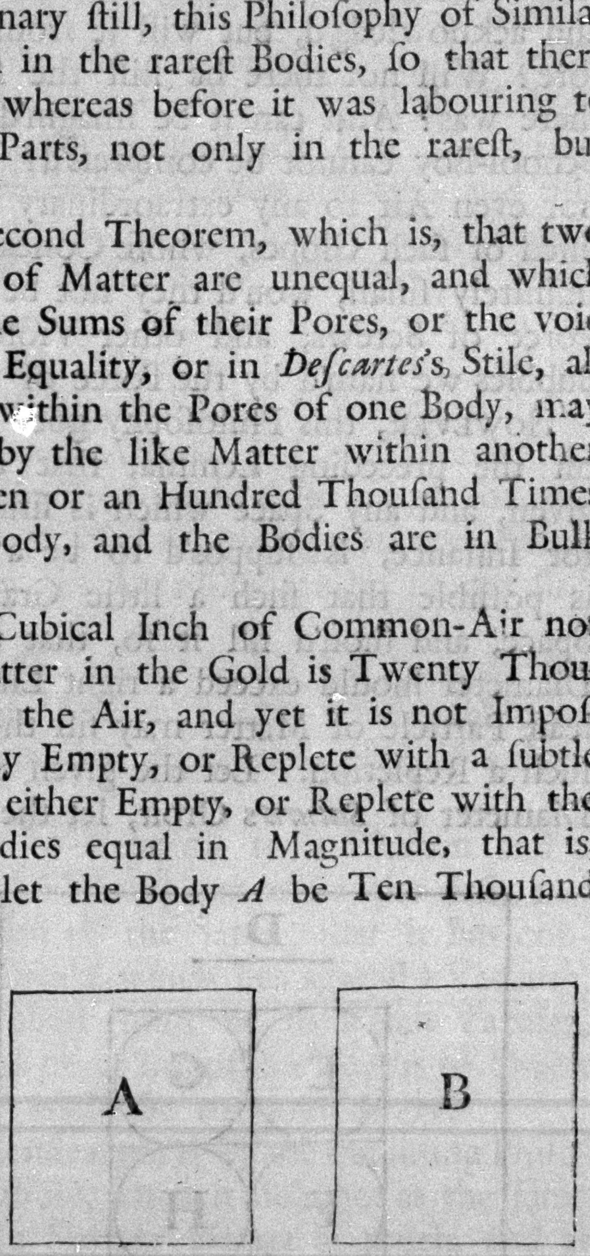
to it, may be form'd into a concave Sphere, whoſe Diameter is equal to the right Line given *D*, from whence it will come to paſs, that every Sphere will touch that which is next it, and a given Particle of Matter, however ſmall, as b^3, will fill a Space given however large, ſo that there ſhall be no Pore in it, whoſe Diameter ſhall exceed the right Line *D*, which is ſuppos'd extremly, tho' not infinitely ſmall.

To which we again anſwer, that ſuppoſing the Particle of Matter, whilſt we conſider it as Similar, is b^3 or 1, and imagining the Space to be $\overline{AB}|^3$ or 10 Millions of Millions of Millions *&c.* and let the Number of Cubes of this Space be n^3, and the Number of Parts into which b^3 is divided be alſo n^3, we ſay every Part of the Particle of Matter b^3 will be to every Part of Space $\overline{AB}|^3$, as 1 to 10 Millions of Millions of Millions, *&c.* and conſequently every Particle of Matter, if form'd into a Sphere, wou'd either ſurround, or be ſurrounded, by 10 Millions of Millions of Millons, *&c.* of Space, agreeable to what we have affirm'd in our *Principles of Natural Philoſophy*, Chap. 7. §. 8. Part 1. againſt which this Theorem ſeems to be level'd, This therefore cannot but be an odd way of filling Space with Matter, which leaves it to be compreſs'd by the ſmalleſt Force into a 10 Millionth of Millonth of Millionth, *&c.* of the Dimenſions into which this Philoſophy endeavours to extend it.

BESIDES, it is ſomething Marvellous and Strange, that it ſhould endeavour with ſuch Labour and Pains to ſubtilize Matter into a Plenum, which it is ſo unwilling to own, and can be no otherwiſe accounted for excepting it's being Conſcious, that a kind of Plenum, or what was approaching to it, was neceſſary in Nature, both for the Explanation of the ſmall Compreſſion of Water or Air, and of the way by which we live and breath: And what is more extraordinary ſtill, this Philoſophy of Similar Matter is here filling up all the Interſtices it can in the rareſt Bodies, ſo that there ſhould be no Vacuum, or a very inſenſible one, whereas before it was labouring to prove, that there was more Vacuum than ſolid Parts, not only in the rareſt, but even in the groſſeſt and denſeſt.

NOTWITHSTANDING which, it proceeds to a ſecond Theorem, which is, that two Bodies may be equal in Bulk, whoſe Quantities of Matter are unequal, and which obtain a given Reaſon to each other, and yet the Sums of their Pores, or the void Spaces betwixt them come near to a Reaſon of Equality, or in *Deſcartes's* Stile, all the Space which is poſſeſt by the ſubtle Matter, within the Pores of one Body, may be almoſt equal to the Space which is poſſeſs'd by the like Matter within another Body, altho' the proper Matter of one Body is Ten or an Hundred Thouſand Times more than the proper Matter of the other Body, and the Bodies are in Bulk equal.

For example, a Cubical Inch of Gold, and a Cubical Inch of Common-Air not condens'd; 'Tis certain, that the Quantity of Matter in the Gold is Twenty Thouſand Times more than the Quantity of Matter in the Air, and yet it is not Impoſſible, that the Spaces in the Gold, either abſolutely Empty, or Replete with a ſubtle Matter, may be equal to the Spaces in the Air, either Empty, or Replete with the ſame ſubtle Matter. Let *A* and *B* be two Bodies equal in Magnitude, that is, let each of them be a Cube of one Inch, and let the Body *A* be Ten Thouſand Times heavier than the Body *B*, and conſequently, include Ten Thouſand Times more Matter; Let us now ſuppoſe the Quantity of Matter in *A* to be reduc'd into a Space abſolutely full, which let it be the Hundred Thouſandth Part of a Cubical Inch, for that may be done by the Corollary of the preceding Theorem, which is, that a Body may be given, whoſe Matter, if reduc'd to an abſolute Plenum, that Plenum may be any Part given of the former Magnitude; from whence, ſince the Matter in *A* is Ten Thouſand Times more than the Matter in *B*, the Matter in *B*, if compreſs'd into an abſolute Plenum, will poſſeſs only $\frac{1}{1000000000}$, or one Ten Thouſandth Hundred Thouſandth Part of a Cubical Inch, and therefore the remaining 999999999 Parts will be either abſolute Vacuum, or Space replete with ſubtle Matter; farther, ſince the Quantity of Matter in *A* fills only the Hundred Thouſandth



ſandth Part of an Inch, the remaining 99999 Hundred Thouſandth Parts will be either abſolute Vacuum, or Space replete with the ſame ſubtle Matter, that is, by reducing the Fraction to the Denomination of the former, the void Spaces in *A* will be 999990000, Ten Thouſand Hundred Thouſandth Parts, and conſequently, the Vacuities in *A* will be to the Vacuities in *B*, as 999990000 to 999999999, or nearly in a Reaſon of Equality; But this whole Reaſoning depends upon the Corollary of the preceding Theorem, that a Body may be given, whoſe Matter, if reduc'd to an abſolute Plenum, that Plenum may be any Part given of the former Magnitude, for if ſo, there is no Queſtion we may make Choice of ſuch a Part, which ſhall leave juſt as much Vacuity, in one Body as the other, and in a Cubical Inch of Gold, as in a Cubical Inch of Common-Air; If therefore this Corollary is not true, nor the Theorem from whence it is deduc'd, which we have ſhewn, the preſent Theorem, and the Demonſtration of it will be alike Inconcluſive.

Besides which, let us conſider the very abſurdity of the Propoſition, which is endeavour'd to be prov'd, that tho' there are Twenty Thouſand more Parts of Matter in a Cubical Inch of Gold, than in a Cubical Inch of Common-Air, yet there are as many Vacuities in the one as in the other, ſuppoſing then, there are 20000 Parts of Matter, and 1 of Vacuity in Gold, there will be 1 of Matter, and 20000 of Vacuity in Common-Air, and yet by the Strength and Force of the foregoing Mathematicks, either 20000 Vacuities are prov'd equal to 1, or Matter is transform'd into Space, and Space into Matter, which is a Faculty hitherto unknown to that Science, and ſeems to explain an Artifice and Sophiſtry which is unworthy of it.

As to what is ſaid farther in this Place, that all Bodies are exceeding Rare, and that they contain very little Matter in Proportion to their Bulks, and that this is manifeſt from Diaphanous Bodies, and the Tranſmiſſion of the Rays of Light thro' Glaſs or Water as well as Air every way in right Lines, and therefore that there are Rectilineal Pores in all Directions thro' thoſe Bodies, by which the Light paſſes, and that this wou'd be impoſſible, if the Matter of the Diaphanous or Tranſparent Body was not inconſiderable in Reſpect of it's Bulk, which perhaps may be no more than a Grain of Sand to the whole Earth, and that therefore Gold, which is eight Times denſer than Glaſs, bears a very ſmall Proportion of it's Matter to it's Bulk, and that upon this infinite Porouſneſs of Bodies the Magnetick Effluvia may be accounted for in their Paſſing as eaſily thro' denſe Gold as the thinneſt Air; all theſe are Notions equally abſurd with the foregoing Demonſtrations, and are deriv'd from, and connected with them, they proceed from a great Inclination which this Philoſophy has to a Similar Matter, to Pores, and a Vacuum, and which Propenſity to them makes it aſſert very manifeſt and palpable Contradictions; Thus, beſides what we have before expreſs'd, Glaſs and Water are heavier than Air, and therefore, according to this Philoſophy, has more Matter in an equal Bulk of them, and yet they are equally Porous, becauſe they equally tranſmit the Rays of Light, that is, they have more Matter and leſs Vacuities, and they have more Matter and equal Vacuities, which is in Terms a Contradiction; ſo likewſe Gold is eight Times denſer than Glaſs, and Twenty Thouſand Times denſer than Common-Air, and yet the Magnetick Effluvia paſs as eaſily thro' Gold as Air, and therefore the one, according to this Doctrine, muſt be as Porous as the other, and conſequently muſt have as little Matter, and as much Vacuity, when it is confeſs'd that it has Twenty Thouſand Times more Matter, and Twenty Thouſand Times leſs Vacuity.

On the Contrary if we allow a Plenum, and a diſſimilar Matter, with various and differing Forces belonging to them, all theſe Difficulties are eaſily ſolv'd, Diaphanous Bodies eaſily tranſmit the Rays of Light, becauſe they have an expanſive Force appertaining to them, which concurs with the Expanſive of Light, and permits a Liberty to it's Action, whereas opake Bodies being endu'd with a greater Contractive than expanſive Force, reſiſt and repel the Rays which are Incident on them, Gold admits of the Magnetick Force being of a Contractive Nature, but repels it, when heated, by the Expanſive.

This Philoſophy yet thinks, from this infinite and imaginary Porouſneſs of Bodies, and from the vaſt Celerity of Light, it can give an Account, why the Rays of Light proceeding from ſeveral Objects, and tranſmitted thro' a ſmall Foramen, do not hinder each other's Progreſs but preſerve their Motion in a direct Line, which is ſaid cannot be explain'd by an Impulſe upon a fluid Plenum, ſince any Body, as a Plenum, having Impreſſions made upon it by ſeveral Forces in different Directions, receives and admitts of one certain and determinate Direction only, compounded and made up of all of them.

THERE are therefore two Things here to be conſider'd, the Velocity of Light, and the Tranſmiſſion of it thro' the Foramen in different Directions.

As to the Velocity of Light this Philoſophy ſeems to entertain a wrong Opinion of it, whilſt it makes it to come from the Sun to us in ſeven or eight Minutes of Time, by an actual Motion of Particles of Matter emitted from thence, and which I think has been in another Place conſider'd, what I ſhall here ſay is, that if the Emiſſions of Particles from the Sun are according to what this Philoſophy repreſents, or thoſe of Light from a Lamp or a Candle, thoſe luminous Particles muſt fill all the Space round them, which is Incredible, and the Aſſertion of ſuch a Doctrine is only owing to the Imagination, that one Particle of Similar and Homogeneous Matter may fill Ten Millions of Space, which is Impoſſible and Inconceiveable as we have already ſhewn.

AND yet again, if we will but acknowledge that Matter is Diſſimilar, and that all the World is full of it, and that Diſſimilar Matter has Diſſimilar Forces, the Propagations of Light from the Sun, from a Lamp, or a Candle, is readily ſolv'd, by the expanſive Force of the Sun, of a Lamp, or a Candle, diffuſing it's Action, and not emitting it's Particles thro' the ambient Medium, which receives their Impreſſions, not barely from a Communication of them, but as the Medium has an expanſive Force agreeable to the Expanſive impreſs'd, which it Promotes and Advances.

As to the next Thing, that the Tranſmiſſion of Light thro' the Foramen in different Directions is eaſily accounted for by the Rectilineal Pores every way, but not by bare Impulſes of Light upon a Plenum for the Reaſon above-mention'd, we anſwer.

FIRST, To ſuppoſe the Rays of Light tranſmitted every way thro' Rectilineal Pores, is to require us to imagine a very hard Thing, namely, that the Diaphanous Body, whether Glaſs or Air, is Omniporous, or which is the ſame, that it conſiſts altogether of Pores, or Vacuity, for in that infinite Croſſing of Pores at all the minuteſt Angles, which is here preſum'd, there muſt be of neceſſity a Deſtruction of all Matter in the Body, and nothing left but mere Space and Vacuum, and conſequently, the Diaphanous Body will not only be depriv'd of it's Solidity, but even of the Configuration of it's Pores too, by being reſolv'd into one continu'd Vacuity, and this Solution will meet with the Difficulty it objects to the other, ſince the Actions of Light by this means will be blended together, which the Pores were to ſeparate, and conſequently compound an Action of them all united into one.

SECOND, Granting theſe Rectilineal Pores tranſverſe to each other in an infinite Number of Angles, and the Rays of Light to paſs thro' them, wou'd not theſe Rays meet and interfere with each other in a Thouſand different Directions, and would not ſuch mutual Occourſes and Impactions of them as much interrupt and hinder their Progreſs in Directum, as if they were to meet each other in the Foramen, without ſuch Rectilineal Pores to defend and aſſiſt their Progreſſion?

THIRD, But what is more in this Doctrine, it is preſum'd, that the Action of Bodies, as the Rays of Light, is beſt promoted by contriving Pores and Vacuities for them, and the ſame is affirm'd in reſpect of the Magnetick Force, and therefore Vacuities are aſſign'd for it's paſſing thro' Gold; whereas it is wonderful that we ſhould want Vacuities and Pores here for the Propagation of the Action of Light, when to propagate the Action of other Bodies, Bodies not Vacuities are requir'd; Thus Fire and Flame is not propagated in Vacuum, but in Bodies, which are inflameable, Motion is not communicated to Vacuum but to Bodies, which are moveable, the Action of Sound is not propagated thro' Vacuum, but thro' Bodies which are Springy and Elaſtick, and why therefore ſhou'd we not think that Light is not promoted thro' Pores and Vacuum, but thro' Bodies which partake of the Nature of Light, as Diaphanous or Tranſparent Bodies, that is, which have, as Light, an expanſive Force appertaining to them?

ON the other hand, there is no Difficulty in apprehending, how a Medium, as Air or Glaſs, ſhould tranſmit an Action, as that of Light, in the ſame Direction, in which it is impreſs'd, without a Compoſition of thoſe different Forces into one, ſince that Medium, whatever it is, is equally balanc'd in it's Action of it's Parts one amongſt another, if therefore a foreign Action, as that of Light, invades it in one Direction, it muſt ſubmit to that Action, that is, there muſt be a Preponderancy, if we may call it ſo, that way, and if a Second, or a Third, or Fourth, *&c.* Aſſaults it in different Directions, it muſt likewiſe ſubmit to thoſe Actions, and in thoſe Directions and accordingly tranſmit them, ſince it holds it ſelf indifferently to all, and therefore muſt tranſmit them all in the ſame Directions, in which they are incident, allowing ſtill for the Difference of Action in Light, and in the Body, thro' which it is tranſmitted, and from whence the Refractions of it ariſe; and the ſame may be ſaid of the Magnetick Force, and of Gold, or any other Body thro' which it paſſes.

Having therefore now ſaid what we intended concerning a Vacuum, we ſhall proceed to inquire into ſome farther Arguments made uſe of for a Similar Matter and Pores, which we did not conſider in our Principles of Natural Philoſophy.

§. 19. It is ſaid in Axioms, the *14th*, *15th*, and *16th*, that Matter is every where of the ſame Nature, and has the ſame Eſſential Attributes, whether in the Heavens or in the Earth, whether it appears under the Form of a Fluid, Hard, or any other Body; that is, the Matter of any Body, of Wood for Example, do's not Eſſentially differ from the Matter of Iron, or a Stone, but that the different Forms and Appearances of Bodies are only different Modifications of the ſame Matter, and ariſe from the Various Magnitude, Figure, Texture, Situation, *&c.* of the Particles, which compoſe thoſe Bodies, and that the Qualities, or Actions, or Powers of any Bodies upon others, depend only upon the foregoing Modifications of Matter in Conjunction with the Motion of ſuch Particles.

Another way of Defending a Similar Matter, and Pores, and a Confutation of it, with a Propoſal of the Doctrine of the Expanſive and Contractive Forces.

Dr. Keill Introd. ad Ver. Phyſic. Lect. 8.

These are call'd Axioms or Self-evident Principles in Philoſophy, which yet with me are ſo far from being Self-evident, that I think the contrary to all this is manifeſt and certain, that Matter is not Homogeneous in it's own Nature, and that it's apparent Difference do's not ariſe from the Difference of the Situation, Figure, and Magnitude of it's Parts, and that it's Powers and Qualities are not deriv'd from them in Conjunction with Motion, but from the peculiar Expanſive and Contractive Forces of it; by an Expanſive Force I mean, that which tends from a Centre of Action, and by a Contractive, that which tends towards one.

Notwithstanding which Axioms or Self-evident Principles of Philoſophy, it thinks good to prove the Truth of them, and from that Endeavour ſhews, that thoſe Principles are not Self-evident ones.

But how is this endeavour'd? It is by giving us an Hiſtory of the Tranſmutation of Sea-Water into Clouds and Vapours, from thence into Rain, after that into Plants and Trees, according to the Nature of the different Seeds, in which it Lodges, which alſo conſiſt of Various and Heterogeneous Parts, as the Root, Stalk, Fibres, Flowers, *&c.* for Inſtance, let us take Flax or Hemp, this beaten or pounded is ſpun into Thread, then wove into Cloth, the Shreds of which ſteep't in Water, reduc'd to a Pulp by wooden Peſtles, and ſpread upon Wires and dry'd, is what we call Paper, this thrown into the Fire vaniſhes into Smoke and Aſhes, all which Phænomenons are affirm'd to proceed from a Change in the Texture, Situation, Figure, and Magnitude of the Parts of Sea-Water. Thus Metals are fus'd by the force of Fire, and by a change of Situation in the Parts are diſſolv'd from their Coheſion into a Fluid Subſtance. The Diſſolution of Salts and Metals in their proper Menſtruums ariſes from a Separation of Parts by Fermentation, and from a Diviſion of them into the leaſt Atoms, and an Agitation of them by Motion, from whence they become Fluid; and from the Figures and the other Modifications of the Parts of Bodies, diverſe Qualities, which are peculiar to them, are caus'd, which are deſtroy'd, if that Conſtitution of Parts is alter'd.

In like Manner from the ſame Matter, that is, Iron, Keys, Knives, Files, Saws, and an hundred other Inſtruments are made, whoſe Qualities depend only upon their Figures: Keys have the power of a Lever to remove the Obſtacle, and Knives of a Wedge to ſeparate the Parts of Matter to which they are apply'd, and it is prov'd by the Writers in Mechanicks, that their Moment or Force is owing to their make: Clocks derive their Powers and Motions from their Wheels, and the Machines, which produce ſuch ſtupendous Effects we Experience, obtain thoſe Faculties from their Compoſition and Fabrick: The Roughneſs in the Surfaces of Bodies is the occaſion of Light's being reflected every way in various and different Angles, and conſequently it's Reflection is owing to the Configuration of the Parts of ſuch Bodies, this is confirm'd from Ice or Glaſs, which when whole, and ſmooth, and poliſh'd, is not endu'd with any Colour, but when Ground and broken into Pieces, and by that means acquiring a rough and angular Surface, appears White, and it is the ſame in Water when work'd and fermented into a Froth.

In order to juſtify this Philoſophy of Similar Matter ſtill farther, Sir *Iſaac Newton's* Doctrine of Light and Colours is alledg'd, of which we ſhall ſay no more here, and even Opticks and the Phænomenons from Plane, Concave, and Convex Speculums are introduc'd to prove the Truth of the Corpuſcular Syſteme, which are all ſaid to proceed from a Change of Diſtance or Situation.

THE Earth is revolv'd about the Sun with it's Axis inclin'd to the plane of the Ecliptick in an Angle of 66½ Degrees, but always carry'd Parallel to it ſelf, from whence in it's Period, firſt one of it's Poles is obverted to the Sun, and then another, by which all the different Seaſons of the Year are occaſion'd, and the various Productions of them, which are only effects conſequent upon a Change of Situation; What therefore may not Situation, Diſtance, Magnitude, Figure, and the Structure of Parts, and the infinite Combinations of all theſe perform join'd with the Motion and Subtlety of Effluviums? The magnetick Attractions are owing to the Structure of the Parts, for if the Magnet receives a good ſtrong Blow from an Hammer, it changes it's Poles, and if thrown into the Fire, looſes it's Vertue, which muſt be from an Alteration in the Conſtitution and Poſition of the internal Parts, but how and in what Manner the Magnet operates is a myſtery not yet explain'd by Philoſophers, tho' endeavour'd by ſeveral; This is a ſhort Account of this new Defence of a Similar and Homogeneous Matter.

FIRST, As to Sea-Water being transform'd into Clouds and Vapours by rarefying the Matter and enlargeing the Pores, that is much better accounted for by the expanſive Force of the Sun changing the Action of the Sea-Water, by which from a Salt, Heavy, and Contractive Body, it becomes a Sweet, Volatile, Light, and Expanſive one, afterwards by the contractive Force of Cold theſe Clouds and Vapours coagulate into Rain, and fall in Showers, or into Snow and Hail and deſcend in that Form, which is not done by altering the Poſition of the Parts, but changing the intrinſick Force of them, namely, from an Expanſive into various Degrees of the Contractive; Rain moiſtening the Seeds of the Earth, and thereby exerciſing a kind of expanſive Force upon the ſolid Matrixes which receive it, and the Sun afterwards ſupervening with a ſtronger and more vigorous Expanſive, Vegetation is cauſ'd, and the Seeds, thus impregnated with the Expanſive of the Sun and the Rain, ſhoot forth into Plants and Trees, which do's not proceed from an Alteration of the Figure and Texture of the Parts, for that is only conſequent, but from new Forces impreſs'd and induc'd upon them, by which from a contractive Nature they riſe into a Degree of the Expanſive from the Rain and Sun; The Parts of Plants and Trees are Root, Stalk, Fibres, and Flowers, that is, more or leſs Solid, as they have a greater or leſs Proportion of the Contractive, and a leſs or greater of the Expanſive; amongſt the Plants, becauſe it admits of moſt Variations, let us, as in the Inſtance before, take Flax or Hemp, which when beaten or pounded, that is, from an Expanſive Force it becomes diſſipated and diffuſ'd into a ſilky and pliant Subſtance, by a Contractive of the Fingers it is ſpun into Thread, and wove into a cloſe Contexture by that of the Loom, it is by the Expanſive Force reduc'd into Shreds and a Pulp, and then from the Contractive of the Air, and from the Diſſipation of the Expanſive of Water, which is equal to a Contractive, cemented into Paper, and laſtly by the Expanſive of Fire it is diſſolv'd into Smoke, and a Light, and Volatile Aſhes, from whence it is apparent, that theſe different Effects are produc'd from different Forces, and that the Effects, which are produc'd, conſtantly partake of the Nature of the Forces, which produce them, and that the Alterations of the Poſition of Parts are not the Cauſes of theſe Effects, nor are the Effects themſelves, but the Forces acting are the Cauſes, and the Forces impreſs'd are the Effects, and the Changes of Situation in the Parts of theſe Bodies do only follow, and are conſequent upon ſuch Effects, and ſuch Actions producing them.

The Fuſion of Metals is the next Example, which this Philoſophy alledges to prove the different Situation of Parts is the cauſe of the different Forms of Bodies, which is an Argument for the Doctrine we have advanc'd of the Expanſive and Contractive Forces, for Metals are Solid, and have their Coheſion from the Contractive Force in them, and they become Fluid by the Expanſive Force of Fire, which if in an equal Balance with the Contractive, the Parts of the fluid Metal are Quieſcent, and there is no change in the Situation of them, but if in this Equilibrium we put an Iron-ſpatula into the fus'd Metal, the Force, which we give to it, will be imparted to the Fluid, and will agitate it which way we pleaſe; if the Expanſive Force of the Fire is likewiſe increas'd, by which it becomes Superior to the Contractive of the Metal, it will boil up, and the Situation of the Parts will be chang'd, but this is not Eſſential to the Fluidity, but to the Motion of it.

And thus we may imagine that where the Expanſive Force of the Sun or the ambient Medium and the Contractive of any Matter are in an equal Balance, Water is produc'd, which tho' Fluid in it ſelf is perfectly Quieſcent in a Stagnation of it, and which we find the leſs Power the Sun has upon it, as in Winter, the more it's Contractive prevails, ſo far as at certain Seaſons it is chang'd into a perfect Solid; Theſe Phænomenons are not therefore owing to a difference of Situation in the Parts, but to a different Force, which is induc'd upon them, and if what we have ſaid is true in Reſpect of Water, it is no more impoſſible that it ſhould be produc'd in Perennial Fountains, where the Expanſive Force of the Sun, and ambient Medium are equally balanc'd with the Contractive of an Earthy Matter, than that Subterraneous Fires ſhou'd be caus'd by the Expanſive of the Sun being Superior to the inflammable Matter it ſets a-Burning, and which may continue for ever in that State.

The Diſſolution of Salts and Metals in their proper Menſtruums, is another Inſtance made uſe of by this Philoſophy to juſtify it's Aſſertions of Bodies, owing their particular Forms to the different Situation and Poſition of their Parts, whereas Diſſolutions are more rationally ſolv'd by an Expanſive Force in the Menſtruum acting upon the Contractive of the Salts or Metals; beſides it is abſurd to ſay, that a Diſſolution is cauſed by a various Situation of Parts, ſince that is cauſed by a Diſſolution, and it is ridiculous to ſay, that a Diſſolution is caus'd by an Agitation, that is a Diſſolution of Parts, without aſſigning the Cauſe of ſuch an Agitation or Diſſolution.

As to the Inſtance of Keys, Knives, Files, Saws, and various other Inſtruments made out of the ſame Matter, Iron, which obtain their particular Effects from the Peculiarity and Diſtinction of their Figures, and of Mechanical Engins deriving their Powers from their ſeveral Structures, even their Effects we have ſhewn in the following Sheets are owing to the Expanſive and Contractive Forces, without which their different Configurations wou'd ſignify no more than the drawing Lines and Figures upon a plain piece of Paper; 'tis the Force and Energy with which they are endu'd, and not the mere Figure of the Parts, which gives them that Importance of Action, and that Ability to produce the Effects we experience from them; what wou'd a Key perform, which, as we have ſaid, has the Nature of a Lever to remove the Obſtacle, which oppoſes it, without the Expanſive Force apply'd to it, in order to ſurmount the Contractive of the Obſtacle? Or a Knife, which has the nature of a Wedge, without a like Expanſive Force actuating and envigorating it againſt the Contractive it is deſign'd to ſubdue? Wou'd a File or a Saw by it's Parts and the Diſpoſition of them, without the Expanſive Force of the Mind, and the Hand, which obeys it's Directions, diſſolve the Contractive of Matter? Or wou'd the Teeth of either of them ſignify much without the Reciprocation?

That the Reflections of Light, and that Colours, and particularly White, are owing to the Roughneſs of the Surface, on which it is Impingent, and conſequently to the Diſpoſition and Situation of it's Parts is not manifeſt, ſince Glaſs or Water may be Colourleſs or Tranſparent from their Expanſive Force aſſiſting and promoting the Progreſs or Tranſmiſſion of Light, which has alſo an Expanſive Force, thro' them, from a kind of Similarity and Congruency of Action, thus the Expanſive of Fire paſſes more eaſily thro' Air or Water, or a Body heated, which are Expanſive, than thro' Glaſs, or Solid, or cold Bodies, which are of a Contractive Nature, but when this Expanſive Force of Glaſs or Water is interrupted and broken, the Light is of Courſe obſtructed and ſtop'd, and where it do's not find a Paſſage, returns it's Force upon the ambient Plenum, which cauſes the Senſation of White in us, that is, it is not reflected in Rays to the Eye, but reſts Glowing in a pale and languid Flame on the Surface, where the Impaction is made, and by that means affects the Medium, which ſurrounds it, with that Action, which produces the above-mention'd Senſation in us.

SIR *Iſaac Newton's* Doctrine of Light and Colours we have in another Place conſider'd, and ſhall add ſomething farther concerning it in the following Section, and therefore will here only ſay, that it is not from thence prov'd, that Colours depend upon the different Figures and Poſitions of the Parts of Bodies, ſince thoſe Colours obtain a truer Solution from ſuppoſing there are various Compoſitions of the Expanſive and Contractive Forces in Bodies, upon which, when the ſame Similar and Homogeneous Light is incident, it receives different Impreſſions and Actions which communicated to the ambient Plenum ſtrike us with that Variety of Colours we behold in them; and from theſe Expanſive and Contractive Forces in Bodies it is, that we feel as well as ſee them, and that in various Ways and Manners as will afterwards appear.

OPTICKS are alſo alledg'd to ſhew, that diverſe Effects are produc'd from a change of Diſtance and Figure, as in plain, concave, and convex Speculums, we ſhall have occaſion to examine into the Foundations of this Science in another Place, and ſhall here only anſwer, that the Expanſive Force of Light, the Expanſive and Contractive of Glaſs and Quick-ſilver have no Inconſiderable, becauſe the chief Influence in the Production of theſe Phænomenons, without which, Figure and Diſtance would ſignify juſt nothing.

As to the Revolution of the Earth about the Sun with it's Axis parallel to it ſelf, and inclin'd to the Plane of the Ecliptick, by which all the Seaſons of the Year are produc'd, and the ſeveral Effects ariſing from them caus'd, they ſo manifeſtly depend upon the various Degrees of the Sun's Expanſive Force, and of the Earth's Contractive, that it wou'd be trifling to confute this Pretence for a Similar Matter, and the Parts, and Pores of it, with their different Situations and Textures, betwixt which, and the Inclination and Paralleliſm of the Earth's Axis, there is no imaginable Connexion.

THE laſt Argument to prove this Doctrine is drawn from the magnetick Attractions, which are alter'd by the Blow of an Hammer, and by the Heat of the Fire are annihilated and deſtroy'd, which will be a very good one, when it can be evinc'd, that there is no Expanſive Force in Percuſſion or in Fire, till then thoſe Forces will aſſume to themſelves the Prerogative of the Cauſe, and any change in the Situation of the internal Parts, if there is any, will be only an humble and paſſive Effect, deriv'd from it.

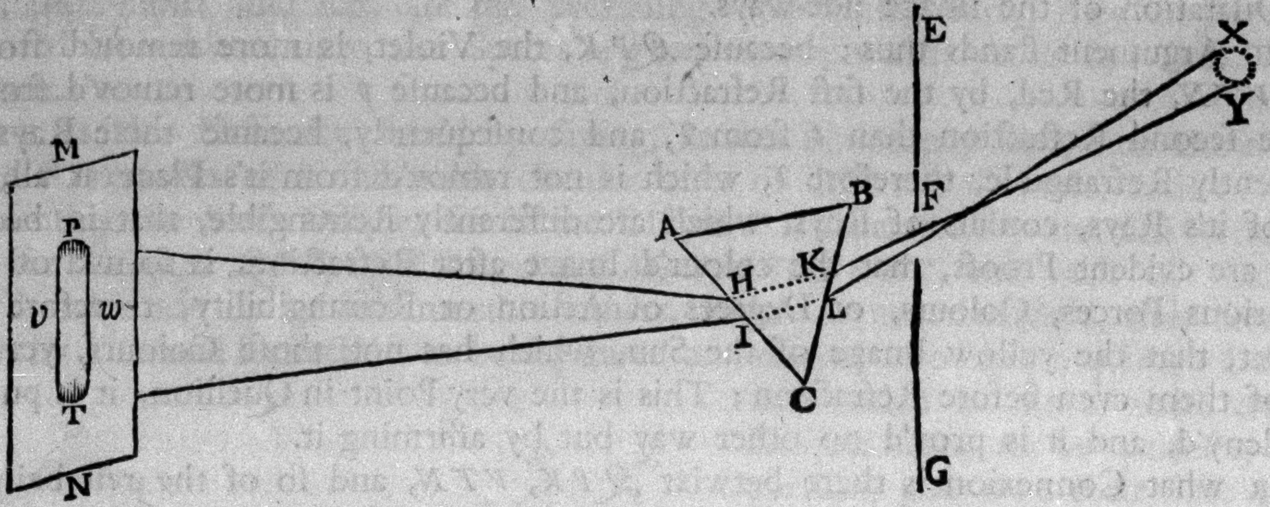
What I have formerly objected againſt the new Doctrine of Light, and Colours, and Sounds, farther Explain'd, and the true Theory of the Rainbow propos'd.

§. 20. IN Relation to the new Doctrine of Light and Colours, which was the laſt Thing I propos'd to ſpeak to, in the beginning of this Chapter, we ſaid in our *Principles of Natural Philoſophy*, Part 2. Chap. 3. Sect. 40. That the next Sort of Experiments, to prove the Rays of Light are differently refrangible Originally and before their primary Refraction, are ſuch as at the moſt demonſtrate them only to be ſo afterwards, *&c.* I ſhall therefore now, as a Supplement to what I have before offer'd on this Subject, go thro' the ſeveral Experiments, and ſhew that what I have there alledg'd is true.

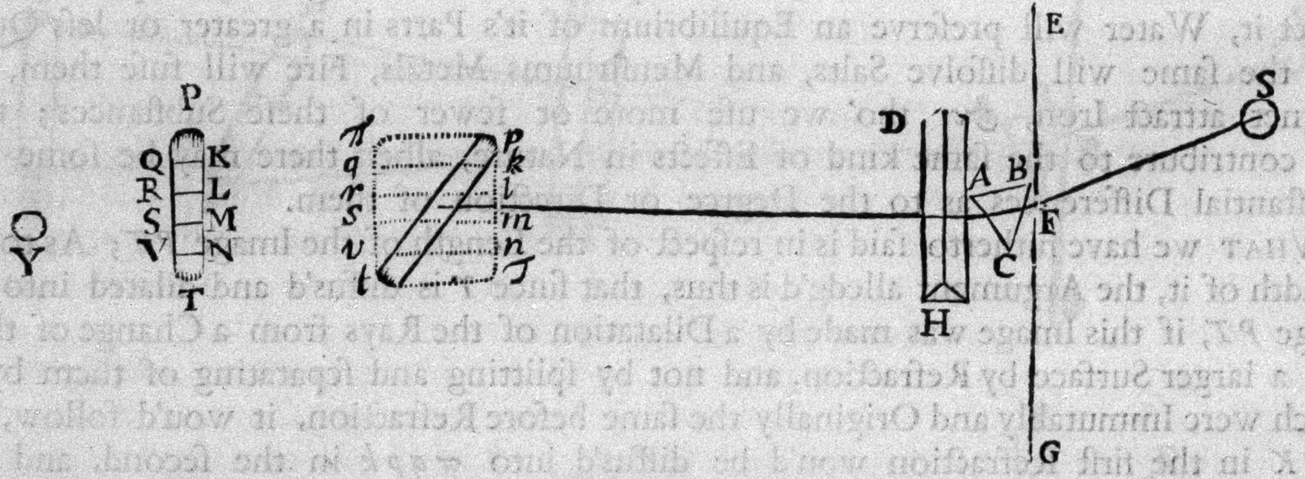
EXPERIMENTS the 1*ſt*, 2*d*, and 3*d*. we have already conſider'd in thoſe Principles, and ſhall now proceed to the 4*th*, it will be too Tedious for me to recount all the Experiments, and deſcribe them in Order, I ſhall therefore for the moſt Part only refer to them, with their Schemes, as they are deliver'd and explain'd to us by this Philoſophy, and reaſon and argue upon them from thence.

Sir *Iſ.* Newt. Opticks Prop. 2. Part 1. Book 1. Experiments 4, 5, 6, 7, 8, 9, and 10. Fig. 13, 14, 15, 16, 17, 18, 19, 20, 21, 22. Plate 3 & 4.

Experiment the *4th.* Fig. 13. which is by looking at the Foramen *F* in the Window-ſhut thro' the Priſm *ABC* is confeſs'd to be of the ſame Nature with the third, it ſhews the refracted Image of the Foramen to be Oblong, and not Circular, which the common and receiv'd Laws of Opticks wou'd require, and therefore, that, in equal Incidences of the Rays, there is a conſiderable Inequality of Refractions, but whence this Inequality ariſes do's not yet appear, and conſequently it is thus far acknowledg'd, that ſuch Inequality may be as well caus'd, by an Alteration of Light by the Priſm into variouſly colour'd Shadows, that is, by an Enervation and Diffuſion of the Rays in different Degrees, as by a Separation of Rays differently refrangible in their own Nature before their Tranſmiſſion thro' it.



Experiment the *5th.* Fig. 14. *S* is the Sun, *F* the Foramen of the Window-ſhut, *ABC* the firſt Priſm, *DH* the ſecond, *PT* the oblong Image of the Sun made by the firſt Priſm, when the ſecond is taken away, *pt* the Image made by the Croſs Refractions of both Priſms together, and *Y* the Image of the Sun made without any Priſm, or any Refraction at all; if therefore (it is ſaid) the orbicular Light *Y* is by the Refraction of the firſt Priſm drawn out and dilated into a long Image *PT* by a Diffuſion of Rays, the Light *PQK*, which is ſuppos'd to take up a Space of the ſame Length and Breadth with the Light *Y*, ought to be, by the Refraction of the ſecond Priſm, dilated and drawn out into the long Image $\pi q k p$, and the Light *KQRL*, into the long Image *kqrl*, and the Lights *LRSM*, *MSVN*, *NVT*, into ſo many other long Images *lrsm*, *msvn*, $n v t \tau$, and all theſe long Images wou'd compoſe the four Square Image $\pi \tau$, for the ſecond Refraction wou'd ſpread the Rays one way, as much as the firſt doth another, and ſo dilate the Image in Breadth, as much as the firſt doth in Length; But the event is otherwiſe, for the Image was not made broader by the ſecond Refraction, only became more Oblique, as repreſented at *pt*, it's upper end *P* being, by the ſecond Refraction, tranſlated to a greater Diſtance than it's lower end *T*; ſo then the Light, which went towards the upper end *P* of the Image, was, at equal Incidences, more refracted in the ſecond Priſm, than the Light, which tended towards the lower end *T*, that is the Blue and Violet, than the Red and Yellow, and therefore was more refrangible; The ſame Light was, by the Refraction of the firſt Priſm, tranſlated farther from the place *Y*, to which it tended before Refraction, and therefore ſuffer'd as well in the firſt Priſm, as in the ſecond, a greater Refraction, than the Reſt of Light, and by conſequence was more Refrangible



gible than the reſt even before it's Incidence on the firſt Priſm, and the ſame was try'd by a third and fourth Priſm, but the Rays, which were more refracted than the reſt in the firſt Priſm, were alſo more refracted in all the reſt, and that without any Dilatation of the Image ſide-ways.

THE Argument ſtands thus; becauſe *QPK*, the Violet, is more remov'd from *Y* than *VTN*, the Red, by the firſt Refraction, and becauſe *p* is more remov'd from *P* in the ſecond Refraction than *t* from *T*, and conſequently, becauſe theſe Rays are differently Refrangible, therefore *Y*, which is not remov'd from it's Place at all, nor any of it's Rays, conſiſts of Rays, which are differently Refrangible, that is, becauſe there are evident Proofs, that the colour'd Image after Refraction, is form'd of Rays of various Forces, Colours, or Degrees of Action or Refrangibility, therefore it is evident, that the yellow Image of the Sun, which has not thoſe Colours, yet conſiſts of them even before Refraction; This is the very Point in Queſtion, it is punctually deny'd, and it is prov'd no other way but by affirming it.

FOR what Connexion is there betwixt *QPK*, *VTN*, and ſo of the reſt being remov'd from their Places, and *Y* and it's Parts continuing in the ſame Place? betwixt *PT* being painted with Variety of Colours, and *Y* and it's Parts repreſenting only one? Is it not more natural to conclude from thence, that therefore *PT* is compos'd of different Sorts of Rays, and differently Refrangible, and that *Y* is not? Beſides what Connexion is there betwixt *QPK*, being more remov'd from *Y* than *VTN*, and *p* being more remov'd from *P*, than *t* from *T*? In the firſt Caſe two different Colours, Violet and Red, are produc'd, in the ſecond the ſame Colours are only preſerv'd, and therefore there cannot be the ſame Argument from *p* and *t* to *P* and *T*, as from *P* and *T* to *Y*.

IT is plain, the ſame Colours are preſerv'd thro' two, three, or more Priſms, and by conſequence their different Degrees of Refrangibility, but the Impreſſion upon Light is made by the firſt Priſm, and the Contorſion of the Image by the ſecond, without any Alteration of the Colours or different Actions of Light produc'd by the firſt; For this ſeems to be a general Law in Nature, that when once the Actions betwixt any two different Bodies are balanc'd and adjuſted, ſo as to produce a certain Effect, an addition of the ſame Kind of Action on one hand or another do's not change the Phænomenon as to the Nature of it, tho' it may as to the Degree, or Direction, or ſome other Circumſtance; Thus one, or two, or three Concave or Convex Glaſſes will have the ſame Effect to diſperſe or collect Light, and Speculums to reflect it, Water will preſerve an Equilibrium of it's Parts in a greater or leſs Quantity, the ſame will diſſolve Salts, and Menſtruums Metals, Fire will fuſe them, the Magnet attract Iron, *&c.* tho' we uſe more or fewer of theſe Subſtances; they will contribute to the ſame kind of Effects in Nature, albeit there may be ſome Circumſtantial Differences as to the Degree or Direction of them.

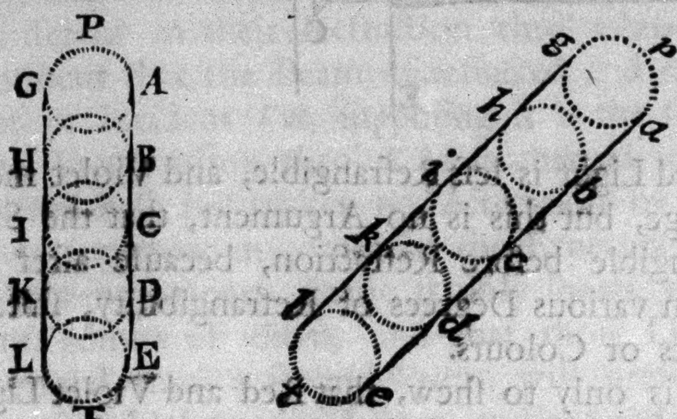
WHAT we have hitherto ſaid is in reſpect of the Length of the Image *PT*; As to the Breadth of it, the Argument alledg'd is thus, that ſince *Y* is diffus'd and dilated into the Image *PT*, if this Image was made by a Dilatation of the Rays from a Change of them into a larger Surface by Refraction, and not by ſplitting and ſeparating of them by it, which were Immutably and Originally the ſame before Refraction, it wou'd follow, that *QPK* in the firſt Refraction wou'd be diffus'd into *πqpk* in the ſecond, and that *QKRL*, *RLSM*, *SMVN*, *VNT*, in the firſt Refraction, wou'd be reſpectively diffus'd into *qkrl*, *rlsm*, *smvn*, *vntτ*, in the ſecond.

IN anſwer to which we muſt ſay, that altho' there is a Diffuſion of *Y*, or unrefracted Light into *PT*, the refracted thro' a Priſm, it is not from thence conſequent, that there ſhould be a Diffuſion of refracted Light or *PT* thro' a ſecond Priſm into *πτ*, for the Reaſons before offer'd.

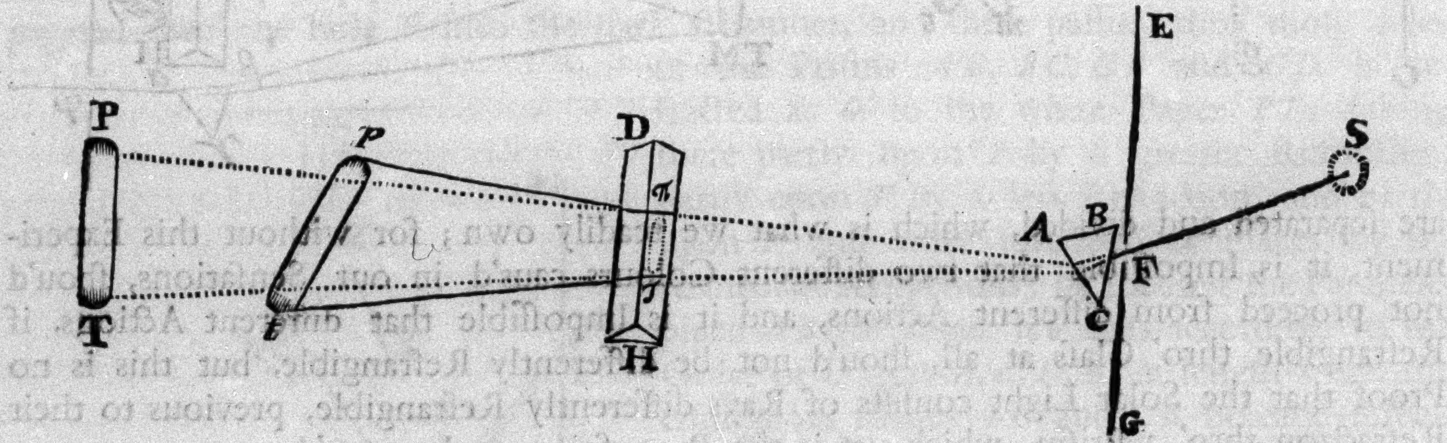
Farther, if *QPK*, *VTN*, and the reſt are to obſerve the ſame Laws as *Y*, in their Refraction, Violet and Red are ſuppos'd to have the ſame Properties as the pure Rays of the Sun, and *πpqk*, *vntτ*, ought not only to be of the ſame Length, but of the ſame Colours with *PT*, which wou'd be very abſurd to argue; we on the contrary, who affirm a Dilatation of the Image *Y* into *PT*, by an Alteration of the Properties of the Sun's Rays into Colours, deny, when they are thus alter'd, that they will obtain the ſame Effects of Dilatation or Change, becauſe Violet, Red, *&c.* are not the ſame as the Sun's Rays, but Shadows and Enervations of them.

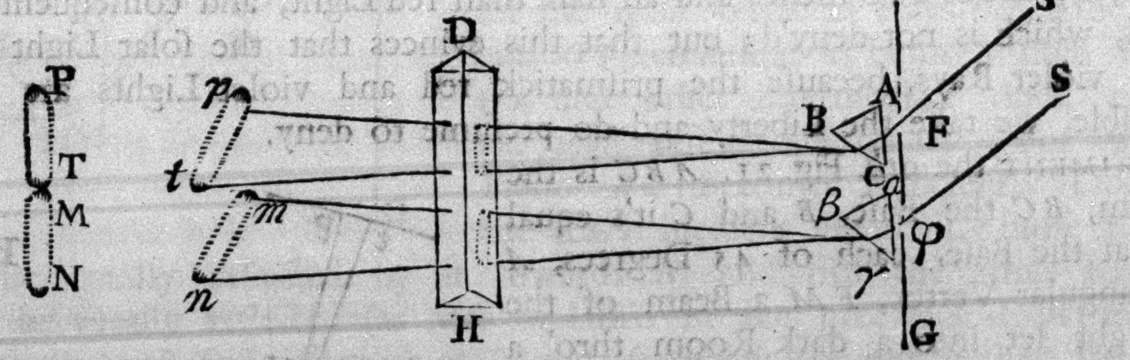
On the other hand, wou'd not this Objection be very Inconvenient to the preſent Hypotheſis of Diſſimilar Rays being ſplit and ſeparated by Refraction? Since *QPK*, *VTN*, and the reſt, each of them are blended with a thouſand different kind of Rays, tho' Violet and Red are the prevailing, and conſequently, they ought to be ſeparated and dilated into the Spaces *πpqk*, *vntτ*, which yet is not Fact or Experience.

Nor is this Difficulty ſolv'd by ſaying, as this Philoſophy do's, that the oblong Image *PT* conſiſts of innumerable circular ones of different Colours, each of them repreſenting the Sun's Diſque, for if the Diſque *Y* is ſeparated by the firſt Refraction into the Diſques *QPK*, *QKRL*, *RLSM*, *SMVN*, *VNT*, and each of theſe are form'd and made up of innumerable others, which is acknowledg'd, they certainly ought by a ſecond Refraction to be ſeparated and dilated into *πpqk*, *qkrl*, *rlsm*, &c. But which is more, theſe circular Diſques ſeem to be perfectly Chimerical, and owe their Riſe to the Breadth of the Image anſwering to the Sun's apparent Diameter, and to the Image being terminated by Semicircular Ends, which are very uncertain and precarious Proofs of it, eſpecially ſince Experiment the 11*th*, we find theſe Images of an Oblong and Triangular Form, ſuitable to the Figure of the Foramen; The Scheme Annex't expreſſes the imagin'd Faſhion of the Circular Diſques.

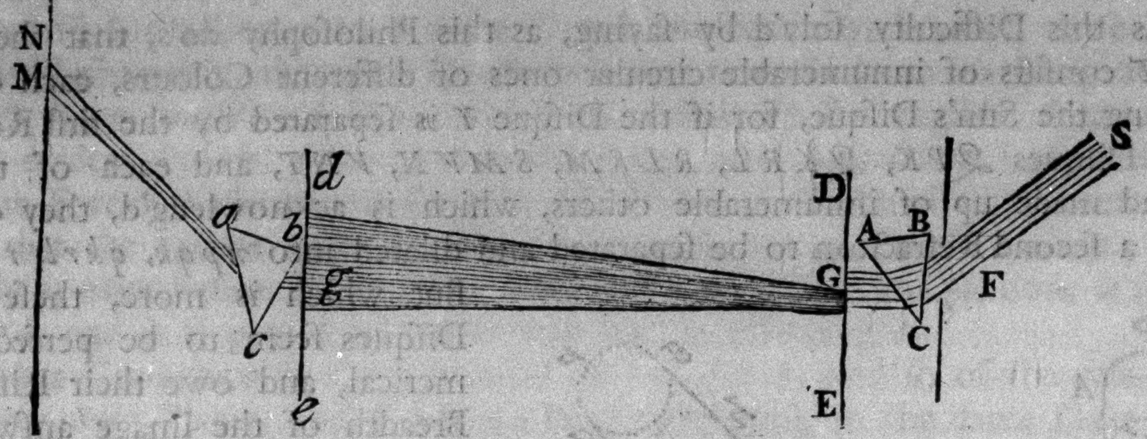


As to caſting the Image *Y*, by placing a Lens at the Foramen, without a Penumbra, from whence the Penumbra of the Images *PT*, *pt* wou'd likewiſe diſappear, that will equally agree with what we affirm, that the Refractions are perform'd exactly and regularly thro' the firſt Priſm, and continu'd and preſerv'd thro' a Second, or a Third; nor do Figures the 16*th*, where the ſecond Priſm is remov'd to ſome Diſtance from the firſt, and 17*th*, where two Images are painted upon the Wall in a direct Line by two diſtinct Priſms, and transfer'd from thence to an oblique Situation by the Interpoſition of a Third, evince any more than what we have already conſider'd and confuted.

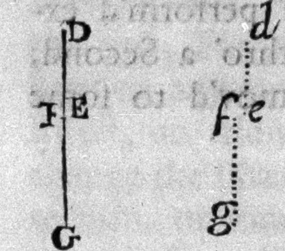


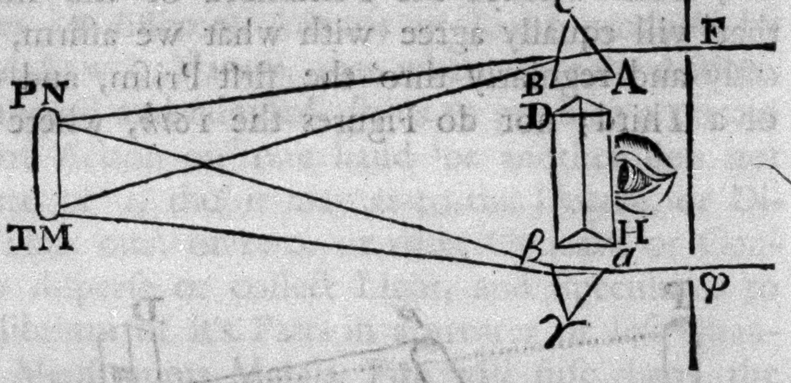


Experiment the *6th*. Fig. 18. only ſhews, that red Light paſſing thro' a ſecond Priſm *a c b*, is always refracted to a lower place *M*, in the oppoſite Wall, and Purple or Violet, paſſing thro' the ſame Priſm, and in the ſame Situation, is always refracted to an upper *N*, and the intermediate Colours to intermediate Places betwixt *M* and *N*, which is a Conviction, that red Light is leſs Refrangible, and Violet more, and ſo of the reſt, which we acknowledge, but this is no Argument, that the Sun's Light conſiſts of Rays differently Refrangible before Refraction, becauſe after Refraction different Lights or Colours obtain various Degrees of Refrangibility, ſuitable to the Nature and Action of thoſe Lights or Colours.

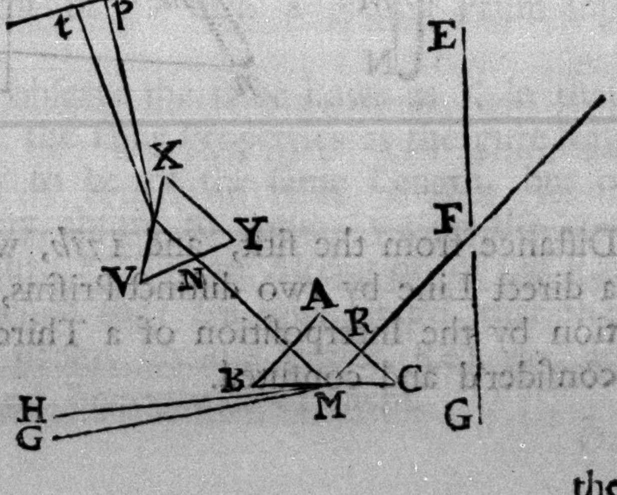


Experiment the *7th*. Fig. 17. 19, 20. is only to ſhew, that Red and Violet Lights produc'd by two Priſms, and view'd thro' a Third, are differently refracted by it, that is, tho' the red and violet Images are continu'd to each other, yet by Refraction they are ſeparated and divided, which is what we readily own; for without this Experiment, it is Impoſſible that two different Colours caus'd in our Senſations, ſhou'd not proceed from different Actions, and it is Impoſſible that different Actions, if Refrangible thro' Glaſs at all, ſhou'd not be differently Refrangible, but this is no Proof that the Solar Light conſiſts of Rays differently Refrangible, previous to their Refraction thro' a Priſm, which yet is the Propoſition to be prov'd.





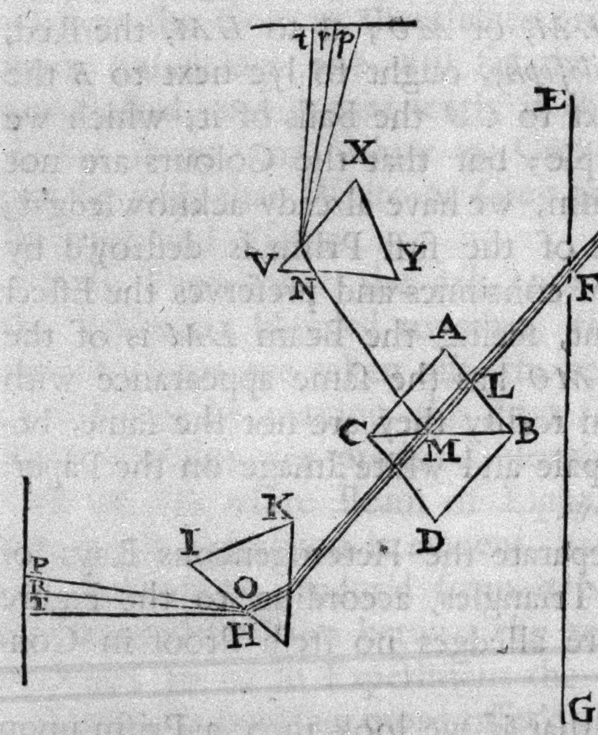
Experiment the *8th*, is of the ſame kind with the Former, namely, to ſhew that the violet priſmatick Light tranſmitted thro' a Lens, converges ſooner and nearer to the Lens, by about two Inches and an half than red Light, and conſequently is more refracted, which is not deny'd; but that this evinces that the ſolar Light conſiſts of red and violet Rays, becauſe the priſmatick red and violet Lights are differently Refrangible, we take the Liberty and do preſume to deny.



Experiment the *9th*. Fig. 21. *ABC* is the firſt Priſm, *BC* the Baſe, *B* and *C* it's equal Angles at the Baſe, each of 45 Degrees, *A* it's rectangular Vertex, *FM* a Beam of the Sun's Light let into a dark Room thro' a Hole *F*, one third Part of an Inch broad, *M* it's Incidence on the Baſe of the Priſm, *MG* a leſs refracted Ray, *MH* a more refracted Ray, *MN* the Beam of Light reflected from the Baſe, *VXY* the ſecond Priſm, by which this Beam, in paſſing thro' it, is refracted, *Nt* the leſs refracted Light of this Beam, and *Np* the more refracted Part of it; when the firſt Priſm *ABC* is turn'd about it's Axis according to the Order of the Letters *A, B, C,* the Rays *MH* emerge more and more obliquely out of that Priſm, and at Length after their moſt oblique Emergence are reflected towards *N,* and going on to *p* do increaſe the Number of the Rays *Np*; afterwards by continuing the Motion of the firſt Priſm, the Rays *MG* are alſo reflected to *N,* and increaſe the Number of the Rays *Nt,* and therefore the Light *MN* admits into it's Compoſition, firſt the more refrangible Rays, and then the leſs refrangible Rays, and yet, after this Compoſition, is of the ſame Nature with the Sun's immediate Light *FM,* the Reflection of the ſpecular Baſe *BC* cauſing no Alteration therein.

THIS Experiment therefore is an Argument for what we ſtill confeſs, that *MG* and *MH* are differently Refrangible and differently Reflexible, becauſe Violet and Red being different Colours have different Actions, and conſequently their Effects muſt be different in their Refraction thro' Glaſs, or their Reflexion from it, but it is no Argument that the Beam of refracted and reflected Light *MN,* is the ſame with the Solar or Incident *FR,* ſuppoſing it is the ſame with *FM,* ſince the Solar Beam *FR* in it's Tranſmiſſion thro' *RM* is chang'd into the Colours *MG, MH,* and then indeed the Baſe *BC* makes no Alteration by it's Reflexion; this therefore is no more convincing than any other of the Experiments to prove, that the Solar Light conſiſts of different Colours, ſeeing it only ſhews, that the Solar Light, when refracted by a Priſm, admits of them, and that thoſe Lights, when reflected from *M* to *N,* and tranſmited thro' a ſecond Priſm, will preſerve their Degrees of Refrangibility, and the purple Light proceed to *p,* and the red to *t,* nothing of which is conteſted, but affirm'd, at the ſame Time, that we cannot allow *FR* to be the ſame Light as *RM* or *MH, MG,* or *MN,* and ſo to *p* and *t*; for if it were ſo, any Glaſs Baſis, as well as *BC* the Baſis of the Priſm, ſhould have the ſame Effect, and reflect *MH, MG* in the ſame manner to *N,* and from thence thro' the Priſm to *p* and *t,* if *MH, MG* were originally in *FR,* before it's Ingreſs into the Priſm *ABC.*

EXPERIMENT the *10th.* Fig. 22. *ABC* and *BCD* are two Priſms ty'd together in the Form of a Parallelepiped, their ſides *BC* and *CB* being Contiguous, and their ſides *AB* and *CD* parallel; *HIK* is a third Priſm, by which the Sun's Light propagated thro' the hole *F* into the dark Chamber, and there paſſing thro' thoſe ſides of the Priſms *AB, BC, CB* and *CD* is refracted at *O* to the white Paper *PT,* falling there partly upon *P* by a greater Refraction, partly upon *T* by a leſs Refraction, and partly upon *R* and other intermediate Places by intermediate Refractions; by turning the Parallelepiped *ABCD* about it's Axis according to the Order of Letters *A, C, D, B,* at length when the contiguous Planes *BC* and *CB* become ſufficiently oblique to the Rays *FM,* which are incident upon them at *M,* there will vaniſh totally out of the refracted Light *OPT,* firſt of all the moſt refracted Rays *OP,* (the reſt *OR* and *OT* remaining as before) then the Rays *OR* and other intermediate ones, and laſtly the leaſt refracted Rays *OT*; For when the Plane *BC* becomes ſufficiently Oblique to the Rays incident upon it, thoſe Rays will begin to be totally reflected by it towards *N,* and firſt the moſt Refrangible Rays will be totally reflected (as was explain'd in the preceding Experiment) and by conſequence muſt firſt diſappear at *P,* and afterwards the reſt as they are in order totally reflected to *N,* they muſt diſappear in the ſame order at *R* and *T*; ſo then the Rays, which at *O* ſuffer the greateſt Refraction, may be taken out of the Light *MO,* whilſt the reſt of the Rays remain in it, and therefore that Light *MO* is compounded of Rays differently Refrangible, and becauſe the Planes *AB* and *CD* are parallel, and therefore by equal and contrary Refractions deſtroy one another's Effects, the incident Light *FM* muſt be of the ſame Kind and Nature with the emergent Light *MO,*



and therefore doth alſo conſiſt of Rays differently Refrangible; Theſe two Lights *FM* and *MO*, before the moſt refrangible Rays are ſeparated out of the emergent Light *MO*, agree in Colour and in all other Properties ſo far as the Obſervation of this Philoſophy reaches, and therefore are deſervedly reputed of the ſame Nature and Conſtitution, and by conſequence the one is compounded as well as the other; But after the moſt refrangible Rays begin to be totally reflected, and thereby ſeparated out of the emergent Light *MO*, that Light changes it's Colour from White to a dilute and faint Yellow, a pretty good Orange, a very full Red ſucceſſively, and then totally Vaniſhes; For after the moſt refrangible Rays which paint the Paper at *P* with a purple Colour are, by a total Reflexion, taken out of the Beam of Light *MO*, the reſt of the Colours, which appear on the Paper at *R* and *T*, being mixt in the Light *MO*, compound there a faint Yellow, and after the Blue and part of the Green, which appear on the Paper between *P* and *R*, are taken away, the reſt, which appear between *R* and *T* (that is the Yellow, Orange, Red, and a little Green) being mixt in the Beam *MO* compound there an Orange, and when all the Rays are by Reflexion taken out of the Beam *MO*, except the leaſt Refrangible, which at *T* appear of a full Red, their Colour is the ſame in that Beam *MO* as afterwards at *T*, the Refraction of the Priſm *HIK* ſerving only to ſeparate the differently refrangible Rays without making any Alteration in their Colours, as is ſaid will be more fully prov'd hereafter; The Reaſoning in the *Scholium* which follows is of a like Kind, and therefore we ſhall not here ſubjoin it.

In anſwer to the way of arguing upon this Experiment (for the Experiment we do not deny, nor any other of this Philoſophy) we ſay, that this is much the ſame Caſe with the Former, and that altho' the Beam *LM* may be of the ſame compounded Light with *MO*, as having been tranſmitted thro' the Priſm *ABC*, it is not manifeſt, that *FL* the incident and unrefracted Beam is thus compounded before ſuch Tranſmiſſion; and a moſt convincing Argument, that it is not, is, that if it were, by the turning about of the ſide *AB* of the Priſm, when the blue Rays of the Beam *FL* come to fall with a certain Obliquity, they ought to be reflected from thence, and after them the Green, Yellow, Orange, and Red ſucceſſively, in like Manner, as the Rays of the Beam *LM* or *MO* are reflected to *N*, and by that means transfer'd from *P*, *R*, and *T* to *p*, *r*, and *t*, one after another, but this do's not happen, from whence it is evident to a Demonſtration, that *FL* the incident Beam is not of the ſame compounded Nature with the refracted *LM*, or *MO*; as to *LM*, the Red, as we have ſhewn in our *Principles of Natural Philoſophy*, ought to lye next to *B* the refracting Angle of the Priſm, and the Purple next to *CA* the Baſis of it, which we find in fact, ſince *OT* is the Red, and *OP* the Purple; but that the Colours are not alter'd by a Tranſmiſſion thro' a ſecond or third Priſm, we have already acknowledg'd; It is ſaid, that *AB*, *CD* being parallel, the Effect of the firſt Priſm is deſtroy'd by the ſecond, which we deny, ſince the ſecond Priſm continues and preſerves the Effect of the firſt, as is plain from this very Experiment, ſeeing the Beam *LM* is of the ſame Kind and Nature with that of *MO*; that *MO* has the ſame appearance with *FL* is not Material, ſince we have evinc'd, that in reality they are not the ſame, beſides it is not certain, that *MO* do's not cauſe a pale and white Image on the Paper, whereas *FL* paints on it a ſtrong and vivid Yellow.

Experiment the 11*th*. Teaches us how to ſeparate the Heterogeneous Rays of compound Light into Circles, Parallelograms or Triangles, according to the Figure of the Foramen, which tranſmitts it, and therefore alledges no freſh Proof in Confirmation of the foregoing Doctrine.

Experiments the 12*th*, 13*th*, and 14*th* ſhew, that if we look thro' a Priſm upon a Circular Object illuminated by the Sun's Light, it appears oblong, confus'd, and indiſtinct, but if we look thro' a Priſm on the ſame Object illuminated with Red, Green, Blue or any other Homogeneal Light, it appears circular and perfectly defin'd, but this is no more than in other Terms to tell us, what we are inform'd of in the third Experiment, that the Sun's Light by a Priſm is refracted into various Colours; but that Homogeneal Light, or Colours produc'd by Refraction are not, this is no Argument therefore that ſuch Colours are originally in the Sun's Light, or that they are not made and produc'd by Refraction, tho' after their Production they become unalterable, and are never from thence Metamorphos'd or Chang'd.

Another Series of Experiments is to prove, that the Phænomena of Colours, in refracted or reflected Light, are not caus'd by new Modifications of the Light variouſly impreſs'd according to the various Terminations of the Light and Shadow, which is to demonſtrate the Falſhood of the *Carteſian* Hypotheſis, and ſignifies nothing to the evincing the Point in Queſtion, namely, that the Solar Light conſiſts of diſſimilar and differently colour'd Rays.

Sir Iſ. Newt. Opticks Prop. 1. Book 1. Part 2.

There are again other Experiments to ſhew, that all Homogeneal Light has it's proper Colour anſwering to it's Degree of Refrangibility, and that Colour cannot be chang'd by Reflexions and Refractions; that is Homogeneal Red, Green, or Blue Light, for Inſtance, after they are produc'd by the Priſm, are unchangeable, and each has it's peculiar Action belonging to it, or it's proper Degree of Refrangibility; but this is no Proof, that the Solar Light conſiſts of ſuch various Homogeneal Lights, only that the Priſm is capable of producing them, and which when produc'd, that there is no Alteration of Them.

Sir Iſ. Newt. Opticks Prop. 2. Book 1. Part 2.

As to what is ſaid, that Colours may be produc'd by Compoſition, which ſhall be like to the Colours of Homogeneal Light, as to the Appearance of Colour, but not as to the Immutability of Colour and Conſtitution of Light, and that thoſe Colours by how much they are more compounded by ſo much are they leſs full and intenſe, and that by too much Compoſition they may be diluted and weaken'd, till they ceaſe, and the Mixture becomes White or Grey, that alſo whiteneſs and all grey Colours may be compounded of Colours, and that the whiteneſs of the Sun's Light is compounded of all the primary Colours mixt in a due Proportion; a great Part of this is own'd, that the Lights produc'd by the Priſm may be variouſly mix't and blended, from whence new Lights will ariſe, which may be again ſeparated and diſtinguiſh'd, alſo that theſe colour'd Lights, produc'd by the Priſm, will conſtitute a White or Grey, which White or Grey is again reſolvible into thoſe colour'd Lights, of which they are form'd; but that the Solar Beam is either White or Grey, which is plainly Yellow, or that it is made up of differently colour'd and Homogeneal Lights is deny'd, and what is alledg'd in theſe two Propoſitions do's in Part confirm it; for it is ſaid, that the Colours, by how much they are more compounded, by ſo much are they leſs full and intenſe, and by too much Compoſition they may be diluted and weaken'd till they ceaſe, and the Mixture becomes White or Grey, therefore the White or Grey proceeds from a Weakneſs or Dilution of the Colours, whereas the Colours themſelves proceed from a Weakneſs and Dilution of the Sun's Rays, unleſs any one will ſay the colour'd Image is ſtronger than the Sun's Beam unrefracted, and conſequently if the Colours are an Enervation of the Sun's unrefracted Beam, and White or Grey is an Enervation of the Colours, I hope it will not be ſaid, that White or Grey is the ſame as a Beam of the Sun acting in it's full Strength and Vigour.

Sir Iſ. Newt. Opticks Prop. 4. & 5. Book 1. Part 2. Experiments 9, 10, 11, 12, 13.

And Experiments the 9*th*, 10*th*, 11*th*, &c. only ſhew, that, when the Colours of the Priſm are blended together, they produce a white Image, and that if any of thoſe Colours are taken out, the remaining repreſent the Colour of the Compoſition, as alſo that by making the Rays fall unequally upon the Paper, which receives the Rays, Colours are produc'd, nothing of which is contradicted by us; but that the Caſe of this white Beam of Light after Refraction is not the ſame with the Solar before it's Refraction is evident, becauſe the Solar Beam cannot be ſo manag'd, nor can Colours be produc'd from it by any Inclination of the Paper to it, and there is the ſame Diſtinction betwixt the refracted and unrefracted Beam, as there was before evidenc'd to be in Experiment the 9*th* and 10*th*, Part the firſt.

There is nothing more offer'd in this Theory of Light and Colours to prove the Truth of it, and it's fundamental Propoſition, namely, that the Solar Light conſiſts of differently colour'd Rays originally to it's Refraction thro' the Priſm, unleſs what we have already conſider'd in our *Principles of Natural Philoſophy*, and our Inquiry there, into this Doctrine, ſo that till this is anſwer'd we may be juſtly excus'd any farther trouble on this Head.

A Solution of Colours, and of the Rainbow, and concerning Sounds.

§. 21. I ſhall only here add, that the Colours of the Priſm ſeem to ariſe from what I there mention'd in thoſe *Principles*, namely Red from a Tranſmiſſion thro' the thinneſt Part of the Priſm or the very Edges of it, by which it's Colour is neareſt to the Sun's, and it's Rays the moſt vigorous and lively, and therefore the leaſt Refrangible;

gible; Orange, Yellow, Green, Blue and Violet paſs thro' thicker Portions of the Priſm, by which they loſe of their Action, become leſs and leſs vigorous, and therefore are more Refrangible and Weak, and depart more from the Life and Activity of the vivid Beams of the Sun, and accordingly impreſs upon our Senſations Colours, which are darker and more gloomy; for the Rays of Light, when they impinge upon the Body of the Priſm, will yet, it is probable, be tranſmitted thro' the Edges of it, where there is the leaſt Reſiſtance;

THAT the ſame is the Caſe of thin Plates of Glaſs, Air, or Water, which, when thin, repreſent theſe various Colours to us from a certain Proportion requiſite betwixt the Action of the Sun's Rays, and of Glaſs, Air, or Water thro' which they are tranſmitted;

THAT the Action of the Sun's Rays is of a moſt ſubtle and expanſive Nature, and that it cannot have any Effect to produce Colours by Tranſmiſſion, unleſs it is incident upon Bodies, which are very Minute and Thin, which have ſome Degree of the Expanſive to aſſiſt it's Tranſmiſſion, and but a ſmall Degree of the Contractive to impreſs an Alteration and change upon the Expanſive of the Sun's Rays, which is the Caſe of ſuch thin Plates;

THAT other groſſer Bodies, as colour'd Fluids and Solids, derive thoſe Colours from the Impreſſions, which they give to the Sun's Light diſpers'd thro' the Plenum from their own proper Expanſive and Contractive Forces, by which it receives a new Action, and thereby communicates to us thoſe Senſations of Colours; That therefore a Lamp or a Candle, enlightening the ſaid Plenum, cauſes the Colours of Natural Bodies, whoſe Expanſive and Contractive Forces are the ſame, to appear much the ſame, yet with ſome little Diſtinction ariſing from the different Nature of the Light of the Sun and a Lamp, which illuminate the ſame Plenum;

Sir Iſ. Newt. Opticks.

THAT the Experiment of Dr. *Halley* at ſeveral Fathoms deep in the Sea, where the upper part of his Hand was illuminated with Red, and the lower with Green, is a Conviction, that the Sun's Rays were only weaken'd to a Red in the firſt Caſe, and by penetrating deeper and being reflected, to a Green;

THAT the various Colours of the Rainbow ariſe from a different Enervation of the Sun's Rays by thin Plates of a watry Medium of different Thickneſſes or Conſtipations, the uppermoſt being the thinneſt, cauſe the leaſt Enervation, and the loweſt being the groſſeſt, occaſion the greateſt, from whence Red in the firſt caſe is produc'd, and Violet in the laſt, and ſo the intermediate Degrees of Colours in the intermediate Spaces;

THAT when the watry Medium is too Thin, as above the Red, the Rays paſs without any Alteration, and when it is too Groſs, as below the Violet, there is no due Proportion of Action betwixt the Sun's Light and the Medium by which an Alteration can be produc'd, and therefore we only ſee the plain watry Medium, in the ſame Manner, as it is in the Priſm, which when we come to a certain Thickneſs of it no Colours are produc'd, and we only perceive the Tranſparency of the Priſm it ſelf; or elſe, which I rather believe, it is becauſe the Expanſive Force of the Sun is too great for the Contractive of the watry Medium, and by that means diſſipates and ſurmounts it;

THAT the Eye is made ſenſible of theſe Alterations in the Sun's Rays, incurring upon different Mediums, not by the imaginary Refractions and Reflections of Light, propos'd by *Deſcartes*, but by thoſe different Actions communicated to the Plenum, which conveighs theſe Notices to us, and by the Intervention of which, and our Union with it, we are inform'd of all the various Changes we obſerve in Nature, which when differently affected we are ſo too, not only in our Sight, but in our Hearing, Smelling, and Feeling, which Impreſſions yet were never thought to be imparted to us by ſuch fancy'd Reflections and Refractions;

To explain this Theory ſtill farther, It is known and confeſs'd, that a Rainbow never appears, but when the Air is moiſt and dewy, after Rain, and when the Sun ſhines out directly oppoſite to it, in this Situation of the Sun, the Centre of Action is from thence, which by it's Expanſive Force, to a large Circuit round it, overcomes and diſſipates any counter Action againſt it from the Dew or Vapors, but the dewy or watry Medium preſſing and contracting againſt this Expanſive Force, at length, when the Rays of the Sun become more Oblique, is capable of making ſome Reſiſtance to it, and the greateſt Preſſure or Reluctance to the Expanſive Force of the

Sun being from the innermoſt Circle, becauſe it do's not only preſs it ſelf againſt it, but is back'd and enforc'd by all the ambient Circles which ſurround it, and whoſe Preſſure tends the ſame way, the innermoſt Circle for that Reaſon will be the groſſeſt, from whence the Expanſive Force of the Sun being there moſt reſiſted, it's Rays become of a blackiſh or purple Colour;

THE next Circle being leſs conſtipated, and denſe, and preſſing leſs againſt the ſame Expanſive Force of the Sun's Rays, becauſe it has fewer ambient Circles to ſtrengthen it's Preſſure, changes the Sun's Rays to a Blue, the next to a Green, and the ſubſequent ones to Yellow and Orange, till at length where the outermoſt Circle becomes the weakeſt in it's Preſſure, Reſiſtance and Contraction by the dewy Medium being now Rarer, and having fewer ambient Circles to ſupport it, the Rays of the Sun and the Expanſive Force of them being leaſt reſiſted are form'd into a Red, which compoſes the *Primary Iris*; After which the Expanſive Force of the Sun's Rays meeting with no conſiderable Oppoſition, they paſs on without any remarkable Phænomenon from them for ſome Space, till now becoming more oblique, and more weak, the Rarity of the dewy Medium is capable of making a new Impreſſion upon them by changing them into Red tho' a fainter one than before, becauſe the Action on both Hands, both of the Sun and of the Medium, is more languid, after which the Rays of the Sun and their Expanſive Force growing ſtill more oblique and weaker and the dewy Medium being much the ſame, as being now upon it's Termination, the Sun's Light is vary'd into Orange, Yellow, Green, Blue, and Purple by ſo many Degrees of Enervation, till the dewy Medium being ended the Rays of the Sun take their Progreſs as uſual without any Impediment or Oppoſition to them, which ſeems to be the true Reaſon of the *Secondary Iris*;

AND from hence may be given a full Account for the different Heighths of the *Iris* from 41 to 45 Degrees, which is not done in any other Hypotheſis, with many Phænomenons of it beſides, which have not been hitherto explain'd, It alſo appears at ſuch a certain Depth of the Atmoſphere, and at ſuch a Diſtance from the Sun, and on the oppoſite Side to it, becauſe the Rays ſurmount all Oppoſition upon their firſt Ingreſs into the watry Medium, but afterwards penetrating farther, and growing weaker, they are chang'd by the Contractive Force of the ambient Dew into the Colours, and in the Manner we have mention'd;

THAT the Expanſive Force of the Sun acts in the Manner I have recounted is not difficult to apprehend, and I believe will be readily own'd, but that the dewy Medium ſhou'd act by a Contractive Force againſt it, will not be ſo ſoon imagin'd, till we come to be convinc'd, which will be ſhewn in the following Sheets, that all Nature conſiſts of theſe two Forces, and that all the Phænomenons in it ariſe from their mutual Conteſts and Conflicts with each other;

THE Account of the Rainbow above-mention'd is farther confirm'd by what every one may obſerve of a Candle burning in the Dark, and in an open and moiſt Air, which if you look upon at ſome Diſtance is encompaſs'd with an illuminated Medium, and afterwards with Purple, Blue, Green, Yellow, Orange, and Red Circles, repreſenting the Colours of the Rainbow, which can be no otherways ſolv'd than upon the foregoing Hypotheſis.

Our Principles of Philoſophy and Chapter upon Sounds, and the ſecond Edition of Sir Iſ. Newt. Principles upon that Head.

As to the Doctrine of Sounds, which we had in our *Principles of Natural Philoſophy* argu'd againſt, the Preſent has been ſo complaiſant to thoſe Reaſonings and to the *London* and *Paris* Experiments, as to alter it's Calculations from betwixt 920 and 1085 Feet, which Sound performs in a ſecond, according to it's firſt Edition, to 1142 in it's ſecond Edition; ſo eaſy it is for this Philoſophy to change and vary it's Principles, as new Matters of Fact ariſe, to which it as readily accommodates it ſelf, as the Chamæleon to the Air it breaths in; but beſides the Velocity of Sound, which in Eccho's is exceeding great and impoſſible to be aſcertain'd, from which yet theſe Calculations are fram'd, the Expanſive and Contractive Forces of Bodies are ſo infinitely various, from which Sounds are really and in Nature produc'd, which will be afterwards ſhewn, that it is Vain and Idle to imagine they can be exacted to any Mathematical Rule of their Progreſſion.

Concluſion upon the Epicurean *Philoſophy.*

§.22. Having therefore thus far conſider'd the *Corpuſcular* Philoſophy, or the Philoſophy of Similar and Homogeneous Matter, and the Atoms of it, which I call the *French* Philoſophy being taught indeed originally by *Epicurus*, but reviv'd by *Deſcartes*, and patroniz'd by *Gaſſendus*, who writ the Life of that Philoſopher very much in favour of him; and having likewiſe conſider'd the Improvements upon it from our own Nation, who have added a Vacuum to it, which *Deſcartes* ſhou'd have done, it being Impoſſible to maintain a Plenum, and a Similar and Homogeneous Matter together, I ſhall now take my final leave of it, and proceed to what may be juſtly term'd the *Italick* Philoſophy, or the *Mechanical*, being principally deriv'd from *Galileus*, taken up by *Borellus*, and eſpous'd by *Kepler*, *Chriſtian Hugens*, and Sir *Iſ. Newton*, and which Philoſophy likewiſe agrees ſo far with the former, as to affirm a Similar Matter, and the Atoms of it, to which they have, with ſome kind of Senſe and Conſiſtency with themſelves, annex't a Vacuum, by which it becomes the entire Syſteme and Doctrine of *Epicurus*; but then again, they have with ſome Abſurdity join'd a Deity to this Similar Matter, Atoms, and a Vacuum, which their Maſter more truly, tho' perhaps not more prudently rejected from it, and left his Similar Matter very honeſtly, and the Atoms or Particles of it, to their own Actions, after he had contriv'd Space and Room enough for them, in which they were at Liberty to perform their random Motions and Vagaries.

Sir Iſ. Newt. Princip. Lib. 3. Pag. 482. Edit. 2.

HOWEVER this Philoſophy has been ſo Indulgent to what we had mention'd in our *Principles*, Chap. 1. §. 16. That we ſhould make the Demonſtration of *Religion* the *End* and *Concluſion* as well as *Deſign* of all our Speculations, as to annex an Explication of what it means by a God, tho' not a Demonſtration of one, at the End of it's ſecond Edition, which was wanting in the firſt; but it's Atoms, which were Immutable, and it's Vacuum, which was Infinite, Eternal and Unproduc'd, wou'd not allow it to acknowledge, that the Intelligence was an *Anima Mundi*, or had any Connexion with Nature, or any Union with it, or was in any Senſe a ſource from which it was deriv'd, only that it was a Being, which was an *Imperator Univerſalis*, or Lord Paramount to theſe Atoms, and guided and conducted them as he pleas'd; which is ſaying nothing at all in the Proof of a God, but forming a Creature of our own Fancies, which we ſet at the Head of our imaginary Atoms, and is, in Reality and Truth, a Fineneſs, which *Epicurus* had not the Wit, or too great a Simplicity in his Notions, to think of; for when he had made all to depend upon Atoms, and the Gravity of them, and upon a Vacuum, he juſtly concluded, that he had effectually diſcarded *Anaxagoras*'s Mind or Intelligence out of the World, and therefore, for which the *Athenians* valu'd him, that he had nothing remaining to profeſs of Religion, but to expreſs himſelf hearty for the Gods of his Country, without having any real Eſteem for them, and which is pretty evidently the Caſe of ſome of our Modern Philoſophers.

IF any one ſhall now ask me, whether therefore we maintain the Plenum of the Ancients, and that God and Matter are the Principles of all Things, and that Matter, in Conſequence, is Eternal and Unproduc'd;

WE anſwer firſt, That we are under no Obligation from what we have hitherto alledg'd to aſſert any ſuch Doctrine, all that we have endeavour'd to ſhew and evince is, that the current Opinions of the oldeſt and moſt Celebrated Philoſophers of *Greece* and *Phœnicia* were on the Side, not of a Vacuum, but a Plenum, and that the Wiſeſt and Beſt Men eſpous'd the Latter, whilſt the Former was defended by none but by the Atheiſtical and the Vicious.

SECOND, But to ſatisfy this Queſtion more directly, we anſwer, That with the Ancients we affirm a Plenitude of Corporeal Being or Matter, which yet we ſay and ſhall prove, is not a Self-exiſtent Principle, but is deriv'd from and created and form'd by God, and that it could not ſubſiſt one Moment without him; whether this Production of the τὸ πᾶν, or the Univerſe, or the Material Plenum was in Time or from Eternity, Reaſon cannot determine, and therefore muſt be ſubmitted to Revelation, becauſe in an Eternal Succeſſion of Ages, there is no point of Time, in which the Infinite Mind was not equally capable of exerting it's Almighty Faculties into Creation, and conſequently what admitted of no Limitation from his Power, muſt receive it from his Will, which it is Impoſſible for us to know without ſuch Revelation.

CHAP. II.

Concerning the Principles of the Mechanical Philoſophy, and the Matter and Motion aſſerted in it, as alſo of Space, Place, Time or Duration, and Celerity.

§. 1. WHAT has hitherto engag'd our Enquiries has been the certainty of an exiſting Nature in general, the Opinions concerning a Vacuum and a Plenum, and the Philoſophy of Matter with the ſeveral Properties of it, it's being Extended, Solid, and Impenetrable, Diviſible, Moveable, *&c.* Cold, Heat, Hardneſs, and Softneſs, as alſo the Sounds, Taſts, Smells, Colour and the like, which we in fact Experience reſult from it, and the Theory of the Rainbow, which concluded the firſt Part of our Examination into the Principles of natural Knowledge; we have from thence proceeded in the Courſe of our Studies, to ſhew the Infirmities and Weakneſs in the various Hypotheſes of the Reflection and Refraction of Bodies, and in conſequence, of that of Light, which carry'd our Searches into the Principles of Opticks, and the Solutions they give of Viſion, of concave and convex Glaſſes, the Conſtruction of Microſcopes and Teleſcopes, and the numerous Phænomenons in that Science, all which we ſhall at preſent omit, and we ſhall now therefore go on to conſider, the Philoſophy of Matter with that of Motion, and the Laws and Hypotheſes which have been rais'd to account for them, and as Opticks was one Part of what may be term'd the active Philoſophy in oppoſition to the Corpuſcular, ſo this is another.

Two Parts in Philoſophy, the Corpuſcular and the Active, the former of which has been conſidered, and the latter is reſolv'd Principally into that of Light, and Opticks, and Mechaniſm, or Motion.

§. 2. IN the Theory of Mechaniſm or Motion, there are therefore four Things to be conſider'd; Firſt, what Motion is, Second, the Nature of that which is mov'd, Third, the Place which that which is mov'd poſſeſſes, as well as the Space thro' which it moves, and laſtly, the time which it takes up in it's Motion; Conſequently to determine the Motion of Body, and what Laws it obſerves, we are to inquire in general; Firſt, what Motion is, Second, what Body or Matter is, Third, the Meaning of Place, and what real Space is, and Fourth, the Notion of Time.

In the Theory of Mechaniſm or Motion, four Things to be conſidered.

§. 3. As to what reſpects Motion it will not I am apt to think be neceſſary to prove there is ſuch an appearance in Nature, becauſe it is as plain and manifeſt as any thing in it, and thoſe who have rais'd Difficulties againſt it, as *Diodorus* or *Zeno*, or whoever elſe, argue againſt it upon a Suppoſition of Space and Body exiſting, which are no more demonſtrable or apparent than Motion it ſelf is, for it is only by our Senſes that we know there is Space or Body, and by the ſame we are convinc'd, that there is Motion likewiſe.

Motion as plain and evident as any other Phænomenon in Nature.
Dr. Keill Lect. 6. Int. ad Ver. Phyſicam p. 57.

§. 4. WHAT Motion is therefore we are next to examine; if it is a Tranſlation of Body out of the Vicinity of a certain Similar Homogeneous Matter, which ſurrounds it, into another, be it ſubtle or otherwiſe, whilſt the Notion of Matter continues the ſame, 'tis a Tranſlation or Motion of Body out of it ſelf into it ſelf, which is impoſſible, unleſs it be allow'd that a Penetration of Dimenſions is not ſo, or it is the ſame as to ſay, that Gold can move in it's own Subſtance; if Motion is affirm'd to be a Tranſlation of Matter out of one Part of Vacuum into another, then it is evident a Vacuum is taken for granted as before a Similar and Homogeneous Plenum was, neither of which are prov'd according to what has been alledg'd in the firſt part of our Examination into the preſent Philoſophy, that there is Motion is evident, but that it is in a Vacuum or a Similar and Homogeneous Plenum is not ſo evident, till the one or the other is demonſtrated, which as we have ſhewn cannot be done.

Neither the Carteſian *nor* Newtonian *account of Motion agreeable to Nature.*

§. 5. FROM what has been ſaid in the foregoing Section, it is plain that the Definition of Motion in general, is ſuited to the ſeveral Hypotheſes of a Vacuum, or a Similar and Homogeneous Plenum, neither of which are true in the Senſe which the Modern Philoſophers affirm, as we have in the firſt Part of this Philoſophy endeavour'd to evince, namely, that the Vacuum of Sir *Iſaac Newton*, and the Plenum of *Deſcartes* are equally Chimerical and Abſurd.

Becauſe the Carteſian *Plenum and the* Newtonian *Vacuum are equally abſurd.*

§. 6. REAL

Motion is to be defin'd by the ſeveral Particulars which enter into the complex Idea of it.

§. 6. REAL Motion is not therefore to be ſolv'd or defin'd in general by the Hypotheſes of a Similar and Homogeneous Plenum or a Vacuum, but by conſidering the ſeveral Particulars which enter into our complex Senſation of it, which are recounted in §. 2. as Matter, Space, Place, and Time.

The Definition of Motion not clearer than the Idea which is endeavour'd to be explain'd, and what is meant by Philoſophers in Defining it is only to eſtabliſh the neceſſity of their own Hypotheſes of a Similar Plenum on the one Hand, or of a Vacuum on the other.

§. 7. As for Motion abſtracted from all it's Circumſtances, it cannot be better defin'd than by naming it a continual Alteration or Change of Diſtance, altho' any Definition of it is in ſome Meaſure improper, for the ſame Reaſon, as one of Sound or Colour wou'd be, our Senſes inform us of Motion (as they do of Sound and Colour,) and we cannot deſcribe it by any other Characters than ſuch as we receive from our Senſes, and therefore the Explanation will be no clearer than the Idea which is endeavour'd to be explain'd; This is very evident, which ſince it is ſo, ſome may be apt to wonder upon what account Philoſophers have taken ſuch Pains in defining Motion; But the Admiration will ſoon ceaſe, if we obſerve that under that pretence they lay a Foundation for their own Hypotheſes, Thus where one Sect has eſpous'd the Notion of a Similar Plenum, there Motion is a Tranſlation of Body out of the Vicinity of the Corpuſcles which ſurround it, into the Vicinity of others, that is, in ſhort, Motion is the moving of a Body in a Similar Plenum; On the contrary where another Sect has embrac'd the oppoſite Opinion of a Vacuum, with them Motion is a change of a Body's Primary Place, that is, Motion is the moving of a Body in an abſtracted Space or a Vacuum, and ſince Diſtance is alike, whether there is a Vacuum or a Plenum, they have not thought fit to make uſe of that Term, becauſe it wou'd be of no Service to the promoting their particular Doctrines, ſo that what we gain by ſuch Definitions is not a diſtincter Apprehenſion of Motion, but the advantage only of knowing what Opinion the Philoſopher is of, who propoſes them, and how careful he is to make us believe his own Hypotheſis is neceſſary to a right Conception of it.

The Explanation of what real Motion is and not an Hypothetick requires us to conſider what Matter is, which is mov'd. Deſcartes and Rohault, Sir Iſ. Newt. Def. Princ. Math. Dr. Keill Lect. 2. Intr. ad Ver. Phyſ.

§. 8. SETTING aſide therefore the ſeveral Hypotheſes introduc'd not to explain Motion, but to be affixt and made Eſſential to it, we ſhall conſider what real Motion is, and what is requiſite to the perfect underſtanding of it; The firſt thing requiſite (ſince we only at preſent enquire into external Nature, and not that of our Minds in which there is a Kind or Species of Motion obſervable, tho' different from that into which we now examine,) The firſt thing requiſite is Matter, for in real Motion there is always ſome material Being which is mov'd, the Definition of which, if not truly given, is one Argument againſt all the Reaſonings made uſe of in the preſent Philoſophy of Motion; It is defin'd to be a Subſtance, Extended, Solid and Impenetrable, Indifferent either to be mov'd or not to be mov'd, that is, it is entirely Sluggiſh and Paſſive, as well as ſuſceptible of any Motion, Figure or Form, which is conſequent upon it's being Paſſive.

The Definition of Matter ſuited to the Hypotheſes of Philoſophers but not agreeing with Nature either as to its Subſtance, Extenſion, or Solidity. Chap. 6, 7. Part 1. of our Principles of Philoſophy.

§. 9. 'TIS very certain ſuch a Definition of Matter, as this, is extremly well adapted to the Purpoſes of Philoſophers, which are that they may uſe it as they pleaſe, that they may divide, mangle, and ſhape it, as they ſhall find occaſion, which is done in the Corpuſcular Philoſophy, or ſubmit it to what Laws of Motion they ſhall think fit or agreeable to their Explanations of Nature, which is done in the Mechanical; on the other Hand, Matter is not ſo Tame and Submiſſive a Being, as they are willing to apprehend it; for firſt, we have before prov'd that it's Subſtance, as they term it, which is the Baſis and Foundation of the other Properties of it, is unexplain'd, and yet is as neceſſary to a real Knowledge of Matter, as any thing elſe which belongs to it, being that which connects and cements the ſeveral Qualities of it together, and from which they all reſult; Second, in reſpect of it's Extenſion, Solidity, Impenetrability, theſe have all been before conſider'd, and ſhewn to be different from what this Philoſophy imagines or conceives.

Not agreeable to Nature as to it's Inertia.

§. 10. THE next Property affirm'd in this Definition is the Inertia of Matter, in Relation to it's being mov'd or not, and that it is perfectly indifferent to Motion or Reſt in it's own Nature, than which nothing can be more falſe, ſince if we take any ſolid, conſiſtent, and heavy Body, as Lead, it has not that Indifference, becauſe 'tis very manifeſt it makes a Reſiſtance to Motion, whereas on the contrary in other Matter, as Fire, there is a Reſiſtance made to Reſt, ſo that Matter is ſo far from being in general Indifferent either to Motion or Reſt, that ſome Parts of it do moſt violently affect the one, and others the direct oppoſite, inſomuch as very difficulty to be put out of that State of Activity or Quieſcence which they have embrac'd, as is notorious to any one who knows how hard a thing it is to extinguiſh an outrageous Fire, or to move a Weight of ſeveral Millions of Tuns.

§. 11. If it is ſaid the Reaſon, why, in the laſt caſe, Matter, which is in it's ſelf Paſſive, makes a Reſiſtance to any Impreſſion which is ſtruck upon it, is, becauſe it has a Force of Gravitation; that Force is either in the Matter which Gravitates, or in that to which it Gravitates, if in the former, Matter is Active at the ſame time that it is ſuppos'd to be Paſſive, if in the latter, ſince that is Matter too, the Argument is ſtill Valid, If the gravitating Force is neither in the Matter which Gravitates, nor in that to which it Gravitates, it has a gravitating Force, and it has not, which is a Contradiction, for we do not now enquire what is the Cauſe of Gravitation, but whether there is not ſuch a Property or Effect in Matter, which is as plain and evident to our Senſes, as Extenſion or Solidity is.

Gravitation in Matter an Argument for it's not being endu'd with an Inertia or a Perfect Inactivity.

§. 12. We cannot but here farther obſerve one thing more in this Philoſophy, which ſeems to be very Strange and Surprizing, that whereas in the beginning of it, it ſuppoſes Matter to be perfectly Sluggiſh and Unactive, by that time it comes to the Concluſion, Matter is left with a Force and Activity able to keep the whole Planetary Syſtem within the Bounds of it's Orbits, by it's immenſe and prodigious Gravitation; from whence it is manifeſt, that however it might be neceſſary to make Matter an uſeleſs and paſſive Thing in order to turn it about, and project it this way or the other at Pleaſure, yet Truth wou'd prevail, and in the Proceſs of theſe Philoſophers arguings upon Nature, they were oblig'd to introduce a Force into Matter, which they wou'd not at firſt acknowledge, and own at the laſt that it was endued with a Power of Gravitation; So that if we compare the original Hypotheſis of this Philoſophy with the Concluſions of it, the one ſeems to be little leſs than a Confutation of the other, Matter is ſuppos'd to be entirely Paſſive, The Sum of all the Mathematick Reaſoning upon that Hypotheſis, is, that it has in every Part of it a Force of Gravitation, that is, that it is entirely Active, and if ſuch a Concluſion is not a Contradiction to ſuch an Hypotheſis, I cannot tell what is.

The Suppoſition of an Inertia in Matter, and the Concluſion from ſuch an Hypotheſis that all Matter Gravitates or is Active, is a Contradiction.

§. 13. Allowing however the Reſiſtance of Matter to Motion cou'd be accounted for by Gravitation, ſo as Matter ſhou'd, notwithſtanding that, be ſtill Paſſive, we ſhall yet want a freſh Solution for the oppoſite Quality obſervable in Fire, or in the Rays of the Sun, which do not make a Reſiſtance to Motion, but to Reſt; if this is done by any Æthereal Particles aſſembling together, ſince thoſe Æthereal Particles are ſuppos'd to be Matter, Matter will ſtill be Active; Whence that Action proceeds is not now the Queſtion, only whether there is ſuch an Action, which it is very certain there is, and which we can with no greater Reaſon deny to belong to the real Nature of that Matter, than Brightneſs or Heat, or Extenſion, or any other Quality which we obſerve in it. If any one ſhou'd argue with us, that Fire, which is endu'd with Motion, is Matter, and Lead, which is at Reſt, is Matter, and therefore Matter is Indifferent to Motion or Reſt, or has a perfect Inertia, the Sophiſtry is eaſily anſwer'd, by ſaying that Fire is Matter, and yet is not Indifferent to Reſt, and Lead is Matter, and yet is not Indifferent to Motion, and therefore Matter is not Indifferent to Motion or Reſt, the Caſe is, They who argue thus, ſpeak of a General, Fancy'd, and Abſtracted Matter, but we of a True and a Real.

The Activity of Fire and of the Rays of the Sun, an Argument for Matters not being endu'd with a perfect Inertia.

§. 14. Another Property which is ſaid to enter into the Definition of Matter is, that it is ſuſceptible of any Figure or Form which we can imagine; This likewiſe is well contriv'd by Philoſophers, to make Matter obedient to their Carving and Cutting it out into what Shapes or Figures they judge convenient to their ſeveral Purpoſes, but that Matter will yield to them in this is not ſo very certain, becauſe tho' we can by Superior Forces apply'd give what Impreſſion we think fit to Gold or a Diamond, yet we are not able to ſubdue Flame, and put it into what Figures we are deſirous it ſhou'd receive; The Reaſon of which is, that quieſcent Bodies may be conquer'd by an active Force, but Fire and Flame can't, and therefore to form a Notion of Matter's being ſuſceptible of any Figure, from our being capable of imparting it to ſome Portions of it, is at the beſt only a Partial defining of it, and even in ſolid Bodies this Property is not true, excepting where the Force is ſuperior to the Reſiſtance; as to any other Form of Matter beſides the Figure of it, we have no

Matter not ſuſceptible of whatever Form or Figure we pleaſe, becauſe ſome Parts of it may be ſo divided.

occaſion to conſider it, ſince, in this Philoſophy, the various Forms of Matter are owing to the various Figures and Textures of it's Parts.

Nor yet becauſe we can imagine Matter thus diviſible into certain Forms and Figures.

§. 15. If it is not upon the foregoing account that we ſuppoſe Matter to be ſuſceptible of any Figure, that is, becauſe we actually experience we can divide it at our pleaſure, which as we have ſaid is not true, it muſt be upon this, namely, becauſe we can conceive Matter to be ſo divided; but if, becauſe we can mentally divide Matter into any Figures, it is therefore really diviſible into them, it will follow, becauſe we can mentally imagine Matter not to be divided, but one continued Subſtance, therefore it is really from ſuch a Conception not diviſible into any; and in general, if Things exiſt according to our Imaginations, there needs nothing more to the Explaining of Nature, than for the Mind to imagine Nature is ſo, and from thence to conclude that it is.

If Matter is not juſtly defin'd by Philoſophers, real Motion is not, and as for abſtracted Motion it can ſignify nothing to the Explaining of Nature.

§. 16. Moreover we have ſufficiently conſider'd the Definition of Matter in the firſt Part of our *Principles of Natural Philoſophy*, and endeavour'd to ſhew the Notion, which all the Philoſophy, that has been hitherto propos'd, has entertain'd of it, is nothing elſe than a Creature of the Mind, and not any ways conformable to the real Nature of that Subſtance; which, if true, whatever is advanc'd concerning the Laws of Motion is falſe, if by that we mean real Motion, into which the Nature of Matter, or of the Being which is mov'd muſt be computed; if abſtracted Motion is intended, thoſe Laws, which are form'd from it, may indeed furniſh us with Principles to argue and build Theorems upon, as Extenſion do's in Geometry, but can ſignify nothing to the Explaining of real Motion, no more than the proving the three Angles of a Triangle are equal to two Right ones, or the Square of the Hypotenuſe of a Right-angled Triangle is equal to the Squares of the Sides, is of any Service to the informing us what real Extenſion is in Water, or Gold, or the peculiar Properties of it, as it exiſts in Material Beings,

If the Theory of Mechaniſm or Motion was true when apply'd to Pendulums, it yet wou'd not be ſo when apply'd to Fire and Flame.

§. 17. Lastly, if the whole Theory of Motion was Rational and Exact, as it is apply'd to conſiſtent Bodies, which are mov'd in Pendulums, or made to meet each other by a mutual Concourſe, ſuch a Theory could not explain the Action of Fire or Flame, ſince it is impoſſible to reduce it to a Pendulum, or to any Concourſe of hard and reſiſting Bodies, unleſs it can be prov'd, as we before obſerv'd, that a Reſiſtance to Motion, as in heavy Bodies, and a Reſiſtance to Reſt, as in Fire, are the ſame.

Space and Place the next Ingredient to be conſider'd in Motion which is either Abſolute or Relative.

Sir Iſ. Newt. Princip. Mathem. Defin. Dr. Keill Introd. ad veram Phyſ. Lect. 6.

§. 18. Having examin'd into the Idea of Matter, as it reſpects the Mechanical Philoſophy, the next Thing to be conſider'd, is the Space, which the Body, which is mov'd, either deſcribes, or poſſeſſes, the firſt is term'd Space, the latter Place, both which are diſtinguiſh'd into Abſolute and Relative; Abſolute Place or Space is call'd Primary, and ſuppos'd to be Similar and Immoveable, which continues one fixt and unalterable Expanſion, and do's not depend upon any References to certain Points, by which we judge of the Motion or Reſt of Body; Relative Space or Place on the contrary is determin'd by ſuch References. Thus, if we are in a Ship under Sail, whilſt we continue in the ſame Situation to all the Parts of it, there is a Relative Reſt to thoſe Parts, tho' there is an Abſolute Motion in Reſpect of there being a Change of Abſolute Space or Place, tho' not of the Relative, by the Ship's Moving.

Relative Space, Place or Motion of no Conſideration in Philoſophy, tho' uſeful in reconciling Religion to it.

§. 19. From whence it follows that, in actual Motion, or in a true Philoſophy of it, Relative Place or Space is of no Conſideration, it being only a Reference made by the Mind without any Reſpect to the Reality of Things; however one Advantage may be made from this Diſtinction of Abſolute and Relative Quantities, to wit, of Place and Space, and conſequently of Motion, that it gives a full Account of thoſe Paſſages in Holy Scripture which Philoſophy ſeems to contradict, as that the Earth ſtands ſtill, and the Sun moves round us, which tho' it may not poſſibly be true in an Abſolute Senſe, yet is ſo in a Relative, and it is more agreeable to think that the Scriptures ſpeak in a Common, rather than in a Philoſophick or a Mathematick Stile, ſince the Sun may with as great a Propriety of Speech be ſaid to move, if it only do's ſo Relatively, as if it Really did.

Abſolute Space or Place, as conſider'd in the Mechanical Philoſophy, an

§. 20. As to what concerns therefore Abſolute Space or Place, which is requiſite to real Motion, we have before ſhewn that Primary or Abſolute Place or Space, or Vacuum which is the ſame, is nothing but an abſtracted Idea of the Mind, and do's not furniſh us with any real Knowledge of the Nature of that Space which exiſts, from whence our abſtracted Notion of it is form'd by a partial Conſideration only of Length, Breadth, and Thickneſs, and neglecting the other Properties, which belong to it; and therefore upon this account likewiſe the preſent Doctrine of Mechanicks propoſes to us nothing more than a Theory or Contemplation of abſtracted Motion, which by §. 16. will be far from Informing us in any thing that is Real, and which is found in fact Exiſting.

abſtracted Notion and do's not exiſt in Nature.

§. 21. THE laſt Thing to be conſidered in Relation to Motion is the Time, which it takes up in it's Progreſs, which is in like manner, as Space, diſtinguiſh'd into Abſolute and Relative; the firſt is ſaid to flow uniformly without any Alteration, and the ſecond to depend upon the Meaſure we make uſe of to determine it, as the Motion of the Sun and Moon, which this Philoſophy takes notice of, or the Succeſſion of Ideas, which is alledg'd by another, which we may call the Metaphyſical.

Time another Ingredient of Motion is likewiſe defin'd to be Abſolute or Relative.
Sir Iſ. Newt. Princ. Math. Definit.
Dr. Keill Introd. ad ver. Phyſicam.
Mr. Locke.

§. 22. As to what Reſpects Abſolute Time, which is Uniform, and paſſes one Minute after another without the leaſt Acceleration or being Retarded, it is manifeſt, as in Abſolute Space, that this is alſo a Notion form'd by the Mind, and not agreeable to Nature it ſelf; for how is it poſſible for us to know what Time or Duration is in Experience and Fact, that is, what it Really is, and as it Exiſts, excepting by the Obſervation of that External Motion, as of the Sun or Moon, which is without us, or that Internal one, which we perceive in our own Minds? for ſuppoſing Time to flow uniformly without any Experience on our Part, that it do's, it is the ſame as to ſuppoſe an uniform, uninterrupted Space, without any ſuch Experience that it really Exiſts; and therefore, as the Latter has only it's Exiſtence in the Mind, ſo we may reaſonably think the Former only has; beſides which, we have before ſhewn, that our Conception of Matter's being diviſible is no Proof that it is, and for the ſame Reaſon, unleſs it is juſtify'd by Experience, our Conception of Time being uniformly continu'd, is no Proof of it's being ſo; What I mean in general, and which may be concluded from what has been ſaid, is, that we muſt form our Notions of Time, as well as of Space, not from any arbitrary Abſtractions of the Mind, but from our real Experience and Obſervations, and our juſt and plain Reaſonings upon them.

Abſolute Time in the Senſe of this Philoſophy, as much a Creature of the Mind as Abſolute or Primary Space is.

§. 23. FROM what has been ſaid it is evident, that, as in Space, the Abſolute or Primary, which is an abſtracted Idea, was only conſidered, in this Philoſophy's Account of Motion, ſo in Time or Duration, the Abſolute or Abſtracted, not the Real, is likewiſe aſſum'd, and is ſuppos'd to flow uniformly by a continual Succeſſion of Moments or Inſtants without any Change or Variation, which we affirm to be a Creature of the Mind, and that real Time or Duration, and our Notion of it muſt be deriv'd from ſomething, which falls under our Experience and Obſervation, as exiſting in Nature; for if we our Selves did not exiſt, nor any Thing elſe beſides us, Time or Duration wou'd not, But as we can have no Idea or Imagination of Nothing, and as Time or Duration is neceſſarily connected with Being, ſo we can have no Conception of no Time or no Duration.

The Notion of Time or Duration ought to be deriv'd from Obſervation and Experience, and not from our Abſtractions.

§. 24. SINCE therefore our Notion of Time or Duration muſt be deriv'd from Exiſtence, which it always accompanies, and from which it is never ſeparated, it muſt be from thence, and from our Obſervations upon it, and from the Nature of it, that we are to fix and ſettle our Apprehenſions of real Time and Duration, both as to it's Being, and as to it's Meaſure; in reſpect of the firſt of which, we are ſufficiently inform'd of it from our own Exiſtence, and from the Succeſſion of our Ideas in our Minds, as likewiſe from all the Beings, whether Quieſcent or in Motion, which exiſt without us; the principal and only Enquiry therefore is, what is the real Meaſure of Time or Duration, and whether it flows uniformly and by a Succeſſion of certain and determin'd Inſtants and Moments or not.

Time or Duration, and the Meaſure of it, Two Things.

§. 25. IN order to examine into this, the juſteſt way for us is to conſider the ſeveral Beings in Nature, which come under our Senſes or Obſervations, and from thence to know, whether any of them can afford us a Solution of what is requir'd, that is, can give us a Standard or Meaſure of Time or Duration; and here we are not at firſt to take it for granted, that Time or Duration do's flow uniformly by a Succeſſion of determin'd Moments or Inſtants, but to enquire whether it do's ſo, either from what we obſerve in Bodies, which are Quieſcent, or which are in Motion, or from the Succeſſion of Ideas in our own Minds; and if we cannot prove

The Meaſure of Duration to be aſcertain'd from conſidering the ſeveral Beings which exiſt, and how far they are ſufficient for that End.

ſuch a Time or Duration in fact from Beings, which exiſt, it is plain and evident, that it is a Creature of the Underſtanding, form'd and made by it without any Affirmation from Nature, or from Things as they really Exiſt.

Any certain or determin'd Moments or Inſtants of Time following one another in an abſolute and unvary'd Succeſſion not concluded from Beings as they exiſt.

§. 26. But before we come to enquire what Beings, as they really Exiſt, do preſcribe to us to think, in reſpect of the Meaſure or Standard of Duration, it will be neceſſary for us to ſhew, in Order to obviate the Prejudices, which have been hitherto receiv'd, that a Succeſſion of certain and determin'd Inſtants of Time or Duration is a mere Chimæra, and a thing of Imagination only, for there is not any real Being, which do's actually meaſure out Time or Duration in that Manner; Bodies which are Quieſcent, as this Table or Paper, on which I write, do exiſt Moment after Moment, but they do not inform us, by their Quieſcence, what Duration that Moment has, or what the Meaſure of it is, or whether one Moment or Inſtant of Time may not be different from another, they only aſſure us, that they do exiſt, and that by Conſequence they have Time and Duration in general belonging to them; Bodies which are in Motion, tho' we ſhou'd know the preciſe Moments, in which they move, as of the Earth and Moon in their ſeveral Orbits, ſo as from thence to be able to calculate the Solar and Lunar Eclipſes to a Minute, Theſe cannot yet aſſure us, that Time or Duration flows any more according to the uniform Inſtants, which are proportionate to their Revolutions, Namely of the Earth about it's Axis in 24 Hours, and about the Sun in 365 Days, and of the Moon about the Earth in 27 Days and 7 Hours, than according to any other uniform Inſtants, which may be computed and eſtimated from any different Revolutions; For ſuppoſing the Earth had Revolv'd round it's Axis, in half the Time, in which it now do's, and we were to divide that Duration into 24 equal Parts, and were to name them Hours, as we have done the 24*th* Parts of the Preſent Revolution, every Hour wou'd be in ſuch a Caſe as ſwift, that is, as ſhort again, as what we now Experience, and conſequently every Minute, or the ſmalleſt Inſtant of ſuch a Duration, wou'd be Proportionably Accelerated. Thus, if the Computations of Aſtronomers are true, *Venus* performs it's Rotation round it's Axis in 23 Hours, *Mars* in 24 Hours and 40 Minutes, and *Jupiter* in 9 Hours and 56 Minutes, and if thoſe Planets ſhou'd receive any Inhabitants, and they ſhou'd divide the Time of theſe ſeveral Gyrations into 24 equal Parts, and ſhou'd likewiſe call thoſe Parts Hours, it is manifeſt that in the firſt Inſtance, ſuch Hours wou'd be quicker and ſhorter than ours, and in the third, that they wou'd be more than as ſhort again, and in the ſecond Inſtance, that they wou'd be ſomething longer, and ſlower than thoſe by which we meaſure Duration, and the ſeveral Moments and Inſtants of ſuch Time wou'd be therefore in Proportion vary'd; and yet, it is as evident, that there is no more reaſon to aſſert the Equability of the flux of Time, from the Revolution of the Earth round it's Axis, than from that of *Venus*, or *Mars*, or *Jupiter* about Theirs; from whence it is plain, that real Time or Duration may be Quicker or Slower, according to the Greater or Leſs Celerity of the Moving Body, which we take to compute it by.

Dr. Greg. Aſtron. Prop. 15. Lib. 1. Dr. Keill's Aſtron. p. 37. 96. Edit. 1.

Dr. Gregory's Aſtr. Prop. 30. Lib. 1. Dr. Keill's Aſtron. p. 48, 49. Edit. 1.

Another kind of Moving Bodies, by which we meaſure Time or Duration, are thoſe of Pendulums, whoſe Motions are computed by the Hours or Minutes, which they move in, and which Hours or Minutes are determin'd by the Earth's Revolution about it's Axis.

Succeſſion of Ideas no Meaſure of Duration.

§. 27. As to the Succeſſion of Ideas in our own Minds, that can never give us the leaſt Notion of a uniform Duration at all, much leſs of a uniform Duration, which conſiſts of certain and determin'd Inſtants, becauſe ſometimes we have no ſenſible Succeſſion of our Ideas, as in a Revery, in a Sleep without Dreaming, or when our Minds are fixt upon an Object intently without paſſing to any other; and when the Succeſſion of our Ideas is in the fulleſt Rapidity of them, as in Pleaſure, or in the utmoſt Languor of them as in Pain, we are far from thinking that Time flows Uniformly, ſince the Duration of an Hour in the laſt Caſe is ten Times longer than what we Experience and Imagine it to be in the firſt; It muſt be alſo acknowledg'd, that the Paces of our Ideas are Different in different Perſons, and in the ſame Perſons at different Times; Thus one of a quick and ready Apprehenſion will find his Ideas to move with more Life and Celerity than another, who perceives a kind of Torpor and Dullneſs, which clogs and lies heavy upon his Underſtanding, ſo likewiſe, the ſame Perſon, upon different Circumſtances of his Mind, as he is more Chearful or Debonair, or more Dejected, will proportionably find his Ideas to move with a more or leſs Intenſe Velocity; Beſides which, ſuppoſing a continual and uniform Velocity of our Ideas, ſince yet there is a Succeſſion of them, which is not continu'd and uninterrupted, as Time and Duration is, it will be Impoſſible for diſtinct and ſeparate Ideas, let them follow one another as uniformly, as they will, to give us a Notion of that Time or Duration, which intercedes their Succeſſion.

From all which it is very Evident, that the Succeſſion of our Ideas has nothing to do with the Meaſure of Time or Duration, that it can only inform us, that there is Time or Duration in general, (and which is no more than what Bodies, which are Quieſcent, do) and that it is longer or ſhorter, as it's Ideas move with a greater or leſs Celerity, correſpondent to what we find from Bodies, which are in Motion.

§. 28. Having therefore conſider'd all the Beings, which can poſſibly give us any Notion or Apprehenſion of a Duration or Time, which conſiſts of an uniform Progreſſion of certain and determin'd Inſtants, and ſince there are no Beings that can do it, and ſince we can have no Notion or Apprehenſion of Time or Duration, unleſs from ſome Being, which exiſts, according to §. 23 and 24. it is manifeſt, that a uniform Progreſſion of certain, and fixt, and determin'd Inſtants of Time, is nothing elſe than an abſtracted Idea, and as much ſo, as univerſal and abſtracted Space is, and that therefore thoſe Philoſophers, who proceed upon ſuch Abſtractions, as the preſent Mechanical Philoſophy do's, are not juſtify'd in ſuch Abſtractions, by what we find and Experience in Nature.

Since the uniform Progreſſion of certain, fixt and determin'd Inſtants is not juſtify'd by Nature, it is a Creature of the Mind.

§. 29. Since therefore the Meaſure of Time and Duration is ſo little underſtood by the preſent Philoſophers, even in reſpect of a temporary or finite Duration, and ſince they all of them think in the abſtracted Way of a uniform Progreſſion of certain, fixt and determin'd Inſtants of Time, for which they have no Proof from any thing in Being, it is a little ſurprizing, that ſome Men ſhou'd ſpeak or write ſo poſitively about an Infinity of Duration, when they know nothing of a Finite one, unleſs of an Abſtracted, which, as we have before ſhewn, is not in fact exiſting, and therefore is a Creature of the Imagination only.

If we have not a true Notion of Finite Duration much leſs have we of an Infinite one.

§. 30. It is now Incumbent upon us to ſhew, what the real Meaſure of Time or Duration is, which is ſome real Motion or other, which we obſerve in Nature; For thus we Argue, that if there is any certain Body, which will perform it's Motion in one determin'd Portion of Time, the ſame Body will, we conclude, with all it's Circumſtances continuing the ſame, perform a like Motion in another equal Portion of it, becauſe the Principle and Cauſe ſtill ſubſiſting, without any Variation, muſt of Neceſſity produce the ſame Effect in the ſame Time; from hence it is, that ſince we ſee no Reaſon, why the Earth, in it's Revolution about it's Axis, ſhou'd not be Uniform and Conſtant, and it's ſeveral Revolutions therefore equal to one another, becauſe we do not ſee or know any thing, which ſhou'd diſturb it's Periodical Gyrations, from thence it is, that we take ſuch Revolutions, for our Meaſures of Days, and Hours, and Minutes, and conſequently of Time and Duration, which, whether we Sleep or Wake, and whether our Ideas ſucceed or not, will ſtill be the ſame and unvary'd; and from the Determination of theſe Days, and Hours, and Minutes, we determine the Equation of Time, and know how many of ſuch Minutes are ſpent in the Earths revolving round in the Ecliptick, that is, how many of them belong to the Year; And according to this Meaſure of Duration, a Pendulum, which has 39 Inches and $\frac{1}{5}$ in Length, compleats it's Oſcillation, made up of it's Progreſs and Return, in two Seconds of Time, or in two *60th* Parts of a Minute, which is the *60th* Part of an Hour, and which is the *24th* Part of the Earths Revolution about it's Axis.

How we fix our Meaſure of Time or Duration.

Our Principles of Natural Philoſ. p. 229.

On the contrary, we might take the Oſcillations of Pendulums, upon the Maxim in Philoſophy before mention'd, that Bodies which are in Motion will have equal Effects in equal Times, where the Circumſtances are the ſame, and ſuppoſing the Circumſtances to be the ſame, for a Meaſure of the Earth's Diurnal Revolution.

But yet, in both Caſes, if the Revolutions of the one, or the Oſcillations of the other are not Uniform and Conſtant, our Days, and Hours, and Minutes may be Double or Triple, or in any other Proportion of what we account and eſteem them to be, that is Uniform and Equable, and by conſequence all the Moments and Inſtants of ſuch a Meaſure of Time or Duration wou'd be Double or Triple, or in any other Proportion of what we reckon them.

THUS, ſuppoſing the Earth, in it's Revolution about it's Axis, ſhou'd, in one Part of it, quicken it's Motion, from ſome Cauſes, which are unknown to us, as it certainly do's in it's Revolution about the Sun from Cauſes, which are imagin'd to be known to us, we have divided it's Revolution indeed about it's Axis into 24 equal Hours, upon the Suppoſition of it's Equable Motion, but if that Motion is not Equable, it is plain that the Duration of one Hour is not equal to that of another, but that one may be much longer or ſhorter than another.

AND the ſame may be ſaid in the Oſcillations of Pendulums, in Clocks or Watches, that if the Weight or Spring, by which they move, do's not keep the ſame conſtant Tenor, (which it is impoſſible it ſhou'd do, when it is wound up to the Height, and therefore is more Vigorous and Strong, and when it has not the ſame utmoſt Elaſtick Force, and therefore is more Weak and Languid, and which is ſenſible from the Vibrations, which in the former Caſe are Quicker and Smarter, and in the latter, more Faint and Duller) the Meaſures of Duration, from ſuch Pendulums, will be unequal, and one Minute or Inſtant of it will be different from another, and the ſame, in ſome degree, may be affirm'd of Common Pendulums, which are made to Swing from a Center of Suſpenſion only, Becauſe the Body, which is plac'd in the Center of Oſcillation, cannot have exactly the ſame Force of Gravitation in all the Points of it's Periods, nor the ſame Relation to the Center of Suſpenſion.

Dr. Keill's Aſtronom. De Temporis Æquatione Lect. 26.

FROM all which it is apparent, that Time or Duration muſt be eſteem'd to be quicker or ſlower, as the Body which moves, and which we take for a Meaſure of Duration, is ſo in it's Motion; and ſince the Motion of Pendulums is uncertain, which are the Contrivances of Men, and the Revolution of the Earth about it's Axis, which is the Effect of a Superior Agent, is not ſo, which is confirm'd from the Calculations made of Eclipſes to a Minute, upon the Suppoſition of the Middle or Aſtronomical Days, Hours, and Minutes, which we make uſe of in ſuch Calculations, being Equable, it is likewiſe evident that ſuch a Revolution is only the proper Meaſure of Time or Duration, to which all others will be the moſt juſtly and truly Exacted.

WHAT yet we maintain, is, that the Meaſure of Time or Duration muſt be had from the Motion and Celerity of the Body, which moves, and which we take for the Meaſure of Duration; the Revolution of the Earth round it's Axis is that, by which we compute, and if we had been plac'd in *Venus*, in *Mars*, or in *Jupiter*, ſuppoſing thoſe Planets to be inhabited, and had, as we do here, divided their Revolutions about their Axes into 24 Parts, and had nam'd them Hours, they wou'd, as we before obſerv'd, have been ſhorter or longer than thoſe we now make uſe of, and we might have reduc'd the Revolution of the Earth about it's Axis to ſuch Days, Hours, and Minutes, which thoſe Revolutions preſcribe, with as much Reaſon and Juſtice, as we do now their Revolutions to the Days, Hours, and Minutes, which the Revolution of our Earth has preſcrib'd to them; That is, we take the Revolution of the Earth round it's Axis for the Meaſure of Time or Duration, as being ſuppos'd to be Uniform and Equable in it's Motion, but then the Inſtants and Moments of this Meaſure are no more the proper, peculiar and diſtinguiſhing Meaſure of the Flux of Time or Duration, than any quicker or ſlower Moments or Inſtants are, and if we proceed any farther to abſtract the Moments or Inſtants of Time or Duration from any Celerity, with which they flow, or from the Revolutions of Bodies round their Axes, be they One or Another, we depart from Nature and real Exiſtence, which can only give us a Notion of Duration, and come to Fancies and Chimæra's of our own Minds.

Celerity the Meaſure of Time or Duration.

§. 31. THUS, to ſpeak in general, Real Time or Duration, and not an Abſtracted one, is to be meaſur'd by real Motion, for if the ſame Body moves twice as far, as before, with the ſame Degree of Motion or Force, the Time will be double, in which it moves, if the ſame Body moves as far, as before, with double the Force, it will be in half the time, that is, the Time or Duration, will be as quick and ſhort again in the laſt Caſe, as in the former; and therefore to compute real Time or Duration, as it exiſts in Nature, and according to our Obſervations, without which we cou'd have no Apprehenſion or Notion of it at all, the knowledge of ſome uniform Motion or other muſt be neceſſary to our meaſuring of it, to which uniform Force, which we conſider, whether quicker or ſlower, the Flux of Real Time and Duration, and not an Abſtracted will be Correſpondent, and accordingly Accelerated or Retarded.

From whence it again follows, that the Succeſſion of our Ideas can give us no kind of Meaſure of Duration or Time, unleſs their Force, with which they move or their Celerity is known, and that ſuch Force or Celerity of their Motion, or Succeſſion is Equable and Uniform; and for the ſame Reaſon, the Revolution of the Earth about the Sun in the Ecliptick, or of the Moon about the Earth in the Zodiack, can be no Meaſure of Time or Duration, becauſe they Move unequally in their Orbits, and have different Celerities in different Parts of their Periods, and which Revolutions are therefore reduc'd to Days, and Hours, and Minutes, computed from the Revolution of the Earth round it's Axis, and which cou'd not be known to be unequal, unleſs it was preſum'd that ſuch Days, and Hours, and Minutes were Uniform and Equal; as is Evident from the Doctrine of the Equation of Time before Cited.

Abſtracted Time or Duration no Meaſure of the Real.

§. 32. From the foregoing Sections it is conſequent, that in all the Arguments or Demonſtrations concerning Motion, where an Abſtracted Time is us'd, upon ſuch an Account likewiſe, the Reaſonings will be Abſtracted, and therefore not Anſwerable to Nature, ſince the Meaſure of Time or Duration is originally and previouſly to be aſcertain'd by the Force and Degree of ſome Real, Equable, and Uniform Motion, which is aſſum'd, in order for us to judge of the Periods of Time, and of the Moments or Inſtants, which belong to it.

So likewiſe, if the Time or Duration (which is Correſpondent to, and is the Reſult of one uniform Motion or Celerity) is confounded with that, which anſwers to another, before the one is reduc'd to the other by comparing them together, the Reaſoning, from ſuch a Confuſion of Time into one and the ſame uniform and abſtracted Time, will be wrong and inconcluſive, as if we take the Revolution of the Earth about it's Axis, and divide it's Time or Duration into 24 Parts or Hours, and again the Revolution of *Venus*, *Mars*, or *Jupiter*, about their Axes, and divide their Time or Duration into 24 Parts or Hours, we cannot argue or reaſon upon theſe Times or the Inſtants of them alike, becauſe they are apart Equable, ſince, compar'd with one another, they will be extreamly different, and we muſt reduce the one to the other, before we can ſpeak with any certainty of the Meaſure of Time or Duration, that is, we muſt exact our Notions of Time or Duration to ſome fixt Standard or other of it, to which all others are to ſubmit; and yet that Standard may be the Time or Duration of the Revolution, of one Planet, or another, about it's Axis divided into the ſame Number of Parts, namely of Hours, Minutes, and Moments, which may have different Degrees of Celerity, according to the various Celerities of ſuch Revolutions.

And thus it is in Space, the abſtracted Idea of it is that of one uniform Extenſion, which a Foot, or a Yard, or any other ſtated Length may Meaſure, whereas the Meaſure of Real, and not Abſtracted Space, is the intrinſick or native Force of that Body, which poſſeſſes it, according to what we have ſhewn, in our *Geometry of Solids*, or *of Matter*, and in our *Principles of Philoſophy*; and conſequently, as Time or Duration is meaſur'd by the Force or Celerity of that, which we make our Standard, when that Force or Celerity is finite, be it quicker or ſlower, the Time or Duration is accordingly finite, and is ſhorter or longer; if therefore there is a Being, which has an Infinite Force and Agency, it's Force and Agency muſt be the Meaſure of it's own Duration (thro' all Time) which muſt be likewiſe Infinite, and can be no more adjuſted with a finite Duration, than one finite Duration, whoſe Meaſure is a finite Celerity, can be that of another finite Duration, whoſe Meaſure is a different finite Celerity; What we ſay is, that Time or Space, in the Abſtract, are undefin'd, and are capable of all Quantities, which can be aſſign'd to them.

From what has been hitherto alledg'd from §. 2. to the preſent Section, it enſues, that the firſt Definition in the Mechanical Philoſophy, of Motion's being a continual and ſucceſſive Change of Place, is not true, becauſe it do's not conſider all the Ingredients, which Appertain to Motion, that is, neither what real Motion is, nor what Body or Matter is, nor what real Space or Place is, nor yet what Time or Duration is, all which yet are neceſſary to give us an Idea of a Motion in Nature, and therefore we may conclude, that the firſt Definition of Motion is only a Thing of Abſtraction, and a mere Creature and Imagination of the Mind.

Definition of Celerity Imperfect. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 7. Def. 2.

§. 33. THE Second Definition is that of Celerity, which is ſaid to be an Affection of Motion by which the Body, which is mov'd, paſſes thro' a given Space in a given Time, againſt which there are two Objections.

FIRST, that Motion is introduc'd into this Definition, which was not juſtly defin'd before, according to §. 32. and the preceding ones.

SECOND, that a given Time is ſuppos'd, whereas Time or Duration, by what foregoes, is to be meaſur'd by ſome uniform Motion or Celerity, and therefore Motion or Celerity is not to be meaſur'd by Time, thus the Motion or Celerity of the Earth's Revolution about it's Axis is the Meaſure of Time or Duration to us, and therefore that preciſe Time or Duration is aſcertain'd by that Celerity and Motion, and Time is not previouſly aſſum'd, but determin'd by it; if therefore now there was no Revolution of the Earth about it's Axis, nor any other fixt Meaſure or Standard of Time, the firſt thing, we cou'd do, wou'd be to take a Body, as a Pendulum for Inſtance or any other Body, which from it's Nature we might conclude wou'd, as much as poſſible, deſcribe the Spaces it paſs'd thro' regularly, and with Uniformity; from it's Motion thro' a double Space, we ſhou'd infer there was a double Time, thro' a triple Space, a triple one, and ſo on, and the Time wou'd flow in Proportion to the Motion or Celerity of ſuch a Body; if again we ſhou'd make uſe of a Pendulum, or any other moving Body, which deſcrib'd twice the Space, whilſt the former deſcrib'd only one half of the ſame Space, and we made this latter Celerity our Standard of Duration, it is plain, ſince Time wou'd flow in Proportion to this latter Celerity, it wou'd flow as quick again, as in the former Inſtance, and ſince we might, as it happen'd, make uſe of a quicker, or ſlower Body, in ſuch a Caſe, for our Meaſure of Duration, our Time or Duration wou'd accordingly move quicker, or ſlower.

AND this we more particularly find in Muſick, where the Time is accounted quicker or ſlower, as the Celerity of the Notes is ſo, and the Time, which is kept, and to which they are adjuſted, is meaſur'd by an equable and uniform Pulſation, which yet is no more a proper Meaſure of Time, than any other quicker, or ſlower Pulſation is, than what is us'd on thoſe Occaſions; from all which, and from what has been before ſaid, it appears plain and evident, that a Duration, conſiſting of uniform, certain, and determin'd Inſtants, is an abſtracted Idea, and that the Meaſure of all Duration to us is Celerity and Motion, and which as it is different, Time and Duration is different to us; and the ſame we obſerve in the Succeſſion of our Ideas, for as they move ſwifter or ſlower, Time or Duration appears to us either ſhorter or longer, but yet for the Reaſons above, and upon the Account of what is here ſaid, ſuch a Succeſſion cannot be a fixt Standard of Duration.

How we Meaſure Celerity.

§. 34. SINCE therefore the Celerity of the moving Body is the Meaſure of Time in real Nature, ſo far as our Apprehenſions or Notions of Nature can go, it may be enquir'd, what is the Meaſure of Celerity, which cannot be a uniform or abſtracted Time or Duration, becauſe it ſelf is meaſur'd by ſome certain Celerity or other, whether greater or ſlower is not determin'd, but by a Celerity, whatever it is, which is yet Certain and Uniform; in this Perplexity, what is the Mind's Procedure? namely, to aſſume one kind of Celerity, or Motion, as that of the Revolution of the Earth about it's Axis, which Meaſures out ſo much Time and Duration, which it takes up in the Performance of it's Circuit, and from thence to determine by comparing other Celerities with it, what Proportion of Time or Duration belongs to them, without declaring or knowing, what Time or Duration the Revolution of the Earth round it's Axis takes up, beſides that which it's own Celerity meaſures and aſcertains, and which Time wou'd have a different Fluxion to us, if meaſur'd by a different Celerity, as that of *Venus*, *Mars*, or *Jupiter*'s Revolution about their Axes.

Infinite Time, or Duration an Abſtraction and Creature of the Mind, if an Infinite Being is not prov'd previous to ſuch a Duration.

§. 35. As to an infinite Time or Duration therefore, which proceeds from an abſtracted Notion of it, from all moving Bodies or Celerities whatſoever in Nature, 'tis a pure Metaphyſical Buſineſs, and has no Foundation in the Reality of Things, and all the Arguments, which are form'd upon ſuch an Abſtraction, are Creatures and Fancies of the Mind, in which Philoſophers may, if they pleaſe, indulge themſelves, but without any Advantage to Truth or to Reaſon; for if there were no Being or Exiſtence in the World, there cou'd be no Time or Duration, and if there were no Motion in it, there cou'd be no Meaſure of ſuch Duration, and where that Motion once was not, there was to us no Meaſure of Time, and whatever Meaſure of Time or Duration, we extend beyond it, it is a Supplement made by our own Minds to fill up the vaſt Chaſm, which lies betwixt Eternity and the World's Creating, and thus the *Julian* Period extends it ſelf 730 Years beyond that Time, which can be nothing elſe than a mere Chimæra as to the Meaſure of Time, if there was nothing then Exiſting; it is an Imagination, which can carry it ſelf into Time and Duration, which was not, if there was then no Exiſtence, ſince we have already ſhewn, that Time and Duration is neceſſarily connected with Exiſtence, and cannot be or ſubſiſt in Nature without it.

On the contrary we have ſaid, that Exiſtence and Duration go together, and cannot be ſeparated the one from the other, that an abſtracted Notion of Time or Duration proceeding in uniform Inſtants, which are not meaſur'd by ſome real and moving, and therefore exiſting Force, or other, is a Fancy of the Philoſopher, and not a Thing in Nature, and that all the Arguments upon ſuch Abſtractions are not nor can be juſtified or defended.

And therefore as to infinite Duration, we muſt firſt prove there is an infinite Being, which when we have done from the Works of Nature, and from what we obſerve in the World, (as there is no other way of Proof, excepting that which reſults from a Conviction of the Truth of our Religion) we are from thence to ſhew the Infinity of Duration, that is, from the Infinite Force, Power, and Agency of the Supreme Mover, we are to prove the Infinity of Duration and Time, and not prepoſterouſly from the Infinity of Time or Duration, which lies in our own Romantick Eſtimations and Opinions of it, to prove the Infinite Duration and Eternity of the Supreme Mover; The firſt way is that of a true Philoſophy, and the laſt that of Metaphyſicks and Trifling in the Knowledge of Nature; what we mean is, that a God and Self-exiſting Being, that is a Neceſſary one, muſt be firſt evinc'd, which is eaſily done from a Conſideration of Nature, and then Eternity will follow ſuch a Conviction, but Eternity is not firſt to be preſum'd, and then an Eternal Exiſtence infer'd from it.

The Definition of Reſt is, that it is the Continuance of any Body in the ſame Place, againſt which the ſame Objections lye, as againſt Motion, of it's being only an abſtracted Idea; The remaining Definitions in this Philoſophy, unleſs thoſe which depend upon what we have already examin'd, ſeem to concern only the Explanation of Words, which therefore we omit and ſhall proceed to the Axioms alledg'd.

Dr. Keill's Intr. ad Ver. Phyſ. Lect. 7.

§. 36. The firſt Axiom we ſhall take notice of is, that any Change, ſuperinduc'd to a Natural Body, proceeds from an External Agent, ſince all Matter is unactive, and can produce no Alteration in it ſelf; this therefore depends upon the Inertia of Matter, which has been already conſider'd and refuted.

Axiom the Third. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 8.

§. 37. The next, which we ſhall mention is, that all Matter is of the ſame Nature and has the ſame Eſſential Attributes, whether fluid or hard, *&c.*

The laſt, that the different Forms of Bodies are only different Modifications of the ſame Matter, and depend on the Various Figure, Texture, Poſition, *&c.* of their Parts; both which Axioms have likewiſe been ſufficiently confuted, in the firſt Part of our *Principles of the Modern Philoſophy* examin'd, and in the *Introduction* to the Preſent.

Axioms the Fourteenth and Fifteenth. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 8.

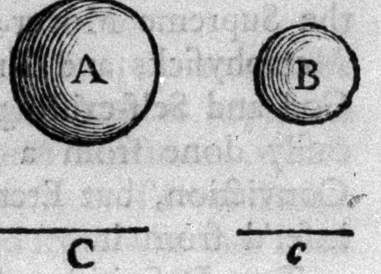
CHAP. III.

Concerning the Principal Theorems of the Mechanical Philoſophy, with a Propoſal of a new Syſteme of Mechanicks.

Theorems which are form'd upon abſtracted Principles, and Notions, of no Service to the Underſtanding of Nature.

§. 1. FROM what has been ſaid concerning the Definitions and Axioms, made uſe of in the Modern Philoſophy, it follows, that if all of them were acknowledg'd and admitted, Since they are abſtracted Ideas, they wou'd be of no greater Service to the Explaining of Nature, and a real Philoſophy, than the Elements of *Euclid,* to the Informing us, what real Extenſion is, as it exiſts in Bodies; for, as in the laſt, if we knew never ſo perfectly, that the Diagonal of a Square is incommenſurate with it's Sides, or that Parallelograms of equal Heights and Baſes are Equal, we ſhou'd not from thence be told, what the Extenſion of Wood was, in Diſtinction to that of Ivory, or Gold, ſo, if, in the firſt, we cou'd demonſtrate a Hundred Theorems concerning Motion, we ſhou'd not, by that, be let into the Knowledge of the real Properties of Motion, in Fire, Air, Water, or perhaps in Mechanicks themſelves, as they are found in Nature, which we ſhall now however more particularly conſider upon the Principles, which have been laid down.

Theorem the Firſt explain'd; That, in the Motions of Bodies, if the Quantities of Matter are Equal, the Moments will be, as the Celerities.
Dr. Keill's Intr. ad Ver. Phyſ. Lect. 9. Dr. Wallis de Motu, Cap. 1. Prop. 22. Part 1. Vol. 1.



§. 2. The Firſt Theorem is, That in comparing the Motions of Bodies, if the Quantities of Matter, in the Bodies which are mov'd, are Equal, the Moments or Quantities of their Motions will be as their Celerities; The Demonſtration of which, without the Ambages here us'd, as in the following Theorems, in ſhort is; Let *A* and *B* be two Bodies, which have equal Quantities of Matter, and let their Celerities be *C* and *c*, the whole Quantity of Motion in *A* is to that in *B*, as *C* to *c*; becauſe, if *A* is = to *B* $AC.Bc::C.c$, or $\frac{AC}{Bc}=\frac{C}{c}$, i. e. $C.c::C.c$, and from whence this Corollary is deriv'd, if $AC.Bc::C.c$, *A* is = to *B*.

The foregoing Theorem conſiders Matter only as a mere Magnitude or Extenſion of Parts.

§. 3. THE foregoing Propoſition, and the Demonſtration of it, is true only upon this Suppoſition, that all Matter is Similar and alike, and that there is nothing in ſuch Similar Matter, excepting it's Magnitude and the mere Number of Parts, for if either Matter is various and different in it's own Nature, or if it has any Properties belonging to it, as Gravity or any other Force whatſoever, tho' we take equal Portions of it, the Moments or Quantities of their Motions will not be, as the Velocities, which are Impreſs'd; But whoever knew any Matter in the whole Univerſe, which only conſiſted in mere Magnitude and the Number of it's Parts? and we might as well take Number and Extenſion, and demonſtrate this Theorem concerning them, ſuppoſing the Units or Parts to be mov'd, as ſuch a Matter, which, what it wou'd ſignify to the Explaining Matter, as it really exiſts in Nature, cannot be eaſily Imagin'd.

Second Theorem explain'd and examin'd; That, in the Motions of Bodies, if the Celerities are Equal, the Moments will be, as the Quantities of Matter.
Dr. Keill's Intr. ad Ver. Phyſ. Lect. 9. Dr. Wallis de Motu, Cap. 1. Prop. 22, &c. Part 1. Vol. 1.

§. 4. THE Second Theorem is, That in the Compariſon of Motions, if the Celerities are Equal, the Quantities of the Motions will be, as the Quantities of Matter in the Bodies, which are mov'd, or, if the Bodies, which are mov'd, are Homogeneous, as their Magnitudes; Let *A* and *B* be unequal, if $C=c$, $AC.Bc::A.B$, or $\frac{AC}{Bc}=\frac{A}{B}$, i. e. $A.B::A.B$; or if *M* and *m* are the Magnitudes, and $A.B::M.m$, it will be $MC.mc::M.m$, and the Corollary is, if $AC.Bc::A.B$, $C=c$. This Demonſtration proceeds, as before, upon the Suppoſition, Firſt, of Matter and a certain Sum of Units or Parts being the ſame, ſo that nothing elſe is conſider'd in Matter, but the Number of Parts or Units in it, Second, that each Part of both Bodies moves no farther, the one than the other, Third, that Homogeneous Bodies and Heterogeneous ones conſiſt of the ſame kind of Matter, tho' differently modify'd.

As to the Firſt Suppoſition, it has been conſider'd in the preceding Theorem; Second, as to each Part of the Body being mov'd, the one as far as the other, that is impoſſible, unleſs we imagine the whole Body as a Point, and then the Quantities of Motion will not be different, but the ſame as their Celerities; if we do not imagine the Bodies, as Points, then the Sum of the Celerities will not be, as the Bodies, which are accelerated, ſince ſuch Celerities will be different, becauſe one Part is really carried farther than another, and therefore it is mov'd with a greater Celerity; ſo that, in the preſent Caſe, it is manifeſt this Philoſophy conſiders not the actual Motions of Bodies, but the Sums of abſtracted Celerities, Independent of the Bodies, which are mov'd, which is an abſtracted Reaſoning, and is of no uſe to the Explaining of Nature, ſeeing the Sums of the Celerities, and of the Parts of Body, are both abſtracted Ideas; Laſtly, as to Homogeneous and Heterogeneous Bodies being the ſame in their Matter, that has been already ſufficiently confuted; not to mention, that where the Sums of the Parts or Units in Body are only conſidered, there can be no real Diſtinction betwixt the Magnitude of a Body, and the Sum of the Parts of that Body, or the Quantity of Matter in it, which yet, in this Theorem, are diſtinguiſh'd.

§. 5. FROM whence it is apparent, that in this Propoſition, and the Demonſtration of it, There are three Things requir'd, the firſt of which is a Suppoſition, which cannot be granted; the ſecond is an Impoſſibility in Nature; and the laſt an Abſurdity, which is That of the Corpuſcular Philoſophy, in which all Matter is preſum'd to be the ſame.

The foregoing Theorem requires more than can be allow'd or granted.

§. 6. A Third Theorem is, That, in the Compariſon of the Motions of Bodies, the Ratio or Proportion of their Moments to each other, is compounded of the Ratio's or Reſpects of their Quantities of Matter and their Celerities. Let A and B the Bodies which are moved be equal or unequal, the Celerities C and c; the Moment of A will be $= AC$, and the Moment of $B = Bc$, or M, m; therefore $M . m :: AC . Bc$, and $\frac{M}{m} = \frac{AC}{Bc} = \frac{A}{B} \times \frac{C}{c}$.

FROM which Theorem, the two former are only Corollaries, for if $A = B$, then will $\frac{AC}{Bc}$ be $= \frac{C}{c}$; if $C = c$, then $\frac{AC}{Bc}$ will be $= \frac{A}{B} = \frac{M}{m}$, as alſo it follows, that if $M = m$, $A . B :: c . C$ or $AC = Bc$, that is, if the Quantities of Matter in the Bodies, which are moved, are reciprocally Proportional to their Celerities, their Moments will be equal.

The Third Theorem explain'd and examin'd; That the Ratio of the Moments of Bodies is compounded of the Ratio's of their Quantities of Matter, and their Celerities.

Dr. Keill's Intr. ad Ver. Phyſ. Lect. 9. Dr. Wallis de Motu, Cap. 1. Prop. 27. Part 1. Vol. 1.

IN all which Demonſtrations, ſince the Sums of the Celerities, and thoſe of the Parts of Matter are only conſider'd, as Sums of Homogeneous Units, multiply'd into each other, it is little more than proving, that 3×4 is $= 12$, or $4 \times 5 = 20$, which Theorems in Arithmetick cannot but be of very conſiderable Importance to the Knowledge of Nature.

§. 7. THE Fourth Theorem is of the like kind with the former, That, in the Compariſon of Motions, the Ratio of the Celerities is compounded of the Direct Reaſon or Proportion of the Moments, or Quantities of Motion, and of the Reciprocal Reaſon or Proportion of the Quantities of Matter.

THAT is, $\frac{AC}{Bc} \times \frac{B}{A} = \frac{C}{c}$, which is manifeſt upon the Principles before preſum'd, and which are here again deny'd, and for the Reaſons alledg'd. The Corollaries of this Theorem are, that $\frac{AC}{A} = C$, and $\frac{Bc}{B} = c$, That is, that the Moments of Bodies, divided by their Matter, are as their Celerities; It may be likewiſe ſaid, by the ſame way of Reaſoning, that the Ratio of the Quantities of Matter is compounded of the Direct Reaſon or Proportion of the Moments or Quantities of Motion, and of the Reciprocal Reaſon or Proportion of the Celerities, that is, $\frac{AC}{Bc} \times \frac{c}{C} = \frac{A}{B}$; alſo $\frac{AC}{C} = A$, and $\frac{Bc}{c} = B$, or the Quantities of Matter are, as the Moments of Bodies divided by their Celerities; all which Demonſtrations admit of the ſame anſwers as were before given.

The Fourth Theorem explain'd and examin'd; That the Ratio of the Celerities is compounded of the Direct Reaſon of the Moments, and of the Reciprocal of the Quantities of Matter.

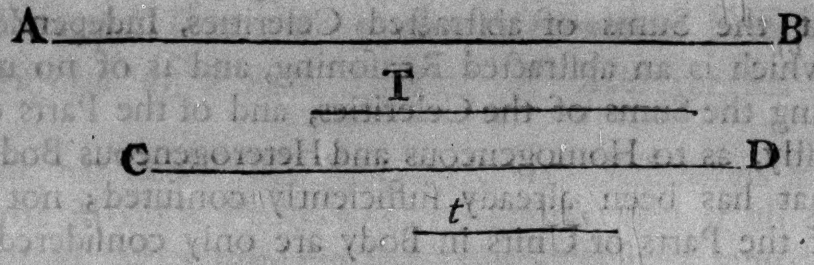
Dr. Keill's Intr. ad Ver. Phyſ. Lect. 9. Dr. Wallis de Motu, Cap. 1. Prop. 27. Part 1. Vol. 1.

§. 8. THE Fifth Theorem is, That if the Celerities of the Bodies, which are moved, are equal, the Spaces, deſcrib'd by them, will be in a Direct Reaſon or Proportion of the Times, in which they are perform'd. Let C, c, repreſent the Celerities, L, l, the Lengths or Spaces, and T, t the Times, if $C = c$, $L . l :: T . t$, and the Corollary is, if $L . l :: T . t$, $C = c$.

Theorem the Fifth explain'd and examin'd; That, if the Celerities of Bodies are Equal, the Spaces deſcrib'd will be in a Direct Reaſon of the Times of their Deſcription.

Dr. Keill's Intr. ad ver. Phyſ. Lect. 9. Dr. Wallis de Motu, Cap. 1. Prop. 23. Part 1. Vol. 1.

Thus let the Body, which is moved, be carried thro the Space AB, in the Time T, and thro' the Space CD, in the Time t, with the ſame Celerity, the Line AB will be to the Line CD, as T to t; becauſe, if the Time T is double or triple of the Time t, it may be divided into 2 or 3 Parts, each of which will be equal to t, and therefore each of the Spaces, which are deſcrib'd in theſe equal Parts of Time, and with the ſame Celerity, will be equal to the Space deſcrib'd in the Time t, and conſequently AB will be to CD, as 2 or 3, to 1, as T is double or triple of t.



Several Things in this Demonſtration taken for granted, which are not prov'd.

§. 9. In this Demonſtration the Matter, which is mov'd, is ſuppoſ'd to have a perfect Inertia, which we have before refuted; the Celerities are preſum'd Equal, which perhaps in Reality cannot be ſaid of any two actual Motions in the Univerſe; the Spaces likewiſe deſcrib'd are nothing elſe but an abſtracted Idea; upon all which Accounts, ſuch a Reaſoning can be of no Service or Import to the Science of Nature: but that which we are at preſent to take notice of is, that the Times of theſe equal Celerities are ſuppoſed Proportional to the Spaces, which ſuch Celerities deſcribe, which was the Thing to be prov'd; for to evidence this, it is ſaid, that if T is the double of t, it will be equal to $2t$, and whatever Space is deſcrib'd in t, there will be a Double deſcrib'd in $2t$; 'tis true, if $1t$ has 1 Length, $2t$ will have 2 Lengths, or *Vice verſâ*, becauſe it is a plain Axiom, but this is ſuppoſing and not proving, for how is it manifeſt, that $1t$ will have 1 Certain and Determin'd Length? if it is anſwer'd, becauſe $2t$ will have 2 Lengths, that is impoſſible, becauſe $2t$ has 2 Lengths upon the Account, that $1t$ has 1 Length; if it is told us $1t$ has 1 Certain Length, becauſe $1t$ has 1 Certain Length, that is affirming what was to be ſhewn; this I ſay, becauſe $1t$ may not only have 1 Determin'd Length, but 2, 3, or a 100 Various Lengths, where the Celerities are the ſame, that is, if the Denſities of the Spaces are different.

Abſtracted Time made uſe of, which yet is determin'd by the Celerity, which Meaſures it.

§. 10. If it is farther alledg'd, that $1t$ muſt have ſome Length or other belonging to it, and $2t$ will have double of that Length, the ſame Celerity continuing, it is ſtill ſuppoſing Time to be a Meaſure of the Celerity, and the Space deſcrib'd by it, that is, it is a Notional Time, which therefore reſts entirely in our own Minds, and is not conformable to Nature, ſince Real Time is the ſame, in it's Meaſure, as the Celerity or the Space deſcrib'd by it, and therefore the Times will be as the Spaces deſcrib'd, and the Spaces deſcrib'd, as the Celerities, or $T.t::L.l::C.c$; for the Real Times, in which any Spaces are perform'd, are commenſurate to thoſe Spaces which are perform'd, but the Spaces which are perform'd, are not commenſurate to an abſtracted Idea of Time, which is made up of Uniform and Unvary'd Points or Moments of it; That is, the Times in which the Celerities are perform'd, are to be meaſur'd by the Celerities which are perform'd, and not the Celerities by the Times (which reſult from them, and are conſequent on them) unleſs that, which is Meaſur'd, can Meaſure; What we Intend is, that Time do's not Conſiſt of any Certain and Determin'd Inſtants, which yet are here ſuppoſ'd, and have been before Confuted.

See Corol. 11. Theorem 5. of the Doctrine of Mechanicks ſubjoin'd.

But that which is ſtill more is, that there may be Celerities ſo perfectly different from what this Philoſophy conſiders, that where the Celerities are Equal, and the Lengths or Spaces Different, the Times may be the ſame, that is, tho' $C=c$, and L greater than l, yet $T=t$, For ſuppoſing AB and CD not to be mere abſtracted Lengths or Spaces, but to be Real ones, and the Firſt to be a more Thin or Diluted, and the Laſt to be more Conſtipated and Denſe, the ſame Celerity or Force will deſcribe the one no ſooner than the other; and in this way of conſidering Extenſion, where $C=c$, L may be to $l::t.T$, which is quite the reverſe of the Proportion aſſign'd by the preſent Theorem, that is, if the Space or Extenſion of CD is ſo much Rarer than it was before, as the Time t is leſs than that of T; ſince in ſuch a Caſe, and upon ſuch a Suppoſition, $TL=tl$; For the ſame Force will deſcribe a leſs Denſe Space in a leſs Time, as it will a more Denſe Space in a Greater.

AND the Advantage of conſidering Extenſion in this Manner, I have already ſhewn in the *Geometry* of *Solids* or of *Matter*, and in which it was propos'd from hence to reduce all Material Beings to Mathematicks, in as full a Senſe, as mere Extenſion now is, nor can it be juſtly deny'd, that we may not as well conſider Lines to be more Denſe or Diluted, as Imagine them to have one Uniform and Abſtracted Extenſion; Eſpecially, if we ſuppoſe thoſe Lines to conſiſt in a more diffus'd or a more compacted Action, which is the Caſe in Nature.

v. Geometria ſolidorum ſive Materiæ.

§. 11. THE Sixth Theorem is, That in the Comparing of Motions, if the Times of the Motions are Equal, the Spaces deſcrib'd will be as the Celerities. That is, if $T = t$, $L.l :: C.c$, and the Corollary is, if $L.l :: C.c$, $T = t$.

THE ſame Anſwer may be given to this Theorem, as to the Former, and farther, that there may be Celerities ſo entirely Different from what this Philoſophy conſiders, that where $T = t$, and C greater than c, yet L may be equal to l, that is, if CD is ſo much Rarer than AB, as the Celerity c is leſs than C; and conſequently L may be $.l :: c.C$, which is the Reverſe of the Proportion aſſign'd in this Theorem, that is, if CD is ſo much Rarer than it was before, as the Celerity c is leſs than that of C.

Theorem the Sixth explain'd and examin'd; That, if the Times are Equal, the Spaces deſcrib'd will be as the Celerities.
Dr. Keill's Intr. ad Ver. Phyſ. Lect. 9.
Dr. Wallis de Motu, Cap. 1. Prop. 23. Part 1. Vol. 1.

§. 12. The Seventh Theorem is, That the Lengths or Spaces perform'd by the Motions of Bodies are in a Ratio compounded of the Ratio's of their Times and their Celerities. That is, $L.l :: TC.tc$, becauſe the Effects L, l will be proportionable to their Cauſes TC, tc. But $\frac{TC}{tc} = \frac{T}{t} \times \frac{C}{c} = \frac{L}{l}$, which was the thing to be prov'd.

FROM this Theorem, the two Former may be deriv'd, as plain and manifeſt Corollaries from it; for ſince $\frac{L}{l} = \frac{TC}{tc}$, If $C = c$, $\frac{L}{l} = \frac{T}{t}$, or $L.l :: T.t$; If $T = t$, $\frac{L}{l} = \frac{C}{c}$, or $L.l :: C.c$. Alſo, if $L = l$, $TC = tc$, or $C.c :: t.T$, that is, if the Spaces or Lengths perform'd are Equal, the Celerities will be reciprocally as the Times.

ALL which Proportions, or Theorems, depend upon the ſame Principles of a Similar and Homogeneous Matter, which is perfectly Paſſive and Unactive, and, in which, nothing elſe is conſider'd, excepting it's Parts, which are imagin'd not to be different from ſo many Abſtracted Units, ſo that Moving Numbers, wou'd as well ſerve the Turn of theſe Demonſtrations, as Moving Bodies.

Theorem the Seventh explain'd; That the Spaces deſcrib'd are in a Ratio compounded of the Ratio's of the Times, and the Celerities.
Dr. Keill's Intr. ad Ver. Phyſ. Lect. 9.
Dr. Wallis de Motu, Cap. 1. Prop. 25. Part 1. Vol. 1.

§. 13. THE Eighth Theorem is, in Comparing of Motions, the Ratio of the Times is Compounded of the Direct Reaſon of the Lengths, and the Reciprocal of the Celerities. For, by the preceding Theorem, $\frac{L}{l} = \frac{TC}{tc}$, multiply both into $\frac{c}{C}$, and $\frac{Lc}{lC} = \frac{TCc}{tcC} = \frac{T}{t} = \frac{L}{l} \times \frac{c}{C}$. And by the ſame way of Reaſoning it may be ſhewn, that the Celerities are in a Direct Reaſon of the Spaces or Lengths, and a Reciprocal of the Times; For $\frac{L}{l} = \frac{TC}{tc}$, by the preceding Theorem, multiply both into $\frac{t}{T}$, and $\frac{Lt}{lT} = \frac{TCt}{tcT} = \frac{C}{c} = \frac{L}{l} \times \frac{t}{T}$.

FROM whence alſo it follows, if $\frac{L}{l} = \frac{TC}{tc}$, Firſt, that $\frac{T}{t} = \frac{Lc}{lC}$, and $T.t :: \frac{L}{C}.\frac{l}{c}$; Namely, the Time is, as the Space perform'd, divided by the Celerity; Second, that $\frac{C}{c} = \frac{Lt}{lT}$, or $C.c :: \frac{L}{T}.\frac{l}{t}$, that is, the Celerity is, as the Space perform'd, divided by the Time; All which Theorems and Proportions terminate, as before, in the ſame Principles, and do not need to be farther conſider'd here.

Theorem the Eighth explain'd; That the Ratio of the Times is compounded of the Direct Reaſon of the Lengths, and the Reciprocal of the Celerities.
Dr. Keill's Intr. ad Ver. Phyſ. Lect. 9.
Dr. Wallis de Motu, Cap. 1. Prop. 25. Part 1. Vol. 1.

§. 14. I have thus far given a ſhorter Demonſtration of theſe Theorems, than is any where Extant, and farther ſhall here ſubjoin a Doctrine of Mechanicks, which has not been yet propos'd by any Philoſophy, and which is Infinitely more Extenſive than the Preſent, as it is alſo more Agreeable to Nature.

THEOREM the Firſt is, That the Ratio of Moments in Bodies Elaſtick, that is, ſo far as they have an Expanſive Force, is compounded of the Reaſons of the Intrinſick or Expanſive Forces of Matter, of the Quantities of thoſe Intrinſick Forces, and, if put into Motion, of their Velocities. Let A and B be Two Bodies, M, m the Mo-

Theorem the Firſt of the New Syſtem explain'd; That the Ratio of Moments of Bodies, which are Elaſtick or Expanſive, is compounded of the Reaſons of the Expanſive

Forces, of the Quantities of thoſe Forces, and of their Velocities.

ments, the Intrinſick or Expanſive Forces E and e, the Quantities or Sums of thoſe Forces A, B, the Velocities V, v. It will be, $M.m::AEV.Bev$, or $\frac{M}{m}=\frac{AEV}{Bev}=\frac{A}{B}\times\frac{E}{e}\times\frac{V}{v}$. For in any Two Bodies, which have an Expanſive Force or a Propenſity to Motion, the Moment of the one muſt be Greater than that of the other, as the Velocity of the one, the Expanſive Force, or Propenſity to Motion, and the Bulk or Magnitude is Greater than That of the other; and therefore, if we Multiply the Expanſive Force into the Magnitude, and both into the Velocity, we ſeem to have the whole Moment of ſuch Bodies in their Motions.

Corol. 1. If therefore $A=B$, That is, if the Sums or Quantities of the Forces are Equal, the Moments will be, as the Intrinſick or Expanſive Forces, multiply'd into the Velocities, or in a Ratio compounded of them, or $M.m::EV.ev$, or $\frac{M}{m}=\frac{E}{e}\times\frac{V}{v}$.

Corol. 2. If $E=e$, which is the Caſe of the Mechanical Philoſophy, in which the Intrinſick or Expanſive Forces are Equal, that is, none at all, the Moments will be in a Ratio compounded of the Quantities, and the Velocities, or $M.m::AV.Bv$, or $\frac{M}{m}=\frac{A}{B}\times\frac{V}{v}$.

Corol. 3. If $V=v$, That is, if the Velocities are Equal, the Moments will be in a Ratio, compounded of the Intrinſick or Expanſive Forces, and the Quantities of them, or $M.m::AE.Be$, or $\frac{M}{m}=\frac{A}{B}\times\frac{E}{e}$.

Corol. 4. If $A=B$ and $E=e$, That is, if the Intrinſick or Expanſive Forces, and their Quantities are Equal, the Moments will be as their Velocities, or $M.m::V.v$, or $\frac{M}{m}=\frac{V}{v}$. This likewiſe is a Theorem in the Mechanical Philoſophy.

Corol. 5. If $A=B$ and $V=v$, That is, if the Sums or Quantities of the Intrinſick or Expanſive Forces, and the Velocities are Equal, the Moments will be as the Intrinſick or Expanſive Forces, or $M.m::E.e$, or $\frac{M}{m}=\frac{E}{e}$.

Corol. 6. If $E=e$ and $V=v$, That is, if the Intrinſick or Expanſive Forces, and Velocities are Equal, the Moments will be, as the Sums or Quantities, of the Intrinſick or Expanſive Forces, or $M.m::A.B$, or $\frac{M}{m}=\frac{A}{B}$. Which is alſo a Proportion affirm'd in the Mechanical Philoſophy.

Corol. 7. If $M=m$, $AEV=Bev$, and $V.v::Be.AE$, i. e. If the Moments are Equal, the Velocities will be in a Reaſon compounded of a Reciprocal, of the Intrinſick, or Expanſive Forces, and the Quantities of them.

Corol. 8. If $M=m$, $AEV=Bev$, and $E.e::Bv.AV$, i. e. If the Moments are Equal, the Intrinſick or Expanſive Forces, will be in a Reaſon compounded of a Reciprocal of the Velocities, and the Quantities of the Intrinſick or Expanſive Forces.

Corol. 9. If $M=m$, $AEV=Bev$, and $A.B::ev.EV$, i. e. If the Moments are Equal, the Quantities of the Intrinſick or Expanſive Forces, will be in a Reaſon compounded of a Reciprocal one of the Velocity, and Intrinſick or Expanſive Forces.

Corol. 10. If $M=m$, and $A=B$, $E.e::v.V$, and $EV=ev$, That is, if the Sums or Quantities of the Intrinſick or Expanſive Forces are Equal, the Intrinſick or Expanſive Force of the Firſt Body, is to that of the Second Reciprocally, as the Velocity of the Second, is to that of the Firſt, and the Moments on both Sides will be Equal.

Corol. 11. If $M=m$, and $E=e$, $A.B::v.V$, and $AV=Bv$, That is, if the Intrinſick or Expanſive Forces are Equal, the Quantities of them are Reciprocally, as their Velocities, and the Moments on both Sides will be Equal, which is another Caſe in the Mechanical Philoſophy.

Corol. 12. If $M=m$, and $V=v$, $A.B::e.E$, and $AE=Be$, That is, if the Velocities are Equal, the Quantities of the Intrinſick or Expanſive Forces are Reciprocally, as the Intrinſick or Expanſive Forces, and the Moments will be Equal.

So that in all the Caſes, which we have mention'd, there are only Four, which the Mechanical Philoſophy conſiders, The Second, Fourth, Sixth, and Eleventh, and theſe only upon the Suppoſition, that E and e are nothing, when they are Equal; As for theſe Intrinſick Forces, we ſhall Reſerve them for a Farther Explanation, and ſhall only at preſent in general name them the Expanſive and Contractive, by the Former of which, Bodies are previouſly diſpos'd to Motion, and are more eaſily put into it by any Impreſſion made, and by the Latter, are oppoſite and averſe to it, and by conſequence, more difficultly obey the like Impreſſions; of the Firſt Kind, are all Elaſtick Bodies, and of the Laſt, all the Groſs and Heavy ones: And when I ſpeak of Forces in Matter, I muſt here declare ſo far againſt the Inertia of it, that I do take upon me to Pronounce Action to be the Subſtratum, and the very Eſſence of it; The denial of which has been the Occaſion of all the Abſurdities in the Corpuſcular Syſtem, and the Reaſon of making ſo ſmall a Progreſs in the accounting for the Phænomenons in Nature. The Expanſive Forces, by which Bodies are more or leſs diſpos'd to Motion, and a Deſcription of Space, are only conſider'd in this Theorem.

Theorem the Second of the New Syſtem explain'd; That the Ratio of the Velocities is compounded of a Direct Reaſon of the Moments, and of a Reciprocal of the Expanſive Forces, and the Quantities of Them.

§. 15. **Theorem** the Second is, That the Ratio of the Velocities is compounded of a Direct Reaſon of the Moments, and of a Reciprocal of the Intrinſick or Expanſive Forces, and the Sums or Quantities of them. For by the preceding Theorem, if M and m are the Moments, $\frac{M}{m} = \frac{AEV}{Bev}$, multiply $\frac{M}{m}$ into Be, and divide it by AE, and $\frac{V}{v} = \frac{MBe}{mAE} = \frac{M}{m} \times \frac{B}{A} \times \frac{e}{E}$. From whence by forming other Equations, other Theorems, or Corollaries may be deduc'd, as in the foregoing.

Theorem the Third of the New Syſtem explain'd; That the Ratio of the Expanſive Forces is compounded of a Direct Reaſon of the Moments, and of a Reciprocal of the Velocities, and of the Quantities of the ſaid Forces.

§. 16. **Theorem** the Third is, That the Ratio of the Intrinſick or Expanſive Forces, is compounded of a Direct Reaſon of the Moments, and of a Reciprocal of the Velocities, and of the Quantities or Sums of the Intrinſick or Expanſive Forces. For $\frac{M}{m} = \frac{AEV}{Bev}$, multiply $\frac{M}{m}$ into Bv, and divide it by AV, and $\frac{E}{e} = \frac{MBv}{mAV} = \frac{M}{m} \times \frac{B}{A} \times \frac{v}{V}$.

Theorem the Fourth of the New Syſtem explain'd; That the Ratio of the Quantities of the Expanſive Forces is compounded of a Direct Reaſon of the Moments, and of a Reciprocal of the ſaid Forces, and of the Velocities.

§. 17. **Theorem** the Fourth is, That the Ratio of the Quantities, or Sums of the Intrinſick or Expanſive Forces, is compounded of a Direct Reaſon of the Moments, and of a Reciprocal of the Intrinſick or Expanſive Forces, and of the Velocities. For $\frac{M}{m} = \frac{AEV}{Bev}$, multiply $\frac{M}{m}$ into ev, and divide it by EV, and $\frac{A}{B} = \frac{Mev}{mEV} = \frac{M}{m} \times \frac{e}{E} \times \frac{v}{V}$. And from theſe a Thouſand Caſes may be offer'd, and Equations form'd upon them, and a great part of Material Nature, in Conjunction with the following Theorems, explain'd by them, if we carefully examine what theſe Intrinſick or Expanſive Forces are, which I ſhall reſerve, as was before ſaid to a farther Expoſition.

Theorem the Fifth of the New Syſtem; That the Spaces deſcrib'd by Two Bodies are in a Ratio compounded of the Reaſons of the Times, the Velocities, the Expanſive Forces, and the Denſities of the Spaces.

§. 18. **Theorem** the Fifth is, That the Spaces deſcrib'd by Two Bodies, which are mov'd, are in a Ratio compounded of the Reaſons of the Times, the Velocities, the Intrinſick or Expanſive Forces, and the Denſities of the Spaces. Let S, s repreſent the Spaces, T, t the Times, E, e the Intrinſick or Expanſive Forces, D, d the Denſities of the Spaces, V, v the Velocities. The Theorem will be, $S . s :: TVED . tved$, or $\frac{S}{s} = \frac{TVED}{tved} = \frac{T}{t} \times \frac{V}{v} \times \frac{E}{e} \times \frac{D}{d}$. For one Space deſcrib'd muſt be Greater than another, as the Time and Velocity, and the Diſpoſition to Motion, or the Expanſive Force, and the Denſity of the Space, which is deſcrib'd, is Greater.

Corol. 1. If $T = t$, $S . s :: VED . ved$, or $\frac{S}{s} = \frac{V}{v} \times \frac{E}{e} \times \frac{D}{d}$, That is, if the Times are Equal, the Spaces deſcrib'd will be in a Direct Reaſon of the Velocities, of the Intrinſick or Expanſive Forces, and the Denſities of thoſe Spaces.

Corol. 2. If $V=v$. $S.s::TED.ted$, or $\frac{S}{s}=\frac{TED}{ted}=\frac{T}{t}\times\frac{E}{e}\times\frac{D}{d}$, That is, if the Velocities are Equal, the Spaces deſcrib'd will be in a Direct Reaſon of the Times, the Intrinſick or Expanſive Forces, and the Denſities of thoſe Spaces.

Corol. 3. If $E=e$, $S.s::TVD.tvd$, or $\frac{S}{s}=\frac{TVD}{tvd}=\frac{T}{t}\times\frac{V}{v}\times\frac{D}{d}$, That is, if the Intrinſick or Expanſive Forces are Equal, the Spaces deſcrib'd will be in a Direct Reaſon of the Times, the Velocities, and the Denſities of thoſe Spaces.

Corol. 4. If $D=d$, $S.s::TVE.tve$, or $\frac{S}{s}=\frac{TVE}{tve}=\frac{T}{t}\times\frac{V}{v}\times\frac{E}{e}$, That is, if the Denſities of the Spaces are Equal, the Spaces deſcrib'd will be in a Direct Reaſon of the Times, the Velocities, and Intrinſick or Expanſive Forces.

Corol. 5. If $T=t$, and $V=v$, $S.s::ED.ed$, or $\frac{S}{s}=\frac{ED}{ed}=\frac{E}{e}\times\frac{D}{d}$, That is, if both the Times, and the Velocities are Equal, the Spaces deſcrib'd are in a Direct Reaſon of the Intrinſick or Expanſive Forces, and the Denſities of thoſe Spaces.

Corol. 6. If $T=t$, and $E=e$, $S.s::VD.vd$, or $\frac{S}{s}=\frac{VD}{vd}=\frac{V}{v}\times\frac{D}{d}$, That is, if the Times, and the Intrinſick or Expanſive Forces are Equal, the Spaces deſcrib'd will be in a Direct Reaſon of the Velocities, and the Denſities of thoſe Spaces.

Corol. 7. If $T=t$, and $D=d$, $S.s::VE.ve$, or $\frac{S}{s}=\frac{VE}{ve}=\frac{V}{v}\times\frac{E}{e}$, That is, if the Times, and the Denſities of the Spaces are Equal, the Spaces deſcrib'd will be in a Direct Reaſon of the Intrinſick or Expanſive Forces, and the Velocities.

Corol. 8. If $V=v$, and $E=e$, $S.s::TD.td$, or $\frac{S}{s}=\frac{TD}{td}=\frac{T}{t}\times\frac{D}{d}$, That is, if the Velocities, and the Intrinſick or Expanſive Forces are Equal, the Spaces deſcrib'd will be in a Direct Reaſon of the Times, and the Denſities of thoſe Spaces.

Corol. 9. If $V=v$, and $D=d$, $S.s::TE.te$, or $\frac{S}{s}=\frac{TE}{te}=\frac{T}{t}\times\frac{E}{e}$, That is, if the Velocities and the Denſities are Equal, the Spaces deſcrib'd will be in a Direct Reaſon of the Times, and the Intrinſick or Expanſive Forces.

Corol. 10. If $E=e$, and $D=d$, $S.s::TV.tv$, or $\frac{S}{s}=\frac{TV}{tv}=\frac{T}{t}\times\frac{V}{v}$, That is, if the Intrinſick or Expanſive Forces, and the Denſities are Equal, the Spaces deſcrib'd will be in a Direct Reaſon of the Times, and the Velocities; which is the only Caſe, which the Preſent Mechanical Philoſophy conſiders, and is the Proportion of Theorem the Seventh in it, which is nothing more than one Corollary of the Ten, already deriv'd from this Fifth Theorem.

Corol. 11. If $T=t$, $V=v$, and $E=e$, $S.s::D.d$, That is, if the Times, the Velocities, and Intrinſick or Expanſive Forces are Equal, the Spaces deſcrib'd will be as the Denſities.

Corol. 12. If $T=t$, $V=v$, $D=d$, $S.s::E.e$, That is, if the Times, the Velocities, and Denſities are Equal, the Spaces deſcrib'd will be as the Intrinſick or Expanſive Forces.

Corol. 13. If $T=t$, $E=e$, $D=d$, $S.s::V.v$, That is, if the Times, the Intrinſick or Expanſive Forces, and Denſities are Equal, the Spaces deſcrib'd will be as the Velocities.

Corol. 14. If $V=v$, $E=e$, $D=d$, $S.s::T.t$, That is, if the Velocities, the Intrinſick or Expanſive Forces, and the Denſities are Equal, the Spaces deſcrib'd will be as the Times. Theſe Two laſt Corollaries are the Fifth and Sixth Theorems of the Mechanical Philoſophy.

Corol. 15. If $S=s$, $TVED=tved$, or $TV.tv::ed.ED$, That is, the Time and Velocity of the Firſt, will be to the Time and Velocity of the Second, as the Intrinſick or Expanſive Force, and Denſity of Space of the Second, is to the Intrinſick or Expanſive Force, and Denſity of Space of the Firſt, and the Spaces deſcrib'd on both Hands will be Equal. As alſo $T.t::ved.VED$, and $V.v::ted.TED$, and $E.e::tvd.TVD$, and $D.d::tve.TVE$.

Corol. 16. If $T=t$, $VE.ve::d.D$, That is, if the Times are Equal, the Velocity, and Intrinſick or Expanſive Force of the Firſt, will be to the Velocity and Intrinſick or Expanſive Force of the Second, as the Denſity of Space of the Second, is to the Denſity of Space of the Firſt, and the Spaces deſcrib'd on both Hands will be Equal.

Corol. 17. If $V=v$, $TE.te::d.D$, That is, if the Velocities are Equal, the Time and Intrinſick or Expanſive Force of the Firſt, will be to the Time and Intrinſick or Expanſive Force of the Second, as the Denſity of Space of the Second, is to the Denſity of Space of the Firſt, and the Spaces deſcrib'd on both Hands will be Equal.

Corol. 18. If $E=e$, $TV.tv::d.D$, That is, if the Intrinſick or Expanſive Forces are Equal, the Time and Velocity of the Firſt, will be to the Time and Velocity of the Second, as the Denſity of Space of the Second, is to the Denſity of Space of the Firſt, and the Spaces on both Hands will be Equal.

Corol. 19. If $D=d$, $TV.tv::e.E$, That is, if the Denſities of the Spaces are Equal, the Time and Velocity of the Firſt, will be to the Time and Velocity of the Second, as the Intrinſick or Expanſive Force of the Second, is to the Intrinſick or Expanſive Force of the Firſt, and the Spaces deſcrib'd on both Hands will be Equal.

Corol. 20. If $T=t$, and $V=v$, $E.e::d.D$, That is, if the Times and Velocities are Equal, the Intrinſick or Expanſive Force of the Firſt, will be to the Intrinſick or Expanſive Force of the Second, as the Denſity of Space of the Second, is to the Denſity of Space of the Firſt, and the Spaces deſcrib'd on both Hands Equal.

Corol. 21. If $T=t$, and $E=e$, $V.v::d.D$, That is, if the Times, and Intrinſick or Expanſive Forces are Equal, the Velocity of the Firſt, will be to the Velocity of the Second, as the Denſity of Space of the Second, is to the Denſity of Space of the Firſt, and the Spaces deſcrib'd on both Hands will be Equal.

Corol. 22. If $T=t$, and $D=d$, $V.v::e.E$, That is, if the Times and Denſities are Equal, the Velocity of the Firſt, will be to the Velocity of the Second, as the Intrinſick or Expanſive Force of the Second, to the Intrinſick or Expanſive Force of the Firſt, and the Spaces on both Hands Equal.

Corol. 23. If $V=v$, and $E=e$, $T.t::d.D$, That is, if the Velocities, and Intrinſick or Expanſive Forces are Equal, the Time of the Firſt, will be to the Time of the Second, as the Denſity of Space of the Second, is to the Denſity of Space of the Firſt, and the Spaces on both Hands will be Equal.

Corol. 24. If $V=v$, and $D=d$, $T.t::e.E$, That is, if the Velocities and Denſities are Equal, the Time of the Firſt, will be to the Time of the Second, as the Intrinſick or Expanſive Force of the Second, is to the Intrinſick or Expanſive of the Firſt, and the Spaces on both Hands Equal.

Corol. 25. If $E=e$, and $D=d$, $T.t::v.V$, That is, if the Intrinſick or Expanſive Forces, and Denſities are Equal, the Time of the Firſt, will be to the Time of the Second, as the Velocity of the Second, is to that of the Firſt, and the Spaces deſcrib'd on both Hands will be Equal, which is the only Caſe, which the Preſent Mechanicks conſiders.

Theorem the Sixth of the New Syſtem; That the Ratio of the Times is compounded of a Direct Reaſon of the Spaces, and a Reciprocal one of the Velocities, the Expanſive Forces, and the Denſities of thoſe Spaces.

§. 19. Theorem the Sixth is, That the Ratio of the Times is compounded of a Direct Reaſon of the Spaces, and of a Reciprocal one of the Velocities, of the Intrinſick or Expanſive Forces, and the Denſities of thoſe Spaces. For, by the foregoing Theorem, $\frac{S}{s}=\frac{TVED}{tved}$, multiply $\frac{S}{s}$ into ved, and divide it by VED, and $\frac{T}{t}=\frac{Sved}{sVED}=\frac{S}{s}\times\frac{v}{V}\times\frac{e}{E}\times\frac{d}{D}$.

Theorem the Seventh of the New Syſtem; That the Ratio of the Velocities is compounded of a Direct Reaſon of the Spaces, and of a Reciprocal one of the Times, the Expanſive Forces, and the Denſities of thoſe Spaces.

§. 20. Theorem the Seventh is, That the Ratio of the Velocities is compounded of a Direct Reaſon of the Spaces, and of a Reciprocal one of the Times, of the Intrinſick or Expanſive Forces, and the Denſities of thoſe Spaces. For, by Theorem the Fifth, $\frac{S}{s}=\frac{TVED}{tved}$, multiply $\frac{S}{s}$ into ted, and divide it by TED, and $\frac{V}{v}=\frac{Sted}{sTED}=\frac{S}{s}\times\frac{t}{T}\times\frac{e}{E}\times\frac{d}{D}$

§. 21.

Theorem the Eighth of the New Syſtem; That the Ratio of the Expanſive Forces is compounded of a Direct Reaſon of the Spaces, and of a Reciprocal one of the Times, the Velocities, and the Denſities of thoſe Spaces.

§. 21. THEOREM the Eighth is, That the Ratio of the Intrinſick or Expanſive Forces is compounded of a Direct Reaſon of the Spaces, and of a Reciprocal one of the Times, of the Velocities, and the Denſities of thoſe Spaces. For, by Theorem the Fifth, $\frac{S}{s} = \frac{TVED}{tved}$, multiply $\frac{S}{s}$ into tvd, and divide it by TVD, and $\frac{E}{e} = \frac{Stvd}{sTVD} = \frac{S}{s} \times \frac{t}{T} \times \frac{v}{V} \times \frac{d}{D}$.

Theorem the Ninth; That the Ratio of the Denſities of the Spaces is compounded of a Direct Reaſon of the Spaces, and of a Reciprocal one of the Times, the Velocities, and the Expanſive Forces.

§. 22. THEOREM the Ninth is, That the Ratio of the Denſities of the Spaces is compounded of a Direct Reaſon of the Spaces, and of a Reciprocal one of the Times, the Velocities, and the Intrinſick or Expanſive Forces. For, by Theorem the Fifth, $\frac{S}{s} = \frac{TVED}{tved}$, multiply $\frac{S}{s}$ into tve, and divide it by TVE, and $\frac{D}{d} = \frac{Stve}{sTVE} = \frac{S}{s} \times \frac{t}{T} \times \frac{v}{V} \times \frac{e}{E}$. Upon which Equations a Multitude of others might be form'd, but I forbear now to Enlarge, and Proceed to thoſe Theorems and Corollaries, which reſpect the Contractive Forces.

WE have here made uſe of Time and Velocity in the ſame way, as has been hitherto done, but as Time is different in it's Flux, according to the Meaſure we make uſe of, and as there may be a Velocity in an Infiniteſimal Space, Equal to a Velocity, which ſhall deſcribe an Infinite one, in a Time given, ſo we, at preſent, abſtract from them, which, if we were to take into the Preſent Theorems, there wou'd be another Compoſition of Forces, namely, by making T and τ to Repreſent the Intrinſick and Real Fluxes of Time, and C, c to Repreſent the Intrinſick Forces of Velocity; Thus, tho' we make uſe of Portions of Time, which flow Equably, yet we do not now determine according to what Meaſure of Celerity they Flow, and tho' we take Velocities, which are meaſur'd by the longer or ſhorter Spaces, which they deſcribe in the ſame Time, we do not conſider thoſe which are different in the ſame Time, and in the ſame Points, or in the ſame Spaces, which they deſcribe, for Example, if all that Force of Velocity, which is ſpent in deſcribing Three Foot, was contracted within the Compaſs of one, every Part of ſuch a Velocity wou'd be very different, from that which we now conſider; If ſuch Times and Velocities therefore were taken into the Computation,

THE Firſt Theorem wou'd be $\frac{M}{m} = \frac{AEVC}{Bevc}$, That is, the Moments of Moving Bodies, wou'd be as their Intrinſick or Expanſive Forces, the Sums of thoſe Forces, their Velocities meaſur'd by the Lengths, which they deſcribe in the ſame Times, and as the Intrinſick or Expanſive Forces of thoſe Velocities, in every Point of the Lengths deſcrib'd by them,

THE Fifth Theorem wou'd be $\frac{S}{s} = \frac{T\tau VCED}{tTvced}$, That is, the Spaces deſcrib'd wou'd be compounded of the Times Directly, and the particular Flux or Celerities of thoſe Times Reciprocally, of the Velocities meaſur'd by the Lengths, which they deſcribe in the ſame Time, and the Intrinſick or Expanſive Forces of thoſe Velocities, in every Point of the Lengths deſcrib'd by them, of the Intrinſick or Expanſive Forces of Matter, and the Denſities of the Space perform'd, Directly. Hitherto we have ſpoke of thoſe Intrinſick Forces only, which we nam'd the Expanſive, we are now come to conſider the Contractive, concerning which the following Theorem may be form'd.

Theorem the Tenth; That the Ratio of Moments of the Expanſive Forces in Heavy Bodies is compounded of the Direct Reaſon of the Velocities, and of a Reciprocal of the Contractive Forces, and of the Sums of thoſe Forces.

§. 23. THEOREM the Tenth is, That the Ratio of Moments of the Expanſive Forces, in Heavy Bodies, is compounded of the Direct Reaſons of the Velocities, and of a Reciprocal of the Intrinſick or Contractive Forces, and of the Sums of thoſe Forces. Let A and B be two Heavy Bodies, M, m the Moments, the Intrinſick or Contractive Forces, C, c, the Quantities, or Sums of thoſe Forces, A and B, the Velocities, V, v; $M . m :: VcB . vCA$, and $\frac{M}{m} = \frac{VcB}{vCA} = \frac{V}{v} \times \frac{c}{C} \times \frac{B}{A}$. That is, one Body will be Quicker and more Expanſive, and in it's Motion, than another, as it's Velocity is Greater, and it's Contractive Force, and the Sum or Quantity of it is Leſs.

Corol. 1. If therefore $A=B$, $\frac{M}{m}=\frac{Vc}{vC}$, and $M.m::Vc.vC$, That is, if the Sums or Quantities of the Intrinſick or Contractive Forces are Equal, the Moments will be in a Ratio, compounded of a Direct one of their Velocities, and a Reciprocal of the Intrinſick or Contractive Forces.

Corol. 2. If $C=c$, $\frac{M}{m}=\frac{VB}{vA}$, and $M.m::VB.vA$, That is, if the Intrinſick or Contractive Forces are Equal, the Moments will be in a Ratio compounded of a Direct one of their Velocities, and a Reciprocal one of the Sums or Quantities of the Intrinſick or Contractive Forces.

Corol. 3. If $V=v$, $\frac{M}{m}=\frac{cB}{CA}$, and $M.m::cB.CA$, That is, if the Velocities are Equal, the Moments will be in a Ratio compounded of a Reciprocal one, both of their Intrinſick or Contractive Forces, and the Quantities of them.

Corol. 4. If $A=B$, and $C=c$, $\frac{M}{m}=\frac{V}{v}$, and $M.m::V.v$, That is, if the Intrinſick or Contractive Forces, and the Quantities of them are Equal, the Moments will be in a Direct Reaſon of the Velocities.

Corol. 5. If $A=B$, and $V=v$, $\frac{M}{m}=\frac{c}{C}$, and $M.m::c.C$, That is, if the Quantities of the Intrinſick or Contractive Forces, and the Velocities are Equal, the Moments will be in a Reciprocal Reaſon of the Intrinſick or Contractive Forces.

Corol. 6. If $C=c$, and $V=v$, $\frac{M}{m}=\frac{B}{A}$, and $M.m::B.A$, That is, if the Intrinſick or Contractive Forces, and the Velocities are Equal, the Moments will be in a Reciprocal Reaſon of the Quantities of the Intrinſick or Contractive Forces.

Corol. 7. If $M=m$, $VcB=vCA$, and $V.v::CA.cB$, That is, if the Moments are Equal, the Velocities will be in a Reaſon compounded of a Direct one, both of the Intrinſick Forces, and the Quantities of them.

Corol. 8. If $M=m$, $VcB=vCA$, and $C.c::VB.vA$, That is, if the Moments are Equal, the Intrinſick or Contractive Forces will be in a Reaſon compounded of a Direct one of the Velocities, and of a Reciprocal of the Quantities of thoſe Forces.

Corol. 9. If $M=m$, $VcB=vCA$, and $A.B::Vc.vC$, That is, if the Moments are Equal, the Quantities of the Intrinſick or Contractive Forces, will be in a Reaſon compounded of a Direct one of the Velocities, and of a Reciprocal of thoſe Forces.

Corol. 10. If $M=m$, and $A=B$, $Vc=vC$, and $V.v::C.c$, That is, if the Moments and the Quantities of the Forces are Equal, the Velocities will be in a Direct Reaſon of the Intrinſick or Contractive Forces.

Corol. 11. If $M=m$, and $C=c$, $VB=vA$, and $V.v::A.B$, That is, if the Moments and the Intrinſick or Contractive Forces are Equal, the Velocities will be in a Direct Reaſon of the Quantities of the Intrinſick or Contractive Forces.

Corol. 12. If $M=m$, and $V=v$, $cB=CA$, and $C.c::B.A$, That is, if the Moments and the Velocities are Equal, the Intrinſick or Contractive Forces will be in a Reciprocal Reaſon of their Quantities.

§. 24. Theorem the Eleventh is, That the Ratio of the Velocities is compounded of a Direct Reaſon of the Moments, the Intrinſick or Contractive Forces, and the Quantities of thoſe Forces. For, by the preceding Theorem, $\frac{M}{m}=\frac{VcB}{vCA}$, therefore $\frac{V}{v}=\frac{MCA}{mcB}=\frac{M}{m}\times\frac{C}{c}\times\frac{A}{B}$. From whence by Forming other Equations, other Theorems, or Corollaries may be deduc'd, as in the Former.

Theorem the Eleventh is, That the Ratio of the Velocities is compounded of a Direct Reaſon of the Moments, the Intrinſick or Contractive Forces, and the Quantities of thoſe Forces.

Theorem the Twelfth of this New Syſtem.

§. 25. **Theorem** the Twelfth is, That the Ratio of the Intrinſick or Contractive Forces, is compounded of a Direct Reaſon of the Velocities, and of a Reciprocal one of the Moments, and of the Quantities of ſuch Intrinſick Forces. For, by Theorem the Tenth, $\frac{M}{m} = \frac{VcB}{vCA}$, therefore $\frac{C}{c} = \frac{VBm}{vAM} = \frac{V}{v} \times \frac{m}{M} \times \frac{B}{A}$.

Theorem the Thirteenth of this New Syſtem.

§. 26. **Theorem** the Thirteenth is, That the Ratio of the Quantities of the Intrinſick or Contractive Forces is compounded of a Direct one of the Velocities, and of a Reciprocal of the Moments and Intrinſick or Contractive Forces. For $\frac{M}{m} = \frac{VcB}{vCA}$, therefore $\frac{A}{B} = \frac{Vmc}{vMC} = \frac{V}{v} \times \frac{m}{M} \times \frac{c}{C}$.

Theorem the Fourteenth is, That the Moments of the Contractive Forces in Bodies, which are Heavy, are in a Reaſon compounded of a Direct one of their Intrinſick or Contractive Forces and of the Quantities of Them, and of a Reciprocal of their Velocities.

§. 27. **Theorem** the Fourteenth is, That the Moments of the Contractive Forces in Bodies, which are Heavy, are in a Reaſon compounded of a Direct one of their Intrinſick or Contractive Forces and of the Quantities of them, and of a Reciprocal of their Velocities, viz. $\frac{M}{m} = \frac{CAv}{cBV} = \frac{C}{c} \times \frac{A}{B} \times \frac{v}{V}$, ſuppoſing C and c, as before, to be the Intrinſick or Contractive Forces.

From whence the ſame Number of Corollaries may be drawn, as in the preceding Theorems of Expanſive Forces,

1. If $C=c$, $M.m::Av.BV$.
2. If $A=B$, $M.m::Cv.cV$.
3. If $V=v$, $M.m::CA.cB$.
4. If $C=c$, and $A=B$, $M.m::v.V$.
5. If $C=c$, and $V=v$, $M.m::A.B$.
6. If $A=B$, and $V=v$, $M.m::C.c$.
7. If $M=m$, $C.c::BV.Av$.
8. If $M=m$, $A.B::cV.Cv$.
9. If $M=m$, $V.v::CA.cB$.
10. If $M=m$, and $C=c$, $A.B::V.v$.
11. If $M=m$, and $A=B$, $C.c::V.v$.
12. If $M=m$, and $V=v$, $C.c::B.A$.

Theorem the Fifteenth of this New Syſtem.

§. 28. **Theorem** the Fifteenth is, That the Moments of the Contractive Forces in Bodies, which are Elaſtick or Expanſive, are in a Reaſon compounded of a Reciprocal one of the Intrinſick or Expanſive Forces, of the Quantities of them, and their Velocities, or $\frac{M}{m} = \frac{Bev}{AEV} = \frac{B}{A} \times \frac{e}{E} \times \frac{v}{V}$. From whence may be deriv'd as many Corollaries as before, which I here omit, ſince the Way is ſhewn, and it is eaſily done.

Theorem the Sixteenth, and which is more General than the Preceding ones.

§. 29. **Theorem** the Sixteenth is, That in General, the Moments of Bodies, where the Expanſive Forces are only conſider'd, may be Varied according to the following Method, for $\frac{M}{m}$ may be Equal to $\frac{A}{B} \times \frac{E}{e} \times \frac{V}{v}$, or $\frac{A}{B} \times \frac{E}{e} \times \frac{v}{V}$, or $\frac{B}{A} \times \frac{E}{e} \times \frac{V}{v}$, or $\frac{A}{B} \times \frac{e}{E} \times \frac{V}{v}$, or $\frac{B}{A} \times \frac{e}{E} \times \frac{V}{v}$, or $\frac{A}{B} \times \frac{e}{E} \times \frac{v}{V}$, or $\frac{B}{A} \times \frac{E}{e} \times \frac{v}{V}$, or $\frac{B}{A} \times \frac{e}{E} \times \frac{v}{V}$, &c.

And the Moments of Bodies, where the Contractive Forces are only conſider'd, will be as follows, $\frac{M}{m} = \frac{A}{B} \times \frac{C}{c} \times \frac{V}{v}$, or $\frac{A}{B} \times \frac{C}{c} \times \frac{v}{V}$, or $\frac{B}{A} \times \frac{C}{c} \times \frac{V}{v}$, or $\frac{A}{B} \times \frac{c}{C} \times \frac{V}{v}$, or $\frac{B}{A} \times \frac{c}{C} \times \frac{v}{V}$, or $\frac{B}{A} \times \frac{c}{C} \times \frac{V}{v}$, or $\frac{A}{B} \times \frac{c}{C} \times \frac{v}{V}$, or $\frac{B}{A} \times \frac{C}{c} \times \frac{v}{V}$, &c. in which Caſes, M is not ſuppos'd Greater than m, as in the Former, but They are left at large to Expreſs the Moments, as they ſhall be determin'd by the Forces, Quantities, and Velocities which compound them, each of which Equations wou'd make a diſtinct Theorem, with a like Number of Corollaries with the Former.

Hitherto we have conſider'd the Expanſive and Contractive Forces ſeparately, but as they may be, and really are united together in all Material Beings whatſoever, the Moments of them will admit of Various and Differing Theorems.

Theorem the Seventeenth is, That the Moments of Bodies, in which the Intrinſick Forces conſiſt of the

§. 30. **Theorem** the Seventeenth is, That the Moments of Bodies, in which the Intrinſick Forces conſiſt of the Expanſive and Contractive, and which are in Motion, as they have hitherto been ſuppos'd, muſt be computed from their Intrinſick Expanſive and Contractive Forces, from the Quantities of them, and from their Velocities.

Expanſive and Contractive, and which are in Motion, muſt be Computed from their Intrinſick Expanſive and Contractive Forces, from the Quantities of them and their Velocities.

Therefore Bodies endu'd with ſuch Forces, have their Moments compounded of all of them, That is, $\frac{M}{m}$ may be Equal to $\frac{AECV}{Becv} = \frac{A}{B} \times \frac{E}{e} \times \frac{C}{c} \times \frac{V}{v}$, or $\frac{AECv}{BecV} = \frac{A}{B} \times \frac{E}{e} \times \frac{C}{c} \times \frac{v}{V}$, or $\frac{AEcV}{BeCv} = \frac{A}{B} \times \frac{E}{e} \times \frac{c}{C} \times \frac{V}{v}$, or $\frac{AeCV}{BEcv} = \frac{A}{B} \times \frac{e}{E} \times \frac{C}{c} \times \frac{V}{v}$, or $\frac{BECV}{Aecv} = \frac{B}{A} \times \frac{E}{e} \times \frac{C}{c} \times \frac{V}{v}$, or $\frac{AEcv}{BeCV} = \frac{A}{B} \times \frac{E}{e} \times \frac{c}{C} \times \frac{v}{V}$, or $\frac{AecV}{BECv} = \frac{A}{B} \times \frac{e}{E} \times \frac{c}{C} \times \frac{V}{v}$, or $\frac{BeCV}{AEcv} = \frac{B}{A} \times \frac{e}{E} \times \frac{C}{c} \times \frac{V}{v}$, or $\frac{Aecv}{BECV} = \frac{A}{B} \times \frac{e}{E} \times \frac{c}{C} \times \frac{v}{V}$, or $\frac{BecV}{AECv} = \frac{B}{A} \times \frac{e}{E} \times \frac{c}{C} \times \frac{V}{v}$, or $\frac{Becv}{AECV} = \frac{B}{A} \times \frac{e}{E} \times \frac{c}{C} \times \frac{v}{V}$, or $\frac{BeCv}{AEcV} = \frac{B}{A} \times \frac{e}{E} \times \frac{C}{c} \times \frac{v}{V}$, or $\frac{BEcv}{AeCV} = \frac{B}{A} \times \frac{E}{e} \times \frac{c}{C} \times \frac{v}{V}$, or $\frac{BECv}{AecV} = \frac{B}{A} \times \frac{E}{e} \times \frac{C}{c} \times \frac{v}{V}$, &c. Each of theſe Equations is a diſtinct Theorem, and has a like Number of Corollaries with Theorem the Fifth; Which is a manifeſt Conviction of the wonderful Extenſiveneſs of this Doctrine.

And here again likewiſe M is not ſuppos'd Greater than m, but they are meant to Expreſs the Compoſition of Forces, in their Compariſon with one another, whatever ſuch Compoſition may be. Whenever we find the Quantities Inverted, the Theorems and Corollaries are much the ſame.

Theorem the Eighteenth is, That the Ratio of Spaces deſcrib'd by Bodies, which have an Expanſive and Contractive Force, may be differently compounded of the Expanſive and Contractive Forces, of their Velocities, of the Times, and the Denſities of Spaces.

§. 31. Theorem the Eighteenth is, That the Ratio of Spaces deſcrib'd by Bodies, which have an Expanſive and Contractive Force, may be differently compounded of the Expanſive and Contractive Forces, of their Velocities, of the Times, and the Denſities of Spaces; Each of which will obtain an Influence in Determining the Proportion of them: Thus, $\frac{S}{s} = \frac{ECVDT}{ecvdt}$, or $\frac{ECVDt}{ecvdT}$, or $\frac{ECVdT}{ecvDt}$, or $\frac{ECvDT}{ecVdt}$, or $\frac{EcVDT}{eCvdt}$, or $\frac{eCVDT}{Ecvdt}$, or $\frac{ECVdt}{ecvDT}$, or $\frac{ECvdT}{ecVDt}$, or $\frac{EcvDT}{eCVdt}$, or $\frac{ecVDT}{ECvdt}$, or $\frac{ECvdt}{ecVDT}$, or $\frac{EcvdT}{eCVDt}$, or $\frac{ecvDT}{ECVdt}$, or $\frac{eCVdt}{EcvDT}$, or $\frac{eCvdT}{EcVDt}$, or $\frac{eCvDt}{EcVdT}$, or $\frac{ecVdT}{ECvDt}$, or $\frac{ecvdT}{ECVDt}$, or $\frac{ecvDt}{ECVdT}$, or $\frac{Ecvdt}{eCVDT}$, or $\frac{ecvdt}{ECVDT}$, &c. That is, by all the Various Ways, by which theſe Forces, Times, Velocities, and Denſities can be poſſibly combin'd, there will be different Spaces, and S, s, will be greater or leſs, according to ſuch Combinations; each of theſe will alſo ſupply us with ſo many new Theorems, and the Corollaries conſequent upon them; and wherever we find the Quantities Inverted, the Theorems and Corollaries will be much the ſame.

We have thus far ſuppos'd theſe Intrinſick Forces, and the Quantities of them to be in Motion, and endu'd with a certain Velocity, to ſhew the preſent Mechanical Philoſophy, how Short and Defective it is in giving us an Account of the Real Motions of Bodies, and at the ſame time, to explain in ſome Sort, the Notion we have of the Expanſive and Contractive Forces, in Compariſon with Velocity, the Former of which we make to concur with Velocity, and the Latter to act Counter to it, and with Gravity; So that, As Impreſs'd Velocity is a Force directly contrary to Gravity, as is not only manifeſt, from projecting a Body Perpendicularly upwards, from the Horizon or Parallel to it, or in any other Inclination, but even Perpendicularly downwards, Since, by how much, it is accelerated by the Velocity impreſs'd, by ſo much it is hindred from producing it's own proper Effect; So Poſitive Reſt, which is oppoſite to Velocity, is Poſitive Gravitation; Suitable to theſe Forces of Velocity and Gravitation, which are Obſervable in Material Beings, which Gravitate and Move, are thoſe which I call the Intrinſick Expanſive, and Contractive Forces, in Bodies, Diſtinct from ſuch Velocity or Gravitation, by which in their own Nature with which they were originally endow'd, they obtain theſe two Qualities of Expanſion, or as much as poſſible dilating themſelves, and by which they ſhew a conſtant Conatus of Receding from the Centres of their Actions, whilſt, by another Force of Contraction, they are Compreſs'd and Condens'd towards them; And from a various Mixture of a greater or leſs Proportion of theſe Forces, all the Qualities of Bodies ariſe, as we ſhall ſhew in the Preſent and following Chapters, and that they wou'd preſerve theſe Forces, tho' they were ſet in the midſt of an Infinite Space, without any other Bodies, as the Earth or Sun to affect them; Inſomuch, that if the Earth, or any other Planet, were plac'd at an Immenſe Diſtance from all other Bodies, it wou'd remain fixt and immoveable, and if Put into Motion, it wou'd not continue that Motion in Infinitum, but wou'd return to it's Reſt by it's own Contractive Force, when that Impreſs'd Velocity was ſpent; as the Sun continues in it's Station by it's Expanſive.

SINCE therefore we reckon ſo much depends upon theſe Intrinſick Forces, in accounting for Nature, we ſhall now give the Theory of them ſeparate from Velocity, in Conjunction with which they were before conſider'd.

Theorem the Nineteenth is, That the Moments of Bodies, a-part from the Quantities or Velocities of Them, conſiſt of their Expanſive and Contractive Forces.

§. 32. THEOREM the Nineteenth is, That the Moments of Bodies, a-part from the Quantities or Velocities of them, conſiſt of their Expanſive and Contractive Forces, $\frac{M}{m} = \frac{EC}{ec}$, or $\frac{Ec}{eC}$, or $\frac{eC}{Ec}$, or $\frac{ec}{EC}$.

Caſ. 1. If $\frac{M}{m} = \frac{EC}{ec}$, i. e. If the Moments of Bodies are Equal to a Direct Reaſon of the Expanſive Force, to the Expanſive, and of the Contractive, to the Contractive, i. e. If they are as the greateſt Expanſive Force, into the greateſt Contractive Force, to the leaſt Expanſive Force, into the leaſt Contractive, it will probably be the Caſe of Gold, which has the greateſt Contractive by it's Weight, and the greateſt Expanſive by it's Colour, which comes the neareſt to that of the Suns, which has an entirely Expanſive Force, as that of Fire and Flame has, and of black Aſhes or Dirt, which has the leaſt Contractive and Expanſive, by it's Weight and it's Colour: And from this Theorem, ſeveral Years ago, I had an Opinion, that if to the Weight of Quick-Silver or Mercury, there cou'd be communicated by Fire the Expanſion of it, Gold might be made; But whilſt you endeavour to impart the Expanſiveneſs of Fire or Flame, to the Weight or Contractive Force of Mercury, you diſſipate the one without communicating the other; On the contrary, this is Effectually done in Nature by the Sun's, or the Subterraneous Heats continual Influence upon the ſame Mineral, where the Expanſive Force of the Former, is not ſo violent, as to diſſolve the Contractive of the Latter, but adds it's Expanſive to it.

I try'd, at that Time, to obviate this Difficulty, and, as it appear'd to me, by Rational Methods enough, namely, by encloſing the Mercury, ſo as it ſhou'd not, if poſſible, be able to evaporate, to wit, in a Strong, Thick, Iron Shell, and putting all thoſe Ingredients to it, which might, as I imagin'd, contribute to the Effect deſir'd, and which was plac'd in a large Fire, and made Red-Hot; upon opening the Iron Shell the Mercury had forc'd it's Way thro', but had left a ruddy Dew or Powder upon the outmoſt Sides of it; and I yet do not Queſtion, but Gold might be made, if we cou'd communicate Gradually the Expanſive Force of Fire to the Weight of Mercury, which by ſo many Degrees, as it was communicated, wou'd likewiſe by ſo many Degrees increaſe the Weight or Contractive Force of it, becauſe, as it ſeems, no Expanſive Force can prevail, the Contractive continuing, till it has made Room for it ſelf, that is, by condenſing the Contractive or Exciting it to Exert it's own Force in Oppoſition to it, and thereby Making it unite the Cloſer; and which in all Probability is the Reaſon, why ſeveral Heavy Bodies, as Lead, receive an Addition to their Weight by being Calcin'd, whilſt others, as Bones, Wood, Coal, *&c.* which are of a Lighter Nature, and have a more Expanſive Force find a Diminution of it, becauſe the Contractive is increas'd, in the former Caſe, by being Excited, and the Expanſive, not being able to Diſſipate it, lodges it ſelf in it, which gives the Red-Colour, which is again chang'd to a White by a Contractive Force, as Vinegar; and, in the latter, the Expanſive is increas'd by a Diſſolution of the Contractive, and an Addition to the Expanſive.

THE Experiment I have mention'd, I ſuppoſe, is ſomething Dangerous to be try'd, in Caſe the Shell ſhou'd burſt, by the Expanſion of the Quick-Silver, tho' I did not find any ſuch Effect; But if it were made by a more Gradual, and by a Quick and Conſtant Fire, as that of Charcoal, and not too Violent, or by a Sand-Heat, it is not Impoſſible but it might ſucceed better. As to the preſent Theorem, it extends to all other Bodies, which have intermediate Degrees of the Expanſive and Contractive Forces, betwixt the Greateſt and Leaſt, and which are in the Direct Proportion here aſſign'd of the Expanſive to the Expanſive, and of the Contractive to the Contractive.

I ſhall here add, what I find Written, many Years ago, in ſome Looſe Papers, but will not Vouch the Certainty of the Experiment, becauſe I have not ſince then try'd it, and perhaps there may be ſome Miſtake in it, but this I find, that on *Friday* the *16th* of *October*, the Year is not nam'd, I pour'd out two or three Drops of Quick-Silver into a Copper Veſſel, and laid upon it thrice the Quantity of Antimony Powder'd, then pour'd upon it ſome Lime-Water, with a little Lime, and cover'd it with ſmall Gravel Stones infus'd in Brine, and there ris' a Yellow Ductile Metal not unlike Gold; I alſo made ſeveral other Experiments, as I perceive by thoſe Papers, with the ſame Intention of Imparting the Expanſive Force of Fire, or Flame, or Heat to Quick-Silver, and of fixing, and increaſing it's Contractive, and tho' I did not Succeed, I had the Pleaſure of Thinking, it was not Impoſſible but I might, and little elſe, as I well Remember, ran in my Thoughts for ſome Time, but Building of Theaters, and Raiſing of Colleges and Chappels, and other Noble and Magnificent Structures, till the Golden Dream at length vaniſh'd, and left me juſt as Rich, as it found me.

Corol. 1. If $E=e$, $M.m::C.c$, i. e. The Moment of one Body will be to that of another, as the Contractive Force of the one is to that of the other, which is the Caſe of Heavy Bodies, and whoſe Expanſive or Contrary Force is Equal; Thus if Quick-Silver and Water have an Equal Degree of being thrown into Fumes or Expanſiveneſs, Velocity or Volatility, they will be as their Contractive Forces, which are Analogous to their Forces of poſitive Reſt or Gravitation; and the ſame may be ſaid of all other Bodies, where their Inclinations and Propenſities to Expanſion are Equal, and their Inclinations and Propenſities to poſitive Reſt or Gravitation different.

Corol. 2. If $C=c$, $M.m::E.e$, i. e. If the Contractive Forces are Equal, the Moments of Bodies will be in a Direct Reaſon of the Expanſive Forces; The Bodies, which have the leaſt Contractive Force, and the greateſt Expanſive, are thoſe of the Sun, and of Common Fire and Flame, which if their Contractive Forces are Equal, will be in a Direct Reaſon of their Expanſive, and one will be ſo much Hotter, and more Vivid and Strong in it's Action than the other, as it's Expanſive Force is greater; All lively and volatile Bodies, ſo far as they are ſo, come under this Corollary, as all Groſſer and more Heavy ones, ſo far as they are ſuch, under the Former.

Corol. 3. If $M=m$, $EC=ec$, and $E.e::c.C$, i. e. as the Expanſive Force of one Body is to that of the other, ſo the Contractive of the Latter, is to that of the Former, or a greater Expanſive Force into a leſſer Contractive, will be Equal to a leſſer Expanſive Force into a greater Contractive.

THUS Gun-Powder, which has a vaſt Expanſive Force, and but a ſmall Contractive one, is Equal in it's Moment to whole Tuns in Weight, which have a great Degree of the Contractive Force, and but a ſmall one of the Expanſive.

Caſ. 2. If $\frac{M}{m}=\frac{Ec}{eC}$, The Moments of Bodies, in Reſpect of their Intrinſick Forces, will be in a Direct one of the Expanſive, and a Reciprocal of the Contractive; i. e. $M.m::Ec.eC$, or the Moments of the Intrinſick Forces, in ſuch a Caſe, are as the greateſt Expanſive Force multiply'd into the leaſt Contractive, to the leaſt Expanſive into the greateſt Contractive, and ſo of any intermediate Degrees of theſe Forces, where they hold the ſame Reciprocal Proportion, that is, as the Moment of Fire to that of Lead, or of Air to Earth, *&c.*

Corol. 1. If $E=e$, $M.m::c.C$, i. e. The Moments of Bodies will be Reciprocally as their Contractive Forces, or a leſſer Moment into a greater Contractive Force, is Equal to a greater Moment into a leſs Contractive; Thus a leſſer Portion of Lead, will be Equal in it's Moment, to a greater of Iron.

Corol. 2. If $C=c$, $M.m::E.e$, i. e. The Moments will be in a Direct Reaſon of the Expanſive Forces, according to *Corol.* 2. *Caſ.* 1.

Corol. 3. If $M=m$, $Ec=eC$, or $E.e::C.c$, i. e. The Expanſive Force of the firſt Body, will be to the Expanſive of the Second, as the Contractive of the Second, to the Contractive of the Firſt, which may be the Caſe of Gun-Powder and Heavy Bodies, for if we multiply the greateſt Expanſive Force into the leaſt Contractive, it will be Equal to the greateſt Contractive into the leaſt Expanſive, which is the Caſe before, in *Corol.* 3. *Caſ.* 1. of Gun-Powder and Heavy Bodies.

Caſ. 3. If $\frac{M}{m} = \frac{eC}{Ec}$, The Moments will be in a Direct Reaſon of the Contractive Forces, and in a Reciprocal one of the Expanſive, or $M.m::eC.Ec$, which is that of Lead to Fire, or Earth to Air, *&c.* The Corollaries are much the ſame with the Former.

Caſ. 4. If $\frac{M}{m} = \frac{ec}{EC}$, The Moments will be in a Reciprocal Reaſon of the Expanſive and Contractive Forces, that is, as the leaſt Expanſive to the greateſt Expanſive, and the leaſt Contractive to the greateſt Contractive, which may be the Caſe of Black Dirt or Aſhes to Gold.

And the Corollaries are much the ſame with thoſe of *Caſ.* 1. ſo that all theſe Four Caſes are ultimately Reducible to the Firſt and Second, and Bodies, compar'd with one another, will be either thoſe which have a greater Expanſive or Contractive Force, in Reſpect of others, which have a leſs; or elſe thoſe, which have a greater Expanſive, and a leſs Contractive, in Reſpect of others, which have a leſs Expanſive, and a greater Contractive.

From the Various and Infinite Mixtures and Combinations of theſe Forces in differing Proportions, all the ſeveral Forms and Species of Material Beings ſeem to ariſe, and which will much better ſolve, as we ſhall afterwards ſhew, the apparent Properties and Qualities of Bodies, than the Imaginary Figures and Textures of Parts, introduc'd by the Corpuſcular Syſtem, for that Purpoſe and End; That there are ſuch Forces in Material Beings is very Evident, ſince ſome have a greater Diſpoſition to Motion, Velocity, and Expanſion, which I call the Expanſive Force, and others to Reſt, and to what is Contrary to Action or Motion, Velocity and Expanſion, which I call the Contractive: The firſt is ſeen in Fiery, Luminous, Volatile, Light, and Elaſtick Bodies; and the laſt in Groſs, Heavy, Viſcous, Torpid and Dull ones.

That theſe Forces likewiſe Exiſt together, and in Conjunction, is manifeſt from all the firſt Kind, having Gravity, and from all the laſt, having Colour, and a Capacity of being mov'd, which we ſhall farther Explain in the following Chapter; After having Premis'd, that we make all the World to be full of an Ethereal Matter, Quick, Subtle, and Elaſtick, which is capable of communicating the leaſt Impreſſions or Actions of Bodies to our Organs of Senſation, and by which our Souls, from the Mediation of thoſe Organs, become united to all the Beings which ſurround us.

That a Vacuum has not been prov'd by any Philoſophers, I have already evinc'd, from their ſuppoſing Matter to be Similar and Homogeneous, in Order to ſuch a Demonſtration; I have alſo ſhewn, that ſuch a Similar and Homogeneous Matter is a mere Hypotheſis of the Mind, and wholly Incapable of ſolving any one Appearance we can name, or any one Quality of that Matter, which it is aſſum'd and taken to Account for; On the contrary, we propoſe from theſe Intrinſick Forces in Matter, and from an Univerſal Action in all Nature, thro' the vaſt Expanſe of it, and which Forces and Action we can Evidence, muſt be deriv'd from an Infinite and All-wiſe Agent, we propoſe, I ſay, from them to Explain, the Various Phænomenons which occur to us, and which we are fully ſatisfied may be better and more Rationally done, than from fanciful and humorous Abſtractions of a void Space, of a mere Length, Breadth, and Thickneſs, and of an Hypothetick, Extended, Solid, Diviſible, and Moveable Matter, without one Real Force belonging to it.

In the foregoing Theorems, we have made the Compoſition of Forces to conſiſt in the Multiplication of Them into each Other, tho' Nature may poſſibly, in uniteing of various Forces together, draw out other Effects from ſuch Compoſitions, than what will reſult from a bare Multiplication of Them, to aſcertain which, the Genius and Temper of the Expanſive and Contractive are to be Inquir'd into, and what follows from their Mixture or Union.

CHAP.

CHAP. IV.

Concerning the Five Mechanical Powers, and the Demonſtrations of Them.

Gravity Inquir'd into, as it reſpects the Mechanical Philoſophy. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 10. Theorem 9. Dr. Wallis de Motu, Cap. 1. Prop. 13. Part 1. Vol. 1. Sir Iſ. Newt. Princ. Def. 8. Lib. 1. & Prop. 7. Lib. 3.

§. 1. HAVING conſider'd Matter as an Unactive Being, and the Theory from thence of Motion, and the ſeveral Circumſtances, which enter into it, as Space, Time, and Celerity, we are now to Examine into another Property of Matter, namely, it's Gravity or Weight; the Laws of which this Philoſophy endeavours to eſtabliſh, and from them to account for the Mechanick Powers, which are imagin'd to be ſolv'd by them: The firſt Theorem in this Doctrine is, that the Weights of all ſenſible Bodies, near the Superficies of the Earth, are Proportional to the Quantities of Matter contain'd in them.

The Notion of Matters, being Proportional to it's Weight already confuted.

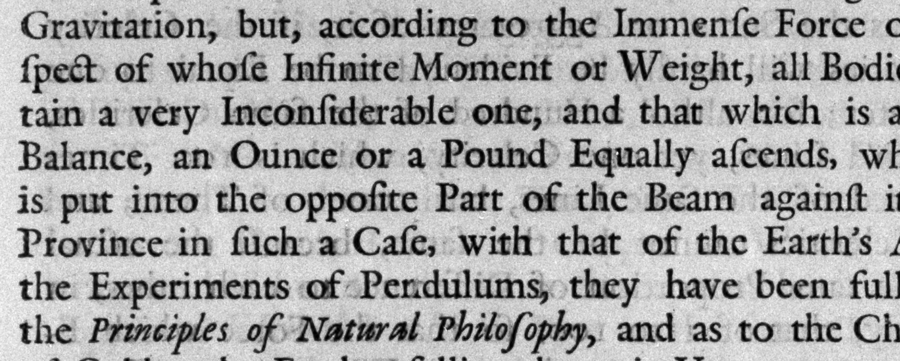
§. 2. We have abundantly, as we hope, confuted this Notion in our firſt Part of the Modern Philoſophy examin'd, and therefore it might be needleſs to give a particular Anſwer to it's being aſſerted here; however, ſince the only Reaſon aſſign'd for the Truth of this Theorem is, that the Bodies by the Force of their Gravitation falling downwards (if we take off or allow for the Reſiſtance of the Air) deſcribe Equal Spaces in the ſame Times, which is ſaid to be Evident from ſeveral Experiments made with Pendulums, ſince this is the only Reaſon aſſign'd, we ſhall not think much to conſider the Validity of it.

Why Matter is not really Proportional to it's Weight farther ſhewn.

§. 3. That therefore this is no good Argument is evident, becauſe near the Earth it is impoſſible Bodies ſhou'd Gravitate according to their own Intrinſick Force of Gravitation, but, according to the Immenſe Force of Attraction in the Earth, in Reſpect of whoſe Infinite Moment or Weight, all Bodies, which deſcend to it, muſt obtain a very Inconſiderable one, and that which is altogether Inſenſible; juſt as in a Balance, an Ounce or a Pound Equally aſcends, where a Million Weight or a Tun is put into the oppoſite Part of the Beam againſt it, and which performs the ſame Province in ſuch a Caſe, with that of the Earth's Attraction in the Former; As to the Experiments of Pendulums, they have been fully conſider'd in the firſt Part of the *Principles of Natural Philoſophy*, and as to the Chief Experiment, beſides, of a Piece of Gold, and a Feather falling down in Vacuo at once, it is not yet prov'd, that ſuch a Heavy Body, as Gold, and ſo Light a one, as a Feather, may not have the ſame Effect, when ſet together, as all other Bodies have, of being Obedient to, and following the Action of the Stronger; it is not yet ſhewn, that the Gravity of the Gold may not carry the Feather along with it, by it's Superior Influence and Action; or if not, it is not yet evinc'd, nor ever will be, that the Matter is of the ſame Sort in the Gold, as in the Feather, if it is not, Matter will not be proportional to it's Weight, but different Kinds of Matter will Gravitate alike, and therefore the ſame Kind of Matter will Gravitate differently, contrary to this Hypotheſis.

Problem the Firſt explain'd and examin'd. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 10.

§. 4. The next Thing propos'd in this Philoſophy is, to find the Velocity, with which a Body given is to be mov'd, ſo that it may have a Moment, or Quantity of Motion, Equal to any Moment given. Let the Body given, be *A*, whoſe Moment, or whole Quantity of Motion, ought to be Equal to the Moment of *B*, mov'd with the Celerity *c*; let it therefore be, *A . B* :: the Celerity *c*, to another Celerity *C*, which will be the Velocity enquir'd or ſought, namely, that, with which, if *A* is mov'd, it's Moment will be Equal to the Moment of *B*, as is evident from what goes before; ſince the Moments of Bodies are Equal, if their Celerities are Reciprocally Proportional to thoſe Bodies; but by the Hypotheſis *c . C* :: *A . B*, from whence the Moment of *A* will be = to the Moment of *B*, or $CA = cB$, which was to be found.



§. 5. But

This Demonſtration proceeds upon Matter being conſider'd, as entirely unactive, and conſiſting only of mere Magnitude.

§. 5. But it is evident, that this Demonſtration proceeds upon Matter's being perfectly unactive, excepting as Motion or Celerity is impreſs'd upon it, that Matter, conſider'd in it's ſelf, is nothing but Bulk or Magnitude, without any other Properties belonging to it, and therefore, the Moment of a Body is no other than a Sum of Celerities, which are counted up and computed by the Number of Points in the Magnitude, and if ſo, we may throw Matter entirely out of the Queſtion, and only conſider a Globe of Space, according to whoſe Dimenſions we may aſcertain the Moment of the Celerities; for ſince this Philoſophy takes Matter to be nothing in it's ſelf, the Demonſtration will amount to this, that 100 Equal Celerities, for Inſtance, are the ſame as 1 Celerity, which is 100 Times greater than the Former, which abſtracted Axiom, ſuppoſing it to be one, can be of no more Importance, in the Explaining of Nature, than that of 100 Lines, which are plac'd Parallel to each other, as in the firſt Caſe, being = to 100 of the ſame Lines plac'd in Directum, as in the Latter, or that of 100 being Equal to it's ſelf; but can any one argue, that, becauſe 3 is = 3, or 100 to 100, in the Abſtract, therefore the Body or Corporeal Subſtance $A \times C$ the Celerity is Equal to B the other Material Subſtance $\times c$ the Celerity, which Matter and which Celerity are Real, and not Abſtracted, as they exiſt in Nature?

The Celerities not ſo fully explain'd by this Philoſophy as they ſhould be.

§. 6. We have in the laſt Section conſider'd the Notion, which this Philoſophy aſſerts of Matter, and which will as well agree to Abſtracted Spaces, or Abſtracted Numbers, and inſtead of Matter, we may as juſtly take either the one or the other, in order to aſcertain the Moment of the Celerities; let us now examine the Celerities themſelves, and we ſhall find it difficult to prove, that they are Reciprocal to their Sums or Bulks to make their Moments Equal; for if the Celerity is the ſame, the Moments of Celerity will be as the Sums or Aggregates of it, if the Celerity is different, 100 of the ſame Celerities will hardly be Evidenc'd to be Equal to one Celerity, which is 100 Times greater; for altho' a Hundred of the ſame Celerities, deſcribe a 100 certain and determin'd Lines, yet one Celerity, which is 100 Times greater, do's not deſcribe a Hundred of the ſame Lines, but 10000 of Them; and the Moment or Force of ſuch Celerities cannot be the ſame, becauſe the actual Force of each will always keep the ſame Proportion of Difference to each other, in a longer or a ſhorter Line, namely, that of 1 to 100, ſo that the Force which Equably deſcribes 100 Lines, will never amount to that 100 Times greater Force, which deſcribes 10000: Since the Progreſs of the ſame Motion cannot give any Addition to it, ſo as to change it into a Greater; that is, from 100 into 10000, no more than 1 can riſe to 100; that is, if A is 100, and B is 1, and it is as $A.B::c.C$, the Celerity of c will be 100 Times greater than that of C, and where C deſcribes 1 Space, c will deſcribe 100; if therefore, AC deſcribes 100 Spaces, and Bc 100 with a Celerity 100 Times as great, the Celerity, in every Point of the laſt Line, will be 100 Times greater than in every Point of the Firſt, and the laſt Line, or Force of which it is the Effect, will be to the Firſt, as 10000 to 100, or 100 to 1; If c and C are only Sums of the ſame Celerities, the Proportion will hold of $A.B::c.C$, that is, as the Sum of the Parts of A, to the Sum of the Parts of B, ſo the Sum of the ſame Celerities c, to thoſe of C; or if A and B have contranitent Forces to c and C, as thoſe of Gravity are to thoſe of Velocity, and $A.B::c.C$, AC will be $= Bc$, but this will not be by conſidering A and B as mere Magnitudes, but as conſiſting of certain Gravitating Forces.

Matter and Celerity to be determin'd before we affirm any Thing of the Moments of Bodies.

§. 7. Notwithstanding which, it is affirm'd from this Propoſition, that the ſmalleſt Body may have a Moment Equal to the Greateſt, which is mov'd with any given Velocity; but by what foregoes, that will not be certain, till the Notion of Matter and Celerity is a little better determin'd.

From this Principle the Five Mechanical Powers are explain'd by this Philoſophy.

§. 8. It is farther from this Principle, that all the Mechanical Forces are explain'd, which are made uſe of, or contriv'd to Draw or to Raiſe Heavy Bodies, namely, if the Machines are ſo adjuſted, that the Celerity of the Power is to the Celerity of the Weight, as the Weight is to the Power, or ſince, if $c.C::A.B$, $AC = Bc$, ſuppoſing C is the Celerity of the Power, and c is the Celerity of the Weight, or Gravity to be mov'd, P the Power, and G the Weight or Gravity, if $C.c::G.P$, $C \times P = c \times G$, and in ſuch a Caſe the Power will ſuſtain the Weight; or, which is the ſame, the whole Moment of the one will be Equal to the whole Moment of the other, and this is endeavour'd to be exemplified by the Five Mechanical Powers.

Mr. Deſaguliers. Philoſph. Tranſact. Numb. 375.

Which we ſhall conſider, after we have made one ſhort Digreſſion to what has been lately Aſſerted in Proof of this Doctrine; Namely, that the Quantity of the Force of moving Bodies is to be Eſtimated, by multiplying the Maſs of the Bodies by their Velocity, and not by the Square of it, as it ſeems, *John Bernoulli*, *Wolfius*, *Hermannus*, and *Polenus* of *Padua* have affirm'd, in Defence of Monſieur *Leibnitz*, who firſt advanc'd this Opinion, which we are far from Maintaining, and do believe it to be more Abſurd than what is Avow'd and Patroniz'd by the Preſent Mechanicks; that is, the Principles of Nature, which we contend for, do reject both as Chimerical, and which have only their Riſe in the Mind and Fancy of the Philoſopher; The Firſt Opinion, which we ſhall only think it worth our Time to Examine into, and which if not True, it is Impoſſible the other ſhou'd be, becauſe our Arguments equally obtain againſt Determining the Moments of Bodies, by multiplying the Maſs of them into their Velocities, or the Square of their Velocities, or any other Power, Degree, or Proportion of Them whatſoever, ſince we ſay their own Intrinſick Forces are to be taken into the Computation, The Firſt Opinion is thus Defended;

If a Man, it is ſaid, with a certain Force, can Move a Weight of Fifty Pounds, thro' a Space of Four Feet in a determinate Time, it is certain he muſt employ twice that Force to Move one Hundred Pounds Weight, thro' the ſame Space in the ſame Time; But if he uſes but the ſame Force, he will Move the one Hundred Pounds Weight, but Two Feet in the ſame Time; and hence we are told it appears, that the Force is Proportionable to the Maſs multiply'd into the Velocity: And is it not Plain, that Matter is conſider'd, as Similar and Homogeneous, in this Demonſtration, and that there is nothing Imagin'd in it but Gravity or Weight? On the contrary, ſuppoſing we do not take Different Weights of the ſame Matter, but Different Portions of Different Matters, as for Inſtance, of Lead and Copper, or Wood, will it be affirm'd, that, if a Man with a certain Force, can Move Fifty Parts of Lead, thro' a Space of Four Feet, in a determinate Time, it is Evident, he muſt employ twice that Force to Move a Hundred Parts of Copper or Wood, thro' the ſame Space, in the ſame Time, and if he uſes the ſame Force, that he will Move the one Hundred Parts of Copper or Wood, but Two Feet in the ſame Time? If it is affirm'd, all the Experience in the World contradicts the Affirmation; If not, what becomes of this Argument to prove, that the Moments of all Bodies are Eſtimated, by multiplying their Velocities into their Parts or their Maſſes? If it is ſaid, that the ultimate Parts of Lead are the ſame, and have the ſame Weight, as the ultimate Parts of Copper, or Wood, that is what we have ever deny'd, and of which we ſtill require a Proof, which I am aſſur'd neither This, nor any other Philoſophy can give.

Of the ſame Nature is the Argument made uſe of from the Balance, which ſhews, that if the Brachium or Arm, on one Side the Fulcrum, is one Fourth of That on the other, a Weight of one Hundred Pounds, ſuſpended at the Extremity of the Former, will be Equal to Twenty Five Pounds, ſuſpended at the Extremity of the Latter, becauſe the Velocity of the Latter, if it were to Move, wou'd be four Times Greater than the Velocity of the Former, and therefore, ſince 1 Velocity, into 100 Weight, is = to 4 Velocity, into 25 Weight, the Moments of Bodies are to be Computed, from Multiplying their Maſſes into their Velocities, and not into the Squares of Them, for, if ſo, the Weight 25 ſhou'd be ſuſpended at half the Diſtance, ſince then the Square of 2 = 4, multiply'd into 25, wou'd be = to 100.

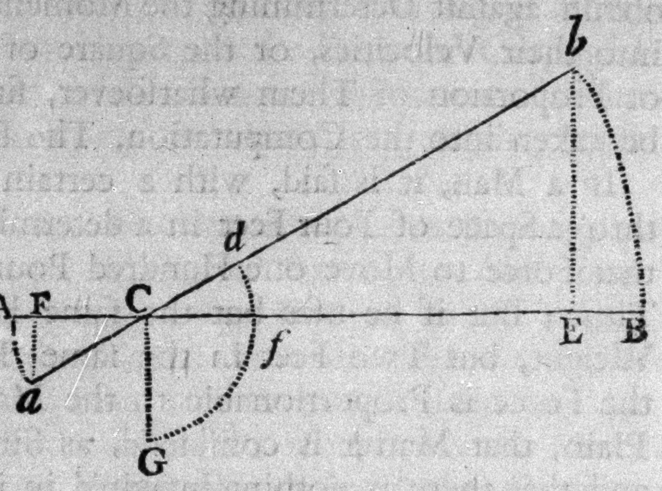
Let us allow this therefore to be a juſt Argument againſt *Leibnitz*, and his Followers, do's it yet Prove, what it wou'd Evince, that the Moments of Bodies are to be Eſtimated, by multiplying their Maſſes into their Velocities? Nothing leſs; it Proves it indeed, ſuppoſing Matter is Similar, and every Portion of it has the ſame Weight; but let us, as before, take Parts of Different Matter, and not the Weights of them, and the Fallacy will ſoon appear, For 100 Parts of Lead, ſuſpended at the Extremity of the ſhorter Arm of the Balance, will not be Equal, in their Moment, to 25 Parts of Copper or Wood, plac'd at the Extremity of the Longer.

Nor do the other Experiments of a Weight in a Scale at one End of the Beam, being rais'd by the Shock or Blow given by a Weight falling on the other, differ from what forego's, for if inſtead of Weights, we were to make uſe of Parts of

Different Matter, all this Reaſoning, as above, wou'd be of no Force to Prove, that the Moments of Bodies are to be Eſtimated from multiplying their Maſſes into their Velocities, but wou'd, with the Weight it alledges, fall to the Ground, ſince an Hundred, or a Thouſand Parts of Cork, or a Feather, will not by their Shock or their Blow raiſe 10 Parts of Lead, unleſs we again ſuppoſe, that the ultimate Parts of the one are the ſame, and have the ſame Gravity with thoſe of the other, which we humbly beg Leave once more to profeſs our Diſſent to, till we are ſo happy as to Meet with a farther Conviction of it; And now we ſhall Return to what we have many Years ago writ, and proceed to the Mechanical Powers.

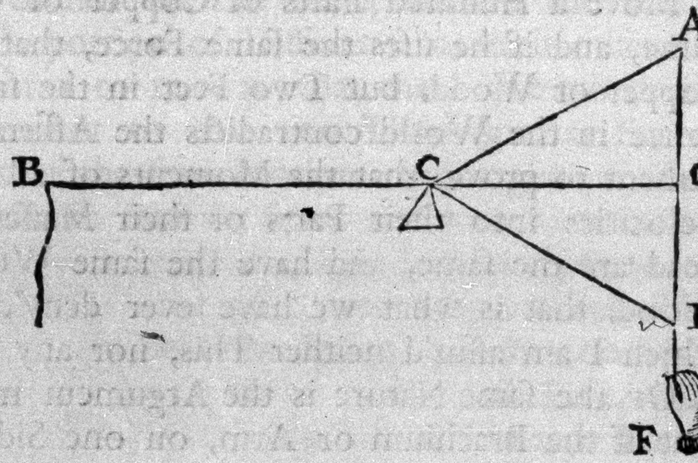
The Vectis or Firſt Mechanical Power, as explain'd by the Preſent Mechanicks. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 10. Dr. Wallis de Motu, Cap. 6. Prop. 1, &c. Part 3. Vol. 1. Sir Iſ. Newt. Princip. Leg. Corol. 2. & 6. & Schol.

§. 9. The Firſt is that of the Vectis, and in Order to give an Account of it, AB is ſuppos'd to be ſuch a one, whoſe Fulcrum is C, on which it moves; if ſo, it is ſaid, that the Space, which is deſcrib'd by each Point in it's Revolving, will be as it's Diſtance from C.



Caſ. 1. For let the Vectis be mov'd from it's Situation ACB, to that of aCb, the Point A will deſcribe the Periphery Aa, and B the Periphery Bb, but the Sectors ACa, BCb, being Similar, it will be, as $Aa . Bb :: AC . BC$, that is, the Spaces deſcrib'd by the Points, A and B, will be as their Diſtances from the Fulcrum C.

Caſ. 2. If to the Points, A and B, the Powers are affixt ſo, as to draw the Arms of the Vectis perpendicularly, the Spaces deſcrib'd will be as aF, bE, and ſince the Triangles aCF, bCE are Similar, it will be as $aF . bE :: aC = AC . bC = BC$.



Caſ. 3. If the Direction of the Power is not a Right Line, which is Perpendicular to the Vectis, but is inclin'd, as AF to CA, draw CG Perpendicular to the Line of Direction, and the Space deſcrib'd by the Power, as in Caſe the 2*d*, will be proportional to the Diſtance from the Fulcrum C, for it is the ſame Thing, whether the Thread AG, by which the Power acts, is affixt to A, G, or D; from whence it follows, that in all theſe Three Caſes, the Space deſcrib'd by any Power, according to it's proper Direction, is Proportional to the Diſtance of the Line of Direction from the Fulcrum.

All that is prov'd by this Demonſtration is only, that Different Radius's, drawn from the ſame Center, will deſcribe Similar Archs at the ſame Time.

§. 10. All therefore, which is Demonſtrated in this Theorem, is only this, that if the Line ACB, *Fig.* 1, is ſuppos'd to be mov'd on it's Center C, A will arrive at a, at the ſame time, that B comes to b, which is no more than to ſay, that in the Line CfB, where Cf is Equal to AC, f will come to d, at the ſame time, as B will to b, that is, in Concentrical Circles, Similar Archs of them will be perform'd in the ſame Time, and be in the ſame Proportion with the Radius's of them; for ſince the Motion of the Line ACB is only conſider'd, and what the Conſequence of ſuch a Motion will be, all that we can ſay in General is, that whether on this Side the Center C, or the other, Aa or df will have the ſame Proportion to Bb, as AC or Cf to CB, but what it will ſignify to explain the Mechanical Power of the Vectis, to ſay df is to Bb, as Cf to CB, we cannot readily apprehend; for CA is no more determin'd to deſcend, than Cf to riſe, that is, neither the one nor the other wou'd do it, excepting by ſuppoſing it, and the Line ACB will in Reality keep it's Situation, for all that has been yet Demonſtrated in this Theorem.

No Motion one way or other, or any Inclination to Motion prov'd.

§. 11. We conſequently acknowledge, that if the Line ACB is mov'd round it's Center C, it will deſcribe Aa, df, and Bb, at the ſame Time, for the like Reaſon, that in deſcribing a Circle, all the Concentrical Peripheries will be perform'd by the ſame Motion of the Radius; But which way are we from thence made to underſtand any more, how *Cb* ſhou'd actually, and not in Suppoſition only deſcend, for inſtance to *CB*, at the ſame Time, that *Ca* riſes to *CA*, than how *Cdb* ſhou'd deſcend to *CfB* in fact, by ſuppoſing an imaginary Motion only, which preſumes, in the Deſcription of Concentrical Circles, that *CfB* may aſcend, or *Cdb* deſcend, and therefore, that there is no real Inclination to move one way more than another?

§. 12. Besides, if *ACB* is an Abſtracted and Mathematick Line, which has no Weight, nor no Dimenſions, except that of Length, *CB* will weigh no more than *AC*, and therefore, notwithſtanding this Geometrick Reaſoning, *ACB* will continue in the ſame Poſture, without any Propenſity to Move one way or other, if it is Mov'd by Suppoſition, there can be nothing more collected from thence than that Concentrical Circles are deſcrib'd in the ſame Time, and that the Celerities of their Deſcription, or their Spaces, are Proportional to their Diſtances from their Center; but this is no Explanation how the Power and the Weight perform ſuch Spaces, ſince, altho' *Aa*.*Bb*::*AC*.*BC* in this Figure, where *B* and *A* are indiviſible Points, and *AC* and *BC* Geometrick Lines, yet, other Things being the ſame, as in the preſent Scheme, if two Bodies of Equal Matter and Bulk are affixt to *B*, and *A*, theſe Spaces will not be deſcrib'd by them, becauſe *B* and *A* being Equal, and the Scheme continuing the ſame, there will no real Motion enſue; and whatever Motion is introduc'd, muſt be, as before, by Suppoſition, unleſs *B* and *A*, when conſider'd as Equal Points, are different from *B* and *A*, when conſider'd as Equal Congeries of the ſame kind of Points, which is impoſſible, for all Equal Parts, equally multiply'd, will have the ſame Relation to each other, as their Simples.

If two Equal Magnitudes are affixt to the Extremities of the Vectis, conſider'd only as a Geometrick Line, nothing will from thence enſue.

§. 13. If the Parcels of Matter affixt to the Extremities of the Vectis are Unequal, ſo are likewiſe the Lines *AC*, *CB*, which yet will continue in the Poſition *ACB*, unleſs they are ſuppos'd to be mov'd; if therefore *B* and *A* (which, tho' Portions of Matter, are nothing more than Portions of Abſtracted Space in this Philoſophy, by §. 5.) are unequal Portions of Space (as *AC* and *CB* are), there can be no Reaſon aſſign'd, why ſuch unequal Portions of Space ſhou'd any more cauſe a Motion in the Vectis, than why *AC* and *CB* ſhou'd, which are unequal Portions of Abſtracted Space, and therefore *ACB* notwithſtanding theſe Appendages of Abſtracted Matter, at the Extremities of the Vectis, will not be put into Motion, without a Suppoſition of it.

If two Unequal Magnitudes are affixt to this Geometrick Line, nothing will be conſequent from thence.

§. 14. Farther, if *B* is of the ſame Sort of Matter with *A*, and it's Bulk is Reciprocal to it's Diſtance from *C*, with that of *A* from *C*, for the ſame Reaſon, as in the former Section, *ACB*, with theſe Reciprocal Appendages of their Diſtance from *C*, will yet ſtill be unable to move out of the Situation *ACB*, to that of *aCb*, without a Suppoſition of Motion to aſſiſt it's Inactivity, for if Unactive and an Abſtracted Matter is affixt to an Abſtracted and Unactive Line, it is impoſſible any Action ſhou'd reſult from it.

If the Magnitudes are Reciprocal to the Diſtances from the Center, all will continue without any Motion or Inclination to it.

§. 15. If, moreover, *B* is not of the ſame kind of Matter with *A*, and they have different Forces, it is a Contradiction to the fundamental Hypotheſis of this Philoſophy, which ſuppoſes all Matter to be the ſame; and if ſuch an Hypotheſis is not true, as we have endeavour'd to prove it is not, The Motion of *A* and *B*, as it is propos'd in this Philoſophy, will be much leſs aſſerted by the preſent Theorem than before, as will be evident, if Lead is plac'd at one End of the Vectis, and Fire or Light, or even an Equal Portion of Wood or Cork, at the other; But this Argument we have urg'd more at Large, §. 8.

If Matter has Forces, and they are different in themſelves, this Theorem will not be true.

§. 16. Supposing yet all Matter to be the ſame, and ſome kind of Action, as Gravity, is introduc'd into it, which we will likewiſe preſume Proportionable to the Matter which Gravitates, the contrary to which we have notwithſtanding prov'd, both in this Part of our *Principles of Philoſophy*, and more particularly in the Firſt; let now the Gravitation of *A* be Equal to that of *B*, if ſo, for ought, that has been hitherto Demonſtrated, it do's not appear, that *ACB* will change it's Situation by this Acceſſion of a perpendicular Action or Gravity, for, if the Abſtracted Diſtance of *CB* and *CA* can ſignify nothing to make *B* or *A* incline one way or the other, as has been before ſhewn, the Addition of Equal Weights cannot be of any great Importance to the Depreſſing the one Part of the Vectis, or Raiſing the other.

If Matter is the ſame, and has a Force of Gravitation Proportional to the Matter which Gravitates, this Theorem not prov'd.

If the Portions of Similar and Gravitating Matter are Reciprocal to their Diſtance from the Center, they are not prov'd by this Theorem to be in an Equal Poiſe.

§. 17. For the Reaſon, which is alledg'd in the foregoing Section, if the Weight of *A* is Greater than that of *B*, or the contrary, and they are in a Reciprocal Proportion to their Diſtances from the Fulcrum, it will not be neceſſary, that the Moment of *A* ſhou'd be Equal to that of *B*, becauſe, if, where *A* and *B* are Equal Weights, or have an Equal Force of Gravitation, the Line or Vectis *ACB* is unmov'd, it will follow, that where *A* and *B* are unequal Weights, and in a Reciprocal Proportion to their Diſtances from the Fulcrum, they will not be Equally pois'd, ſince the Diſtances *CA* and *CB* have no Influence or Moment (as they are Abſtracted Lines) in the aſſiſting the Gravitation of the one Body or the other.

If the Line ACB *is not a Geometrick but a Gravitating Line, nothing can be concluded from this Abſtracted Reaſoning.*

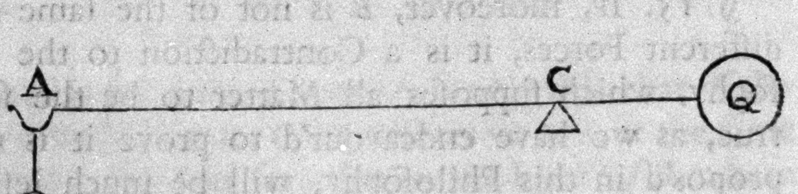
§. 18. Lastly, if we do not conſider the Diſtances, *AC* and *BC*, from the Fulcrum, as Abſtracted Lines, but as one Gravitating continued Line, the Caſe will be ſtill more perplext in Reſpects of the Weights, *A* and *B*, which have been hitherto imagin'd to exert their Gravitation or Action at the Extremities of the Abſtracted Line *ACB*, ſince, if now the Abſtracted Line *ACB* is ſuppos'd to conſiſt of Real Matter, which Gravitates, all the Parts of it will be as ſo many Gravitating Bodies, *A* and *B*, in their ſeveral Diſtances from the Fulcrum, and therefore, in this Abſtracted Reaſoning, will be of no greater Significance to the Weighing down the one Part of the Vectis than the other.

What ought to have been Demonſtrated in the foregoing Theorem.

§. 19. In fine, what is wanting in the whole Demonſtration is to ſhew, that ſuppoſing *C*, *f*, *E*, and *B*, to be four Gravitating Points, acting Downwards in a Perpendicular, with an Equal Force of Gravitation, and yet detain'd by the Point *C* from Receding from thence, what the Spaces will be which they deſcribe, which at *C* can be none, at *f*, *E*, and *B*, will be ſo many Quadrants, made by the Radius's *Cf*, *CE*, and *CB*, which will each of them Coincide with *CG* at the ſame Time, upon this Suppoſition, that at *f*, *E*, and *B*, the Celerities will be Greater, the farther thoſe Points are from the Center of their Detention *C*, tho' their Perpendicular Gravities are ſuppos'd to be the ſame, which is nothing more than a Reaſonable Preſumption, if it is not an Axiom; becauſe, if, at *C*, the Gravitation is entirely hindred from Exerting it's Action into the Deſcribing any Space, and only preſſes in a Point, the Action of a Similar Gravity, which is here ſuppos'd, will ſuitably obtain it's own Force in Proportion more fully, and ſtrongly, the farther it is remov'd from that Point, where it's Effect in Celerity was Equal to nothing, that is, was wholly Obſtructed; and by Conſequence ſuch an Equal Action, as that of Gravitation, will be more forcible, and be carried with a greater Celerity in a greater Diſtance, from the Center of it's Detention, than in a Leſſer; and if ſo, one Gravitating Point at *B*, may be Equal in it's Force to Ten at *A*, or *f*; but of This we ſhall ſay more at the End of this Philoſophy of the Mechanical Powers.

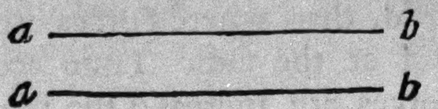
Theorem the Eleventh explain'd; That, in a Vectis, which is in an Æquilibrium, The Power is to the Weight, as the Diſtance of the Weight from the Fulcrum, to the Diſtance of the Power from it. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 10. Dr. Wallis de Motu, Cap. 6. Prop. 1, &c. Part 3. Vol. 1. Sir Iſ. Newt. Leg. Corol. 2. & 6. & Schol.

§. 20. The next Theorem, which is founded upon the foregoing Principles, is, that in a Vectis, the Vis Motrix, or Power, as *P*, which has the ſame Proportion to the Weight *Q*, which the Diſtance of the Line of Direction of the Weight from the Fulcrum, namely, *CQ*, has to the Diſtance of the Direction of the Power from the Fulcrum, to wit, *CA*, will ſuſtain the Weight; that is, if $P . Q :: CQ . CA$, $Q \times CQ$ will be $= P \times CA$, or the Power of *P*, in ſuch a Circumſtance of it's Diſtance from *C*, will be Equal to the Weight *Q*, conſider'd at the Diſtance of *CQ*; becauſe the Ratio of the Moments of any Body is compounded of the Ratio's of the Quantities of Matter, and of the Celerities, that is for Example, 3 Portions of Diſtance into 4 of Matter are Equal to 3 of Matter into 4 of Diſtance, and in the preſent Caſe, ſince the Celerities are Proportional to the Diſtances, 3 Portions of Celerity into 4 of Matter are Equal to 3 of Matter into 4 of Celerity, that is, 1 Portion of Celerity, and, by Conſequence, of Diſtance in the Vectis, is always to be computed to have the ſame Force as 1 Portion of Matter, and ſo on the Contrary, or, let *C* be the Celerity of the Power, *c* of the Weight, *P* the Power, *G* the Gravity or Weight, it will be, $P . G :: c . C$, and $PC = Gc$.



Three Anſwers to the forego-ing Abſtracted Reaſoning.

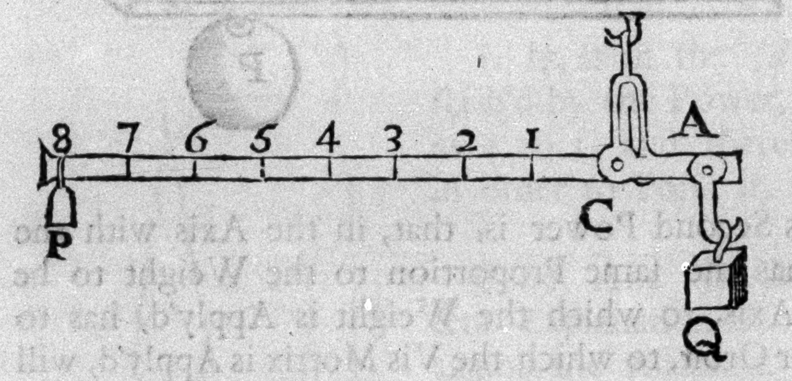
§. 21. In Anſwer to which we may ſay, that Firſt, according to what we have already ſhewn, it is not neceſſary to ſuppoſe Matter alike, and to be no other than a Congeries of ſo many Points of Abſtracted Space or Number, which ſerve only to Count up the particular Ingredient Celerities, that make up the whole Moment or Quantity of Motion: Second, That if Matter was this Similar Being, which ſhou'd only conſiſt of ſo many Points, by which we ſhou'd reckon the Sum of the whole Motion, yet it is not Evident that a Sum of the ſame kind of Celerities, is Equal to any Sum of Celerities, which are of a different Nature and Activity, as ſuppoſing, *Q* is 4, and *P* is 3, and the Celerity of *Q* is 3, and that of *P* is 4, it is no more prov'd, that theſe Moments are Equal, than that a double Celerity has the ſame Force, that two Equable ones have; thus let Two Points, *a*, *a*, move in the ſame Time to *b*, *b*, the Force or Activity of ſuch a Celerity will be expreſs'd by either of theſe Lines, which will never riſe to the Force of a double Celerity, which deſcribes *a b* in half the Time, or twice *a b* in the ſame Time, ſince *a*, *a*, moving together in the ſame Time, is, as if *a* ſhou'd move twice the Length of *a b* in double the Time, but *a* moving, where the Celerity is double, thro' *a b* in half the Time, or thro' twice *a b* in the ſame Time, cannot be Equal to *a* moving thro' *a b* in the ſame Time, or twice *a b* in double the Time: Third, If Matter was the Abſtracted Being, which it is repreſented to us, and Unequal Celerities had Equal Forces, or Moments with the Sums of the ſame Celerities, yet, by what has been ſaid concerning the Vectis, it wou'd not be Equally pois'd by ſuch a Reciprocal Matter and Celerity, any more than it wou'd by an Equal Matter affixt at both the Extremities of it, which we have Evidenc'd, §. 16 and 17, will be as entirely in an Æquilibrium, as any Reciprocal Matters or Portions of it, which we can name, and therefore deſtroys this Reaſoning, which ſuppoſes the Reciprocal Diſtances neceſſary to the Equal Balance; For it is ſhewn in thoſe Sections, and in others Preceding, that there will be no Motion of *A C Q* in any Caſe, unleſs upon a Suppoſition of it; that is, to make theſe Celerities Reciprocal, the Vectis is put into Motion by the Mind, which Motion is not prov'd or deduc'd from any Principles alledg'd in this Philoſophy.



The Roman Balance made uſe of to confirm this Theorem.

Dr. Keill's Intr. ad ver. Phyſ. Lect. 10.
Dr. Wallis de Motu, Cap. 3. Prop. 25. Part 1. Vol. 1.
The Counterpoiſe like a Pomgranate, Hebr. *Rimmon*, Arab. *Romman*, and us'd in *Turky*, as here.

§. 22. 'Tis true the Roman, or according to Dr. *Wallis* the *Romman*, Balance is made uſe of, as an Inſtance, to juſtify this Reaſoning, where *C* is the Fulcrum, *C A* the Diſtance of the Pondus to be examin'd, *P C* is the other Part of the Beam, which is diſtinguiſh'd into 8 ſeveral Portions or more, as there ſhall be occaſion, *P* is a Weight (ſuppoſing a Pound) already known, if therefore at *P*, where the Beam is 8 Times longer than *C A*, *P* is in an Equal Balance with *Q*, *Q* is 8 Pounds, as *P* is 1, that is, the Weights are in a Reciprocal Proportion of their Diſtances from the Fulcrum *C*.



Not Accounted for by this Theorem.

§. 23. On the contrary, this Example of the Roman Balance is ſo far from confirming the former Reaſoning, that the former Reaſoning ſeems to be contriv'd to Account for this Balance, the Principles of which, ſince they are not Capable of Explaining the Propoſitions, which are deſign'd to be Preparatory to it's Solution, cannot be any ways ſignificant to an Expoſition of it.

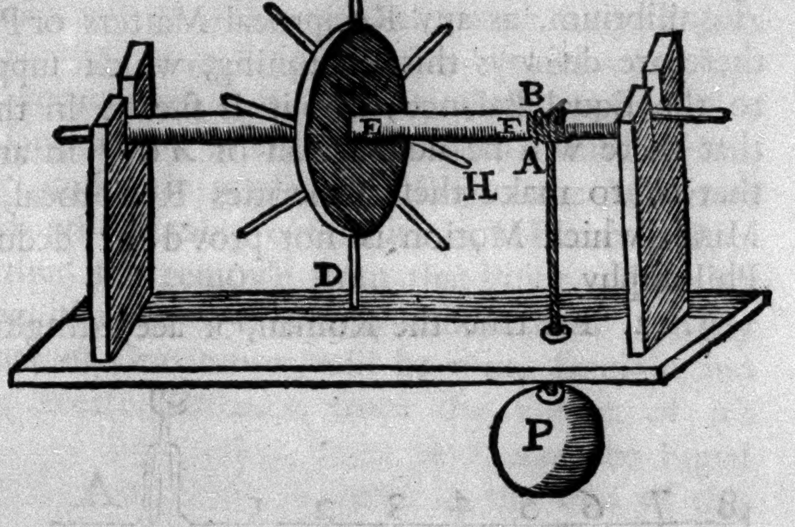
Not Accounted for by this Theorem.

§. 24. Besides which, if all, that has been hitherto confuted, was true in Reſpect of the Balance not moving at all, unleſs by Suppoſition, it wou'd not prove, that *P* and *Q*, in the preſent Circumſtance of their Diſtances from the Fulcrum being Reciprocal to their Weights, wou'd be in an Equal Poiſe with each other: Firſt, Becauſe the Weights of the Bodies *P*, *Q*, are here ſubſtituted inſtead of the Celerities, whereas it is not manifeſt, from this Philoſophy, that Forces, which Equally deſcend, and are only diſtinguiſh'd by the different Sums or Aggregates of them, are Anſwerable or Analogous to different Forces of Celerity, according to Argument the ſecond, §. 21; Second, Becauſe, if that was allow'd, the Point *Q*, and that at *P*, wou'd be in an Equal Poiſe without any Appendage of Reciprocal Portions of Matter to their Diſtance from the Fulcrum; ſince if *Q* moves with 1 Celerity, and *P* moves with 8, and ſince at the ſame Time, that *Q* moves with it's Celerity about the Fulcrum *C*, *P* will obtain it's own Celerity likewiſe, it will be impoſſible for *Q* or *P* to Preponderate, from whence it follows, that the Point *Q* and the Point *P*, without the Addition of the Weight *Q* on the one Hand, or *P* on the other will be in an Æquilibrium; if therefore, the Weight *Q* is added to one Extremity, and *P* at the other, the firſt of which is ſuppos'd 8 Times Greater, in it's Force or Gravitation, than the laſt, the Preponderancy will be on the Side of *Q*, according to this Reaſoning, which, by Experiment, do's not Preponderate at all.

FROM all which it is manifeſt, that, inſtead of proceeding in this Abſtracted Way, the Preſent Philoſophy, according to §. 19, ſhou'd have prov'd, that, where Forces are ſuppos'd to Gravitate Equally, and in a Perpendicular, and at the ſame Time are detain'd ſo, as not to recede from the Fulcrum *C*, thoſe Forces are increas'd the farther they are remov'd from that Fulcrum, or the Centre of their Detention, and in Proportion to their Removal from it; which will ſolve the Properties of the Vectis, and the Roman Balance, and will anſwer the Difficulties, which I have rais'd againſt the Preſent Reaſoning, becauſe, in ſuch a Caſe, *AP* is not conſider'd as an Abſtracted Line, and the Celerities are not conſider'd as Abſtracted ones, but Different in themſelves, and ſuch as may Balance a contrary Force of Gravitation oppos'd to them, for by that Means *P* will have a Force of Percuſſion or Celerity Impreſs'd upon it, which will be Equal to the Gravitating Force in *Q*.

The Axis in Peritrochio deſcrib'd, which is the ſecond Mechanical Power.

§. 25. THE next Mechanical Power after the Vectis, which we are to enquire into, is the Axis in Peritrochio, the Axis is the Cylinder ſupported by two Fulcrums at the Extremities of it, and the Peritrochium is the Circular Body affixt to the Axis, to which ſeveral Scytalæ, or Handles, are ſuppos'd to be join'd, and by a Force apply'd to one of theſe Scytalæ, the Pondus *P* is to be rais'd. This is the Deſcription of the preſent Mechanical Power, and the Theorem, which is form'd upon it, we ſhall explain in the following Section.



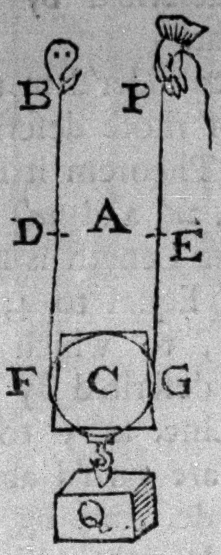
The Theorem form'd upon this Mechanical Power; That the Power is to the Weight, as the Perimeter of the Axis to the Ambitus of the Scytala. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 10. Theorem 12. Dr. Wallis de Motu, Cap. 7. Part 3. Vol. 1. Sir Iſ. Newt. Princip. Leg. Corol. 2. & 6. & Schol.

§. 26. THE Theorem to Explain this Second Power is, that, in the Axis with the Peritrochium, the Vis Motrix, which has the ſame Proportion to the Weight to be ſuſtain'd, which the Perimeter of the Axis, to which the Weight is Apply'd, has to the Perimeter of the outmoſt Ambitus or Orbit, to which the Vis Motrix is Apply'd, will be Equal to the Weight; if therefore ſuch a Vis Motrix is never ſo little augmented, it will be ſufficient to raiſe the Weight, to which it was before Equal; For the Weight *P* is drawn up in Proportion, as the Line, from which it depends, wraps about the Axis, and therefore in one Revolution of the Axis, the Weight will be anſwerably rais'd the Length of the Axis's Ambitus, and at the ſame Time the Power, or Vis Motrix, apply'd to the Scytala, or Handle of the Peritrochium, will deſcribe the Circumference made by the entire Revolution of it, that is, the outmoſt Orbit, or Ambitus perform'd by the Vis Motrix; from whence it follows, that the Celerities of the Power, and the Weight, which are as the Spaces they deſcribe, will be as the Perimeter of the outmoſt Orbit to the Perimeter of the Axis, wherefore, if the Weight is to the Power, as the Perimeter of the outmoſt Orbit to the Perimeter of the Axis, the Celerity of the Power will be to that of the Weight Reciprocally, as the Weight to the Power, which, by what foregoes, is the Condition requiſite to make the Power and the Weight in an Equal Balance; that is, let *C* be the Celerity of the Power, *c* of the Weight, *P* the Power, and *G* the Gravity or Weight, it will be as $P . G :: c . C$, and $PC = Gc$.

The Axis with the Peritrochium exactly

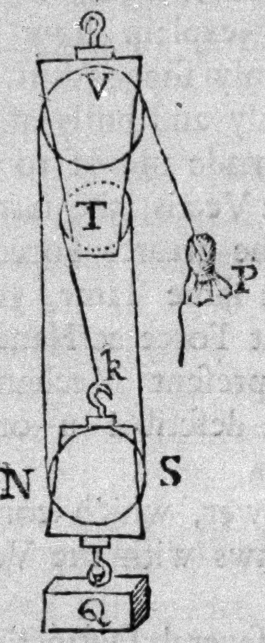
§. 27. IF we conſider the Circumferences of the Axis *AB*, and of the Scytalæ *CD* to be drawn from the ſame Center *E* or *F*, and whilſt *C* moves from thence to *H* and *D*, we imagine *A* to deſcribe an Oppoſite Arch, from thence to *B*, the Caſe will be exactly the ſame, as that of *Fig.* 1. §. 9. where *CB* will repreſent *EC* in the Figure before us, and *AC* that of *AF*, ſo that there is nothing more to be prov'd in this Mechanical Power than that any equally Gravitating Point has a greater Force in Proportion to it's Removal from the Center of it's Detention.

the ſame with the Vectis and the Roman Ballance, and therefore admits of the ſame Anſwer.

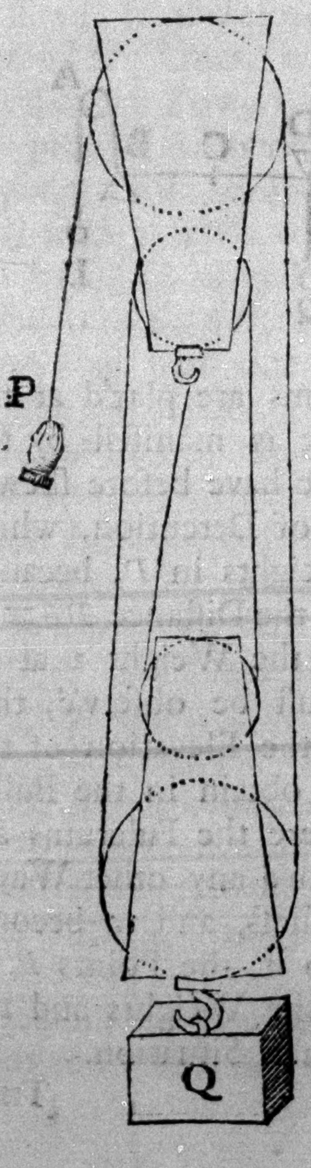


§. 28. The Third Mechanical Power is that of the Trochlea, Polyſpaſt, or Pully, which is accounted for by the following Theorem, That the Force, which is to the Weight, as 1 to the Number of Lines by which the Weight is ſuſpended, will be ſufficient to bear up that Weight, and if increas'd, will ſurmount it; Let there be a Line, one of whoſe Extremities is affixt to the Uncus *B*, in the Fold or Doubling of which let the Pully be plac'd with the Weight annext to it, and the other Extremity to *P*; in order to raiſe the Weight *Q* one Foot from *C* to *A*, there will be two Foot of the Lines *BF*, *PG* carry'd upwards at the ſame Time, namely, from *F* to *D*, and from *G* to *E*, ſuppoſing the Diameter of the Pully *FCG* to be inconſiderable; or, which is the ſame, the Uncus remaining fixt, whilſt *P* is mov'd upwards, to cauſe *C* to aſcend to *D*, *D* and *C* will be Coincident, ſo that *DCE* or *DFGE* will have mov'd twice as far as *CA*, that is, by that Time *C* arrives at *A*, *D* will come to *E*, and *E* will riſe as far above *P*, as *G* is below *E*, in both which Caſes, the Line of the Force or Power will deſcribe Double the Space of what the Weight do's; from whence it follows, that the Celerity of the Power will be Double the Celerity of the Weight, and conſequently, if the Power is to the Weight, as 1 to 2, it's Moment will be Equal to that of the Weight, and therefore will ſuſtain it.

The Third Mechanical Power explain'd, which is That of the Trochlea or Pully, and the Theorem, that the Power or Force is to the Weight, as 1 to the Number of Lines, by which the Weight is ſuſpended. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 10. Dr. Wallis de Motu, Cap. 8. Part 3. Vol. 1. Sir Iſ. Newt. Princ. Leg. Corol. 2. & 6. & Schol.



2. If, as in the 2*d* Figure, Three Lines are us'd to raiſe the Weight one Foot, the Space, which the Power deſcribes, will be to that, which the Weight do's, as 3 to 1, and therefore the Power ought to be to the Weight, as 1 to 3.



3. If, as in the 3*d* Figure, Four Lines are us'd, the Space deſcrib'd by the Power, to that deſcrib'd by the Weight, will be as 4 to 1, and therefore the Power muſt be to the Weight in order to Poiſe it, as 1 to 4, and ſo on in Infinitum.

§. 29. All the Difficulties before alledg'd againſt the Preſent Explanation of the Mechanical Powers, are alike Valid againſt the Account, which is given of this, namely, that the Matter to be rais'd is conſider'd as Similar and Homogeneous, that Gravity is likewiſe the ſame in all Bodies, *&c.* What we have to ſay here, in particular, is, that the Center of Detention is *B*, *Fig.* 1. of the foregoing Section, and if *P* is ſuppos'd to be a fixt Point, it will be another Center of Detention likewiſe, which will together ſuſtain the Body *Q*, whether the Lines are Longer or Shorter, or whether *Q* has a Greater or Leſs Weight; and let the Line or Space, which *P* is ſuppos'd to deſcribe to Balance the Weight, be what it will, it ſignifies nothing to the Support of it, if *P* is not ſuppos'd to be a Center of Detention, and if the Power lies in the Space to be deſcrib'd, without an Actual Force in *P*, Equal to that in *B*, to ſupport the deſcending Body, ſince it will certainly deſcend, notwithſtanding any Imaginary Lines or Spaces, which are deſcrib'd in the Fancy to ſuſtain it; For a double Line, which is to be deſcrib'd by the Power in *P*, can never ſupport a double Weight in *Q*, it muſt be an actual Force in *P*, which, together with the Uncus *B*, will be Equivalent to the Weight in

The Objections which lye againſt the Explanation of this Third Mechanical Power.

in *Q*, and not a Space to be deſcrib'd by *P*, which will be capable of obtaining that Effect; the Trochlea therefore in this Scheme is nothing elſe but a Vectis, which has a Fulcrum at each Extremity, with this Difference, that the Trochlea has it's Diſtances from the Fulcrums Perpendicular to the Horizon, whereas thoſe of the Vectis are Parallel to it. Moreover $DFGE$ are not Lines Double of AC, and, whilſt *C* moves to *A*, there will be more than Double that Space deſcrib'd by the Line round the Pully, in order to Elevate the Weight to that Height.

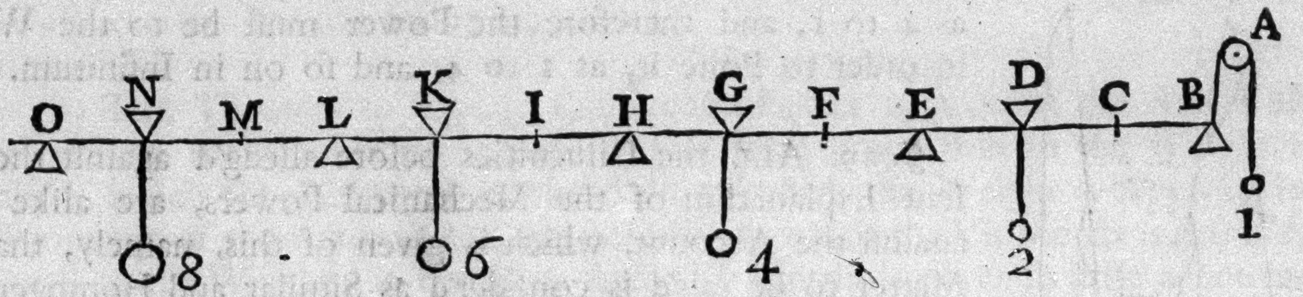
Other Objections againſt this Explanation.

§. 30. We muſt farther obſerve, that the Length of the Lines is conſider'd in this Explanation, to make the Spaces deſcrib'd by the Power, Double of thoſe deſcrib'd by the Weight, that is, AC is half of $DF+GE$, *Fig.* 1, and yet in the Theorem it ſelf, the Number of Lines is only conſider'd; on the other Hand, in *Fig. 2d*, and 3*d*. the Length of the Lines is not conſider'd, nor the Number of them; the Length is not, unleſs VN is Equal to $ST=TR$, nor the Number, if 3 is not Equal to 4, or $NV+ST+TR=$ to $NV+ST+TR+VP$, for, in the 2*d* Figure, to which we Refer, the Power is to the Weight, as 1 to 3, becauſe the Spaces, deſcrib'd by the 3 Lines of the Power, are to the Elevation of the Weight in one Line, as 3 to 1, when the Lines are neither Equal, nor have an Equal Direction, nor are turn'd about Equal Pullies, all which are at leaſt neceſſary to make the Spaces deſcrib'd by the Power 3 Times as much, and no more, than that deſcrib'd by the Weight; If this yet were true, ſince VP is alſo added, it will be Impoſſible to explain how the Action of 4 Lines, ſhou'd have the ſame Effect as 3, which are only ſuppos'd in deſcribing 3 Times the Space, which 1 Line do's, unleſs we can truly and juſtly affirm that 3 is Equal to 4; and it is manifeſt there are only 2 Lines made uſe of to deſcribe a double Space in *Fig.* 1. But we ſtill Inſiſt, that tho' in the Vectis, the farther any Gravitating Point is Diſtant from the Center of Detention, the greater Force of Velocity it has, and therefore will deſcribe a greater Space in the ſame Time, yet a greater Velocity to be deſcrib'd, is no Argument, that there is that Force at Hand to deſcribe it, till ſuch Force is prov'd, which is not done in the preſent Mechanical Power, but aſſum'd, becauſe a greater Velocity is Requiſite to be deſcrib'd in order to Elevate the Weight.

A True Account of this Mechanical Power, by which it is reduc'd as the Former, to that of the Vectis.

§. 31. The Trochlea or Pully therefore is that Mechanical Power, which conſiſts of ſeveral Centers of Detention, and which obſerves the ſame Laws with the Vectis with Two Fulcrums at the Extremities of it.

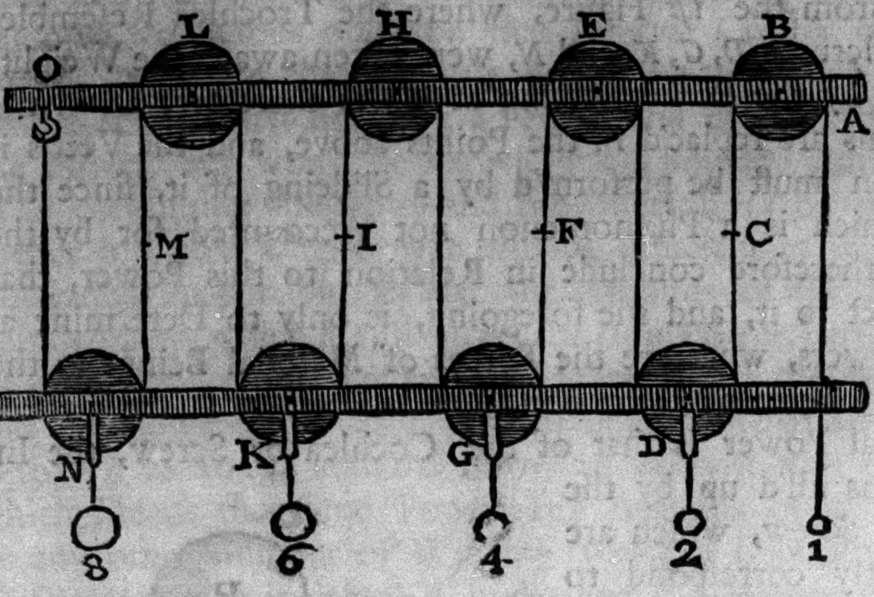
Thus let BO repreſent a compound Vectis, divided into it's ſeveral Diſtinctions, *B, C, D, E, F, G, H, I, K*, &c.



In the firſt Part of it, BE expreſſes a Vectis, whoſe Fulcrums are plac'd at the Extremities of it in *E*, and *B*, with an Oppoſite one at *D*. It is manifeſt by the Laws of the Vectis, and it's Forces, which, according to what we have before ſhewn, are increas'd in Proportion to their Diſtance from the Center of Detention, which here is the Fulcrum *E*, that 1 Weight in *B*, is Equal to 2 Weights in *D*, becauſe, as the Diſtance $ED=1$, from the Center of Detention *E*, is to the Diſtance $DB=2$, from the Center of Detention *D*, ſo the Weight 1 at *B*, is to the Weight 2 at *D*, that is, $ED\,.\,DB::W1\,.\,W2$, and $W1\times DB=W2\times ED$. It muſt be obſerv'd, that we, at preſent, ſuppoſe the oppoſite Fulcrum *D*, not to hinder the Elevation of the Weight 2, and ſo of the other oppoſite Fulcrums, which only obtain in the Pully, and are the Occaſion of the Slideing Motion in it, ſince, where the Fulcrums are oppoſite to each other, it is Impoſſible Motion ſhou'd be perform'd any other Way.

Let now the Vectis be ſuppos'd to looſe it's Rigor and Stiffneſs, and to become Pliant and Yielding to the Weights, and the Fulcrums annext to it, the Points *E, D, C, B, A* will retain the ſame Forces, as before, in Reſpect of the Weights and the Fulcrums, and will only change their Horizontal to a Perpendicular Situation.

Thus



THUS $ED2CBA1$, in *Fig.* 1. will fall into $ED2CBA1$, *Fig.* 2. in which the Lengths of the Perpendicular Lines are of no Conſideration, and only the Relation, which they have to their Fulcrums, is Regarded; $BA1$ is nothing, $BCD=2$, and $DE=1$.

THE ſecond Portion of the Vectis *Fig.* 1. is EH, Let $ED2$ be turn'd round a Pully in E, by the Former Vectis, or Pully, $2W$ in D, $=1W$ in B, therefore the whole Weight or Power, in the Former Vectis or Pully, will be $=$ to $2W$ in E; and for the ſame Reaſon, as before, the Weight 2 in E, will be Equal to the Weight 4 in G, becauſe $HG=1$, the Diſtance from the Center of Detention H, is to $GE=2$, the Diſtance from the Center of Detention G, as the Weight 2 to the Weight 4, that is, $HG.GE::W2.W4$, and $HG\times W4=GE\times W2$, but $W2$ in D, or E, $=W1$ in B, or A, and therefore $W1$ in B, or A, $=W4$ in G.

THE third Diviſion of this Compound Vectis is HL, in which let $HG4$ be thrown round a Pully in H, and the Weight 4 in H will be Equal to the Weight 6 in K, for the whole Moment or Weight of the Two former Vectes or Pullies were $1W$ in B, or A, $=2W$ in D, $=4W$ in G, and all of them $=3W$ in H, but $LK=1.KH=2::3W$ in $H.6W$ in K; or $1W$ in A, or B, $=6W$ in K.

THE laſt Part of this Compound Vectis is LO, in which $1W$ in A, or B, $=2W$ in D, $=4W$ in G, $=6W$ in K, and all of them $=4W$ in L, but $ON=1.NL=2::W4$ in $L.W8$ in N, and 1 Diſtance $\times\ 8W=2$ Diſtance $\times\ 4W$.

LET the whole Vectis, which may be continu'd in Infinitum, become Limber and Pliant to the Weights, which depend from it, and the Three laſt Diſtinctions of it, as well as the Firſt, will Sink into Pullies, and $EFG4H$, in the 1*ſt* Figure, will fall into $EFG4H$, in the 2*d*, $HIK6L$ into $HIK6L$, and $LMN8O$ into $LMN8O$.

A Confirmation of the Former Account of the Pully.

§. 32. IF therefore we now make uſe of the Number of Pullies themſelves, and not of the Lines, which encompaſs them, for a Solution of the Properties of this Mechanical Power, we ſhall eſcape all the Difficulties, which we have urg'd againſt the preſent Account, and ſhall find here the Forces, which are wanting there, to explain thoſe Properties; Thus with 2 Pullies B and D, and a Fulcrum E, $1W$ will ſuſtain $2W$; with 4 Pullies B, D, E, G, and a Fulcrum H, $4W$; with 6 Pullies B, D, E, G, H, K, and a Fulcrum L, $6W$; with 8 Pullies B, D, E, G, H, K, L, N, and a Fulcrum O, $8W$, &c. From hence alſo it is manifeſt, that in Pullies, which are not connected with one another, but are ſuſtain'd by ſeveral Diſtinct Fulcrums, the Force of the 2*d* will be Double of that of the 1*ſt*, that of the 3*d* Double of that of the 2*d*, and that of the 4*th* Double of that of the 3*d*, &c. as alſo, that $1W$ will ſuſtain $5W$ with five Pullies connected with one another without any Diſtinct Fulcrums; From hence it is farther Evident and Plain, that every Center of Detention weakens the Force of Gravitation, as in the other Mechanical Powers, every Removal from it, Increaſes it, that is in General, according to the Notion before Explain'd of Expanſive and Contractive Forces, the Center of Detention has in this Caſe a Contractive Force, and hinders Expanſion and Velocity, and the Gravitating Force in Reſpect of ſuch a Center is an Expanſive one, tho' in other Reſpects and Relations, as in Fire or Flame, 'tis a Contractive. So in the Trochlea or Pully, nothing can be more certain than, if we hang two Equal Weights upon it, they will be detain'd by it from Deſcending, and there will be one Center of Detention, if we make uſe of 2 Pullies, there will be 2 Centers of Detention, if of 3, there will be 3 Centers of Detention, *&c.* according to the Figures preceding.

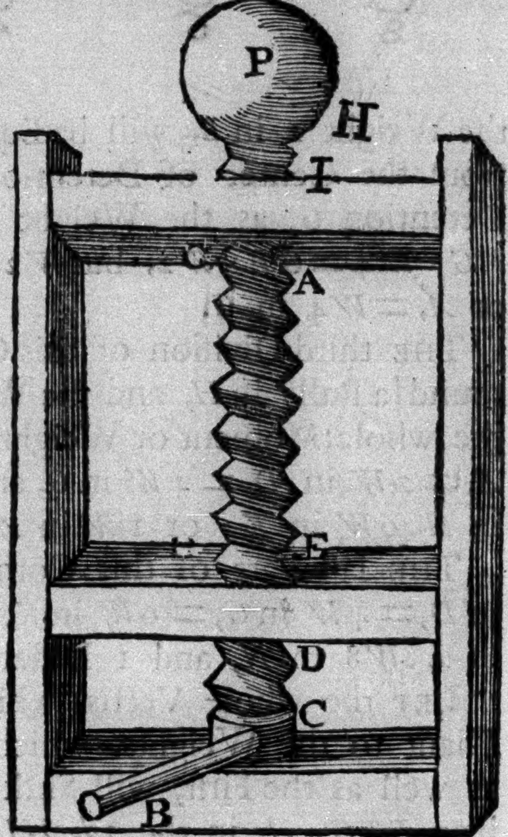
Mr. *Whiſton's* & Mr. *Hauksbee's* Experiments. Plate. 3, & 4.

AND to ſhew that this Account of the Trochlea, is the moſt Rational of any, which has been yet given, it ſupplies us with a Reaſon, why this Mechanical Power

Deviates from the Others in it's Proportions, for whilſt the Others are as the Diſtances from the ſame Center of Detention, this is as the Number of the Different Centers of it. Moreover it is manifeſt from the *1ſt* Figure, where the Trochlea Reſembles a Vectis, that if the oppoſite Fulcrums *D*, *G*, *K*, and *N*, were taken away, the Weights wou'd be rais'd at thoſe Points by the Power Acting at *B*; if therefore, as in the Pully, *Fig.* the *2d*, thoſe Fulcrums are replac'd in the Points above, and the Vectis is chang'd into a Cord, the Action muſt be perform'd by a Slideing of it, ſince the Fulcrums forbid it's Aſcent; which is a Phænomenon not Accounted for by the Preſent Mechanicks. We ſhall therefore conclude in Relation to this Power, that what we have to do with Reſpect to it, and the foregoing, is only to Determine at the End of theſe Mechanical Powers, what are the Forces of Material Beings at the ſeveral Diſtances from the ſame Center of Detention.

The Fourth Mechanical Power explain'd, which is that of the Cochlea or Screw.
Dr. Keill's Intr. ad Ver. Phyſ. Lect. 10.
Dr. Wallis de Motu, Cap. 9. Part 3. Vol. 1.
Sir Iſ. Newt. Princip. Leg. Corol. 2. & 6.

§. 33. The Fourth Mechanical Power is that of the Cochlea or Screw, the Interior has it's Spiral Indentations fill'd up by the Prominent Parts of the Exterior Screw, which are made Spiral likewiſe, and exactly correſpond to the Indentations of the Inward; or, which is the ſame in Effect, the Spiral Convexities of the Inward Screw anſwer to the Spiral Concavities of the Outward, and either the Outward Screw is fixt, and the Inward paſſes thro' the ſeveral Spirals of it, or elſe the Inward is fixt, and the Outward moves upon the Spirals of the Inward.



The Theorem made uſe of to Account for this Power.
Dr. Keill's Intr. ad Ver. Phyſ. Lect. 10. Theorem 14.

§. 34. The Theorem Introduc'd to Explain this Power is, that if the Ambitus, which the Force or Power apply'd Deſcribes in one Entire Circuit or Circumvolution of the Screw, is to the Interval of the two next Spirals, which Interval is to be computed according to the Length of the Screw, as the Weight or Reſiſtance to the Power, the Power and Weight will be Equally pois'd, and if there is the leaſt Addition to ſuch a Power, it will be capable of Moving the Weight; Let *CA* be the Interior Screw, *DE* and *AI* the Exterior ones, thro' which the Interior is forc'd by the Scytala or Handle *CB*, to which the Power is Apply'd, and by the Rotation of which the Weight *P* is rais'd; it is manifeſt by Obſerving the Motion of the Screw, that in one Revolution of it, the Weight is ſo much Elevated, as the Interval of the Two firſt Spirals, Expreſs'd by *HI*, Meaſures in a Perpendicular Length, and that the Power deſcribes at the ſame Time a Space Equal to the Ambitus, which it Delineates in one Revolution; that is, the Way or Space deſcrib'd by the Weight, is to that deſcrib'd by the Power, as the Interval of the Two Spirals, to the Ambitus of the Power, and conſequently, if the Power is to the Weight, as the Interval of the Spirals to the Ambitus of the Power, the Power and Weight will be Equal in their Forces, and if an Addition be made to the Power, it will be Superior to the Weight; that is, as before, if *P* is the Power, *G* the Weight, *V* the Velocity of the Power, *v* of the Weight, $PV = Gv$, or, $P.G::v.V$.

The First Objection againſt this Account.

§. 35. The whole Reaſoning of the preceding Section depends upon this, that whilſt *CB* performs it's Revolution, the Two Spirals *IH* appear above the Exterior Screw *IA*; Two Things therefore, will be neceſſary to be prov'd, to make this Demonſtration Juſt. Firſt, that Two Spirals of the Interior Screw, will always in their Elevation be exactly Correſpondent to the Ambitus, deſcrib'd by *CB*, which do's not ſeem to be certain, ſince, if the Spirals are made Cloſer to, or more Remote from each other, whilſt the Ambitus of the Scytala *CB* continues the ſame, they cannot have the ſame Relation to it; for Inſtance, if inſtead of 8 Spirals betwixt *A* and *E*, there ſhou'd be Double the Number, as 16, or half, as 4, it do's not appear to be Probable, that whilſt *CB* perform'd it's Ambitus, there ſhou'd be only Two Spirals, as *HI*, rais'd above the Exterior Screw, whether the Number of the Spirals in the Screw are 8, as in the Preſent Caſe, or 4 or 16, as in thoſe, which are ſuppos'd.

The Second Objection againſt it.

§. 36. Second, if this were Certain, that all Spirals were alike in their Proportion of Two of them to the Ambitus made by the Power, that is, that the Interval of Two Spirals only, be that Interval Greater or Leſs, was to be barely conſider'd, yet, ſince the Intervals wou'd be Different, as the Spirals were Cloſer or Wider, *HI* wou'd not have a certain and determin'd Proportion to the Ambitus of the Power, but wou'd be varied in a Thouſand Inſtances, and if ſo, the Ambitus of *B* continuing the ſame, and the Interval *HI* being Different, we cannot be from thence inform'd what Power will be ſufficient to raiſe the Weight *P*, when there is no ſettled Proportion betwixt the Ambitus of the Power, and the Interval of the Spirals. Nay, which is ſtill more, the ſame Power, performing the ſame Ambitus, wou'd be capable of raiſing Different Weights, for if the Ambitus of *B* is to *HI*, as 20.2, and the Power of *B*, as 1, it will be 2.1::20.10 the Weight, if the Ambitus *B* is to *HI*, as 20.4, and the Power of *B*, 1, it will be 4.1::20.5 the Weight, by which Means the ſame Power and Ambitus of it, will be able to Raiſe 10 or 5, or any other Number of Weights, which is Impoſſible. Beſides, *HI* is not the Way, or Space, which is deſcrib'd in Raiſing the Weight, but that which is perform'd by the Circumvolution of the Two Spirals, and therefore it cannot be, *B.P*::*HI*. Ambitus of *B*, which this Doctrine ſuppoſes.

Another Objection againſt this Account.

§. 37. Farther, it ſeems to be very Manifeſt, whatever the Proportion is betwixt the Ambitus of the Power, and the Interval of the Spirals, that whether there is a Weight, as *P*, plac'd at the Top of the Screw or not, upon one Revolution there will be the ſame Interval of the Spirals, and conſequently, that the Phænomenon of Raiſing the Weight do's not depend upon the Spaces deſcrib'd, but the Forces apply'd at *B*, which, if we likewiſe conſider, it will be impoſſible to adjuſt any Proportion betwixt them, and the Weight which is mov'd, unleſs we know what Proportion of a Man's Strength is Equal to ſo much Weight or Gravity.

A True Account of the Cochlea, or Screw.

§. 38. The neareſt to this Mechanical Power, if it may be term'd One, is the Axis in Peritrochio, excepting that the Circumvolutions are Spiral and Horizontal, and by the Screws not Retiring backward from the Nature of Heavy Bodies, Moving within one another, that ſuch Circumvolutions may be ſtopt and advanc'd at Pleaſure, and are not perform'd by Weights, but by Human Force and Strength.

Whereas the Gyrations of the Axis in Peritrochio are Circular, and Perpendicular to the Horizon, and Return back upon any Remiſſion of the Force apply'd to it, and tho' Human Strength is ſometimes us'd in this Mechanical Power, yet it may be Balanc'd by mere Weight and Gravity, as has been ſhewn in Reducing it to the Vectis. On the Contrary, let the Cochlea or Screw be plac'd in an Horizontal Poſition, what Weight or Weights will turn it round with any kind of Conformity to the Axis in Peritrochio, which Mechanical Power yet it moſt Reſembles? There is the Reſiſtance of Wood, or Iron, or Steel, Moving within it ſelf to be ſubdu'd, the Revolution not Circular but Spiral, and mere Gravity can only act in a Direct Line, which will be ſo far from Promoting the Revolution of a Spiral, that it will be an Impediment to it's Revolving.

From all which it ſeems to be Evident to me, that the Cochlea, or Screw, is to be Exterminated from the Number of Mechanical Powers, and that it is not Reducible to any of them; for let us now replace it in it's Proper Situation, that is, in a Perpendicular one to the Horizon, it is plain no Mechanical Force of Gravity, or any other Natural Power, beſides what is Imported from the Will and Strength of the Mind, can have any Effect upon it; but what the World has generally Eſteem'd Mechanical Power, is that which lies in Matter, Motion and Gravity, without any Interpoſition of an Animal or Arbitrary Agency.

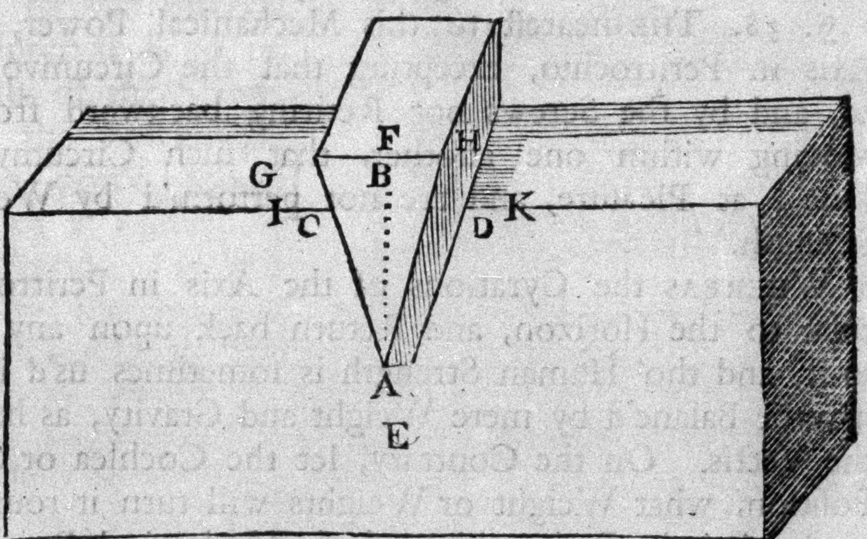
The Notion and Opinion therefore, which we may juſtly have of the Cochlea, or Screw, is this, that it is ſo far a Mechanical Power, as it has a Center of Detention with the Reſt, which is the Center of the Ambitus of the Scytala, but the Power made uſe of to the Moving of the Screw, is not Mechanical, unleſs a Human Force, of which there is no Eſtimation or Meaſure, may be accounted ſuch; ſo likewiſe the Paſſing of the Interior Screw, thro' the Exterior, meets with a Various Reſiſtance ariſing from the Nature of the Matter, thro' which it is Carry'd, and the Compreſſion made by it Differs, as the Human Force Apply'd, or the Renitency of the

Matter compreſs'd, Changes, Nothing of which has any Thing to do with Gravity or Mechaniſm, or is Reducible to any Laws of it.

AND as for the Screw it ſelf, it has no Power at all, excepting that of being mov'd Upwards or Downwards, by the means of the Scytala, and according to the Way, which lies open for it's Motion in a Spiral, and of ſuſtaining any Weight or Preſſure after it has acquir'd it's Poſition, by the Application of Human Force; the Reaſon of which is, becauſe the Gravity or Preſſure Acting in a Perpendicular upon the Screw, which can only move in a Spiral, faſtens and cloſes the Indentations of it, inſtead of putting them into Motion: But, if the Firſt entitles it to the Being a Mechanical Power, that is, it's Capacity of Moving Upwards and Downwards in a Way, which is Carv'd out on Purpoſe for it, a Cord drawn up and down thro' a Hole made for it's Motion, may be as well call'd a Mechanical Power; If the Laſt, that is, it's Capacity of ſuſtaining any Weight or Preſſure, after a Poſition acquir'd by the Application of Human Force, any Hard or Conſiſtent Body may be Term'd a Mechanical Power, which, when any Weight is laid upon it by the Application of Human Force, will ſuſtain it's utmoſt Preſſure, as fully as the Teeth of a Screw will do. So that we can ſee nothing more in the Cochlea, than a Center of Detention at one End of the Scytala, or Vectis, and the Application of a Human Force at the Other, by which the Screw will neceſſarily Riſe, and which therefore is all, which we need to conſider in this Power, or according to the Notion of Expanſive and Contractive Forces, there will be a Center of Detention or Contraction at the one Extremity of the Vectis, and an Expanſive Force at the Other.

The Cuneus, or Wedge, explain'd, which is the Fifth Mechanical Power. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 10. Theorem 15. Dr. Wallis de Motu, Cap. 12. Part 3. Vol. 1.

§. 39. THE laſt Mechanical Power to be Reſolv'd is, that of the Cuneus, or Wedge. The Theorem made uſe of to unfold this Power is, that the Power perpendicularly Apply'd to the Back of the Wedge, which ſhall be to the Reſiſtance to be ſurmounted by the Wedge, as the Thickneſs of the Wedge, to it's Heighth, will be of Equal Force with that of the Reſiſtance, and if ſuch a Power is increas'd, it will be Superior to, or an Over-balance for the Reſiſtance. For let the Reſiſtance to be over-comn by the Wedge, be the Firmneſs or Tenaciouſneſs of the Wood, or any other Body, whilſt the Wedge is Drove in as far as *A*, the Length, which the Power deſcribes is *B A*, and *D C* is the Space deſcrib'd by the Impediment, which is vanquiſh't and made to yield to the Force of the Power; for the ſame Reaſon alſo, whilſt the whole Length of the Wedge *F A*, penetrates to *E*, and deſcribes *B E*, the whole Breadth of it *G H*, deſcribes *I K* in the Impediment, and proportionally in it's Progreſs, as we take a greater or leſſer Part of the Cuneus, which is Evident from the Nature of the Triangle *G A H*, from whence the foregoing Theorem is ſuppos'd to be Manifeſt.



The Firſt Objection againſt the foregoing Account of the Cuneus.

§. 40. IN Anſwer to which we muſt affirm, that *F A* to *G H*, is ſaid, in the Theorem, to be as the Reſiſtance to the Power, when the Power and Reſiſtance are in an Equal Poiſe; whereas, this is prov'd, by ſuppoſing the Power to be Superior to the Reſiſtance, which is a Contradiction; for, if the Reſiſtance is Equal to the Power, it is altogether Impoſſible, that the Wedge ſhou'd ever Penetrate to *A*, or ſo much as enter the Impediment, altho' the preſent Demonſtration proceeds upon a Suppoſition, that it has enter'd the Impediment; if it be ſaid the Wedge may enter the Impediment, and after it is fixt in a certain Situation there, we are then to conſider it in an Equal Poiſe with the Reſiſtance, we muſt ask which way it came into that Situation, if by a Power Superior to the Reſiſtance, then the Power and Reſiſtance are not Equal. If it is farther told us, that the Power is ſuppos'd to be Augmented ſomething above the foregoing Proportion, to cauſe the Cuneus to move againſt the Impediment, that can have no Conſideration here, ſince the Forces, in the preſent Situation of the Wedge, are ſuppos'd to be Equal, having the Proportion aſſign'd by the Theorem, and yet this Situation of the Wedge, we ſay, cou'd not be, unleſs the Power was Superior to the Reſiſtance.

A Second Objection.

§. 41. MOREOVER, if we admit the Cuneus to be plac'd in the Poſition we now ſee it, if P and R repreſent the Power and Reſiſtance $P . R :: CD . BA$, but P and R by Suppoſition are Equal, therefore BA and CD are ſo likewiſe, which is Impoſſible in the preſent Figure, where the Height of the Triangle is not Equal to the Baſis; or which is the ſame to make $P = R$, they are to be as $CD . BA$, that is, one Leſs than the other; but if the Reſiſtance it ſelf is Greater than the Power, I don't ſee how the Way of the one or the other, will help the Latter.

A Third Objection.

§. 42. ANOTHER Objection againſt this Reaſoning is, that the Proportion of $P . R :: CD . BA$ is not Explain'd, that is, that the Power is to the Reſiſtance Reciprocally, as the Way of the Reſiſtance to that of the Power, for as we have juſt now ſaid, if the Power is Leſs than the Reſiſtance, it ſeems Inconceivable, how the longer the Way, which the Power is to go, ſhou'd make it Equal in it's Force to a greater Reſiſtance, which proceeds thro' a leſs Space; The Power and Reſiſtance will ſtill be, the one leſs than the other, and not Equal, ſo far as I am able to Imagine. If this Proportion is Aſſerted, becauſe it is preſum'd to be prov'd in the other Mechanical Powers, and particularly in the Vectis (for there is Nothing offer'd to explain it from the Power it ſelf), we firſt ſay, it is only Preſum'd, and not Prov'd, and in the ſecond Place, that if it were Prov'd in the Vectis, ſince there is no Analogy betwixt it and the preſent Power, it wou'd not be Conſequent, that ſuch a Reciprocal Proportion obtain'd here.

A Fourth Objection.

§. 43. IF there is a Similitude betwixt the Vectis and the Cuneus, the Center betwixt the Power and Reſiſtance deſerves to be fixt, and then the Reciprocal Proportion of Diſtance from ſuch a Center, which is ſo Intricate a Problem, as will Require a more accurate Reaſoning, than is here made uſe of, to ſolve.

A Fifth Objection.

§. 44. BESIDES the Three Firſt Powers are thoſe, which conſider the Forces, which Gravitate againſt them, but in the Preſent, not the Gravitation, but the Reſiſtance of a Body is to be overcomn; if therefore, by the ſame Fundamental Maxim of the Velocity of the Power being to the Velocity of the Weight, as the Weight to the Power, Reſiſtance is alſo to be Explain'd, and the Velocity of the Power is to the Velocity of the Reſiſtance, if we may ſo call it, as the Reſiſtance is to the Power, The Forces of Gravitation and Reſiſtance are the ſame, which no one has hitherto affirm'd, who do's not declare the Hardneſs of Marble, and it's Weight, to be Equivalent Terms.

A Sixth Objection.

§. 45. LASTLY, it is Notorious in Fact, that Bodies, which are Cleſt by a Wedge, by their own Force and Elaſticity, will ſometimes throw it out, when it has Penetrated to ſome Depth as A, and therefore, tho' the Wedge is Forc'd thither, after it has conquer'd it's Reſiſtance, and conſequently ſhou'd be in an Æquilibrium with it by this Demonſtration, yet is not, but is repuls'd by the Elaſtick Power of the Body; On the other Hand, where a Force is us'd to make the Wedge penetrate into other Bodies, as in ſoft or brittle Ones, it ſhall go farther into them by it's own Greater, or by the Leſs of the Bodies, which it Penetrates, than in Proportion to what was impreſs'd upon it; And laſtly, ſometimes Bodies will Cling to the Wedge with that Cloſeneſs, that the Reſiſtance will be Superior to the Power which forc'd it in; ſo little is there to depend upon ſuch Abſtracted Reaſonings, as theſe, to Explicate the full Powers of Nature.

AN Example of Each of theſe Phænomenons in Bodies we have, of the Firſt, in Metals, of the Second, in Clay, of the Third, in Wood, which eaſily ſeparates, and of the Fourth, in That, which has a more than ordinary Toughneſs.

A True Account of the Cuneus, or Wedge.

§. 46. WE have hitherto conſider'd the Cuneus, as a Mechanical Power, but this, as the Cochlea, or Screw, ſeems not properly to fall under that Denomination, and conſequently, that, truly ſpeaking, there are only Three, the Vectis, the Axis in Peritrochio, and the Trochlea.

FOR, as the Cochlea or Screw, the Cuneus likewiſe depends upon Forces, which are not Mechanical, and cannot be reduc'd to them, as the Human Force, and the

Force of Reſiſtance in Various Bodies; All therefore that can be ſaid, in Reſpect of this Power, ſo far as it can be thought to be Mechanical, is, that if a Force is apply'd Perpendicularly to *F*, or the Dorſum of the Wedge, *G*, *H*, and *A*, will obtain a greater Effect, the farther they are from *F*, againſt any Reſiſtance; ſo that in this Caſe, *F* is to be conſider'd as the Center of Detention, and *G*, *H*, and *A*, as the ſeveral Removals from that Center, which therefore will act with a Greater Force, as they are more Diſtant from it; and in this Property it agrees with the Vectis, which is the Standard of all Mechanical Powers; Thus, if *FA* repreſented a Lever, the farther the Power *F* is from *A*, the greater Moment it wou'd have, and if *FH*, or *FG*, repreſented a Vectis of Protruſion, or a Lever Protruding inſtead of Elevating, the more Remov'd *G* and *H* are from *F*, their Influences and Forces wou'd be the Greater, as the Line *FA*, on the contrary, wou'd have Little or None, being in this Reſpect a Line of Quieſcence, Contraction, or Detention.

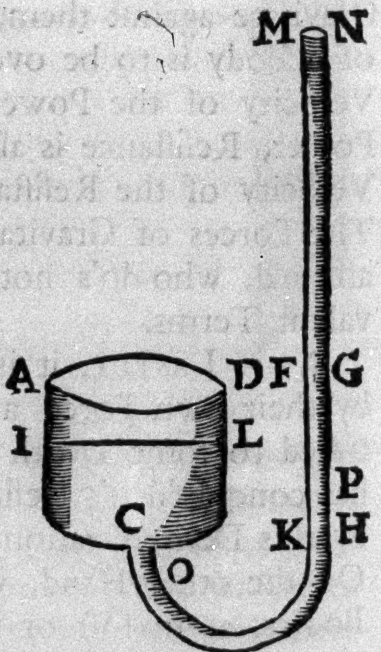
THUS far the Cuneus may be conſider'd as a Mechanical Power, but then it is not a Mechanical Power, that Gives an Action to the Cuneus, which is, what we Eſteem Eſſential to ſuch a Power; no Gravity, no Mechanical Force, or Action, has any Effect in the Wedge, and it's Power is wholly owing to a Human, Animal, and Expanſive Force.

WHAT therefore muſt be determin'd in Reſpect of this Mechanical Power is, that it is an Expanſive Force, acting in a Center of Detention or Contraction *F*, which Force of Expanſion, the Farther it is from the Center of Contraction, the Greater Influence and Power it has, conformable to what was before ſhewn in the Cochlea, or Screw.

THIS Power, conſequently, has not ſo great a Force, as the Former, becauſe, the one Acts in the very Center of Contraction, by which it is Enervated and Weaken'd, and the other at ſome Diſtance from it, by which it is more Vigorous and Strong.

The Inflected Syphon explain'd from the preſent Doctrine of Mechanicks. Dr. Keill's Intr. Theor. 15. Schol. Lect. 10. Rohault. Phyſ. Cap. 10. §. 11. Part 1. & Annotat.

§. 47. FROM the preſent Doctrine of Mechanicks is alſo Infer'd the Reaſon, why in the Inflected Syphon, whoſe Canals, or Arms, are of Unequal Capacities, the Water ſtands at an Equal Height, becauſe, if the Cylinder of Water *AILD* Deſcends, there muſt be an Equal Cylinder of Water Aſcend in the contrary Tube, as *MFGN*, but by the 15 Prop. El. 12. *Euclid.* the Baſes and Altitudes of Equal Cylinders are in a Reciprocal Proportion to each Other, that is, as *FM*. *AI* :: Orifice *AD*. Orifice *MN*, but *FM* is to *AI*, as the Velocity of the Water's Aſcent in the Leſſer Tube, is to the Velocity of the Water's Deſcent in the Larger, and the Orifice *AD* is to the Orifice *MN*, as the Water in the Cylinder *ACD* to that in *FKHG*, Becauſe Cylinders of Equal Heights are as their Baſes; from whence it follows, that the Velocity of the Aſcending Water *MF*, will be to that of the Deſcending *AI*, as the Water in the Canal *ACD* to that in *FKHG*, that is, the Velocities of the Waters in Each will be Reciprocally Proportional to their Quantities, and therefore their Moments Equal, but their Moments are Contrary, and therefore will produce an Æquilibrium, or Quieſcence.



The Firſt Objection againſt this Reaſoning.

§. 48. BUT in the firſt Place we have no Account, why the Water Stagnates in *COKH*, which is ſuppos'd to have no Part or Share in the Preſent Demonſtration, and yet *CO* may be as well preſum'd to riſe to *HP*, as *AI* to *FM*, whereas it is not thought neceſſary to prove, that the Water in *COKH* will be otherwiſe than in an Æquilibrium, and conſequently there is the ſame Reaſon, why *AI* ſhou'd not want any ſuch Proof; for if it is manifeſt, that *CO* will not riſe to *HP* an Equal Cylinder, it is as Evident, that *AI* will not riſe to *FM* an Equal Cylinder, or, which is the ſame, if the Surface or infinitely ſmall Cylinder *C* will not riſe in *KH*, it is as plain, that *AD* the Baſis of the Cylinder *AI*, or an infinitely ſmall Portion of it, will not riſe in *FG*, ſince *AD* is ſuppos'd to move at once, and by one uniform Depreſſion towards *IL*, and will therefore keep it's Station, as well as *FG*;

as therefore the true Cauſe, why the Surface *C* do's not Deſcend, nor *KH* Aſcend, is, that the Parts of Water are in an Equal Balance with one another, and obtain no Force or Moment in Relation to each, ſo the ſame Reaſon is Valid with Reſpect to the Surface *AD*, which will not Deſcend, not becauſe *FG* is, in ſuch a Caſe, to Aſcend to *MN*, but becauſe the Surface *AD* has really no Moment or Force, either in Reſpect of it's Parts with one another, or of any Subjacent ones, where *AD* and *FG* have their laſt Adjuſtments of their Gravities to the Earth by their Equal Diſtance from it.

A Second Objection.

§. 49. **Second**, the Aſcent and Deſcent of the Water is ſuppos'd to be Equal in this Demonſtration to the Surface, or ſmall Cylinder, *AD*, whereas, if one Part or Portion of *AD* cou'd be ſuppos'd to Deſcend, the Cylinders of Reciprocal Heights and Baſes wou'd be deſtroy'd, and the Reaſoning upon them, for tho' *AD* cou'd not Deſcend, by this Demonſtration, it wou'd not be from thence Evinc'd, that no Part of it cou'd; but the Suppoſition, which keeps one Part of the Cylinder *AD* from Deſcending, unleſs the Whole do's, namely, becauſe one Part or Portion has not a greater Power or Force of Deſcending than another, will keep the Whole from Deſcending in Reſpect of the other Surfaces, which are in an Æquilibrium with it, and conſequently, if *AD* do's not Deſcend, it is Manifeſt, that *FG* will not only not Aſcend to *MN*, but that it will not Aſcend at all; We may here add, that ſuppoſing the Velocities of the Parts in the Cylinders *ACD*, *FKHG* were Reciprocal to the Quantities of Matter in them, and therefore their Moments Equal, they wou'd not yet be Contrary, unleſs *FKHG* was carry'd in an Oppoſite Velocity to *ACD*, whereas it is ſuppos'd to have none, but what is Communicated from *ACD*, and therefore, if *ACD* is mov'd, muſt Tend the ſame Way.

A Third Objection.

§. 50. **Third**, let the Canals be never ſo Irregular, and let us contrive all the Imaginable, and moſt Diſagreeing and Different Shapes for them which we can, the Water in all the Canals will ſtand at the ſame Height, where it is permitted to do it, and yet it will be Impoſſible to reduce ſuch Figures to the Cylinders of *Euclid*, and the Reciprocal Proportions of thoſe that are Equal, upon which this Demonſtration depends, and which can be only accounted for from the Equal Moment, which the Parts of Water have amongſt one another; ſo little is there in ſuch Kind of Reaſonings, which yet carry with them the Appearance of Demonſtrations, becauſe certain Propoſitions in the Mathematicks are introduc'd to ſupport them, which ſtand much better in the Elements, from whence they are taken, than in the Philoſophy to which they are often, with too much Haſt, and too little Deliberation Apply'd.

Dr. Keill's Introduct. Theorem 15. Schol. Lect. 10.

As to Water or any other Fluid's paſſing from a Larger Channel, into a Smaller, with a Greater Celerity, that proceeds from a known Law in Mechanicks, that, where Water flows with a certain Force in a Larger Channel, if that Force is compreſs'd into a Narrower Space, it will be increas'd; and from which Law Sir *Iſ. Newton* argues againſt the *Vortices* of *Des-Cartes*, according to what we have before ſhewn in our *Principles of Philoſophy*.

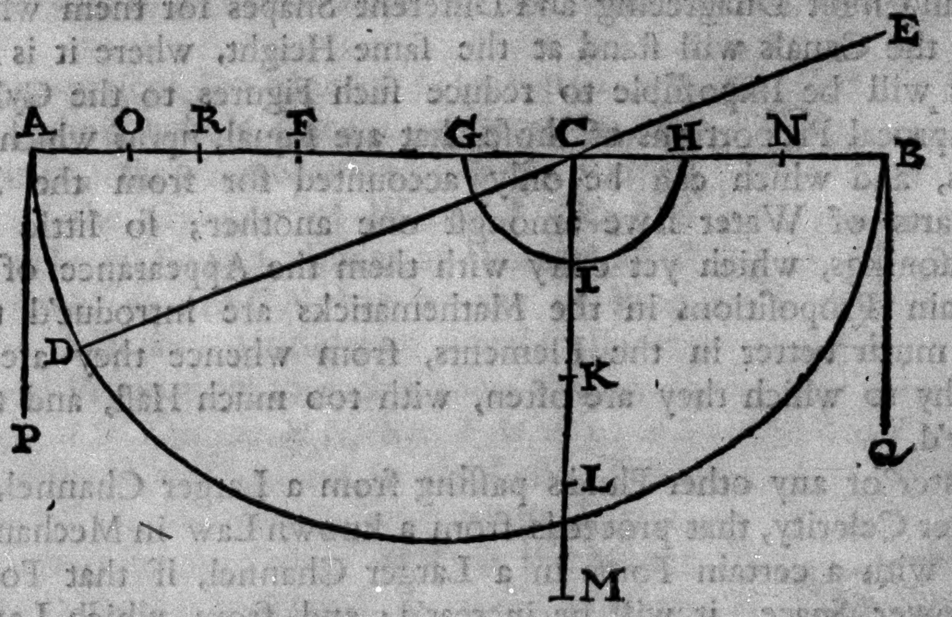
CHAP. V.

Concerning the Expanſive and Contractive Forces, Acting in a Center of Detention, or in any Diſtances or Removals from it.

The Doctrine of the Expanſive And Contractive Forces, Acting in a Center of Detention, or in any Removal from it, Explain'd, and the ſeveral Caſes Recounted.

§. 1. HAVING now gone thro' the Mechanical Powers, and ſhewn, that the Two Firſt, the Vectis and Axis in Peritrochio, are to be Eſtimated from their Diſtance from their Center of Detention, that is, that their Powers will be the Greater, the farther they are Remov'd from it, that the Third, which is the Trochlea or Pully, conſiſts of ſeveral Centers of Detention, by which the Force of that Power is weaken'd, that the Fourth and Fifth are not properly Mechanical Powers, but ſo far as they are, that the Cochlea or Screw conſiſts of a Center of Detention, with an Expanſive Force at Different Removals from it, and the Cuneus or Wedge of a Center of Detention or Contraction with an Expanſive Force Acting in that Center; We ſhall proceed, more particularly, to conſider theſe Centers of Detention, with the Various Diſtances from them, and the Expanſive and Contractive Forces plac'd in thoſe Diſtances, as alſo, what will reſult from a Complication of theſe Centers of Detention at Different Diſtances, with the Expanſive or Contractive Forces Acting in, or at a Diſtance from them.

LET AB be an Inflexible, ungravitating Line, and capable of being mov'd on the Center C, if any Weight, or other Force, is apply'd to A or B, it is manifeſt a Motion will be produc'd round the Point C, which I call the Center of Detention, becauſe it is not a Center of Gravity, on which Forces are Equally pois'd, which is only one Caſe of the Center of Detention, but a Center, by which the Forces depending at A or B, are kept and detain'd from Receding from it, and which, if the Forces at A and B, computing their Diſtances, are Equal, will be, what is call'd a Center of Gravity.



Caſ. 1. IF therefore any Point, or little Body, as a Minute Globe of Similar and Homogeneous Matter, which has a certain Force of Gravitation, be plac'd in the Center C, it will be hinder'd from Deſcending, and will remain Quieſcent in the Point of Detention; Let the ſame Gravitating Point, or Force, be remov'd one Point or Line towards A or B, ſuppoſing to G or H, it will then Deſcend, but ſince it cannot Recede from the Center of Detention C, it will deſcribe the Arch of a Circle round it, which Arch will be Greater or Leſs, according to the Force of Gravitation; thus, if it has the Force of CI, it will Deſcend from G to I, if of CK, or double the Force of the Former, ſince it cannot Deſcend to K, it will ſpend the Remainder of it's Force IK, above that of CI, in Riſing towards H, and Deſcending from thence to I, and then Riſing towards G, till it's Force IK is conſum'd in Reciprocal Oſcillations.

IF the Gravitating Force is CL, or Triple of the Former, or CM, which is Quadruple of it, the Oſcillations will riſe higher towards H and G, and if this Gravitating

Force is ſtill increas'd to a Centuple or Millecuple Proportion of the Former, the Oſcillations will be chang'd into entire Revolutions, which will not Ceaſe about the Center of Detention, till the whole Gravitating Force is Conſum'd and Exhauſted, and if ſuch Gravitating Force is Permanent and Conſtant, the Revolutions will be Uninterrupted and Continual, from whence it is Evident, that there is nothing more Requiſite to ſuch Revolutions, than the Gravitating Force only, without any Projectile one, That is, than an Expanſive, which the Gravitating here Repreſents, and a Contractive, which Exerts it ſelf in the Center of Detention; or *Vice Verſâ.*

Caſ. 2. If now the Gravitating Point, or Little Body, of Similar Matter, ſhou'd be remov'd from the Center of Detention, Two, Three, Four, or a Hundred, or a Thouſand, or a Million of Points, or ſmall Lines, from the Center of Detention, all Things wou'd happen as before, in Reſpect of the Oſcillations or Revolutions of it, excepting that the Force of it wou'd be increas'd, the farther it retir'd from ſuch a Center, in which it's Force was entirely Hinder'd and perfectly Quieſcent; For, if the ſame Gravitating Force, which in the Center of Detention is Quieſcent, is apply'd to one Diſtance from it, it is Reaſonable to think, that it will have one Effect more than it had before, which was none, that, at Two Diſtances, it will have a double Effect, and ſo on; that is, any certain Gravitating Force will be increas'd in it's Energy or Expanſive, in Proportion, as it departs from the Center of Detention or Contraction, which prohibits any Effect of it; and we may the more eaſily acquieſce in this Reaſoning, becauſe it is confirm'd by Experience, and by the Preſent Mechanicks, for if the ſame Force of Gravitation is Greater at *A*, than it is at *B*; in Proportion to their Diſtances from the Center of Detention, it will neceſſarily follow, that the ſame Gravitating Force at the Diſtance *AC*, will be Equal to that at the Diſtance *CF*, or *BC*, ſuppoſing the Sum of the ſame Gravitating Forces at *B*, to that of *A*, is as the Diſtance of *A* from the Center of Detention *C* to that of the Diſtance of *F* or *B* from the ſame Center.

Caſ. 3. If now an Expanſive Force, which is impreſs'd, for hitherto we have only conſider'd the Gravitating or Contractive, is ſuppos'd to Act in the ſame Point *C*, which is a Center of Detention, as if we ſtrike with a Violent Force upon it, it's Effect will be Greater than that of a Gravitating, and may ſpread and diffuſe it's Action towards *H* and *G*, ſince it's Progreſs is ſtopt in *C*, by it's being ſuppos'd a Center of Detention, tho' without any actual Motion of the Line *AB*; Let the Force of Percuſſion be ſtill increas'd in the Point of Detention *C*, and the Action will be the Greater, which is communicated along the Lines *CF*, *CB*, but yet without any Motion of them.

Let now the Force of Percuſſion or Expanſion exert it ſelf, one Remove from the Center of Detention, in *G* or *H*, upon the Gravitating Point, and it will give an Additional Force to it, and aſſiſt to the producing Greater Oſcillations, or Entire Revolutions, and let the Force of Percuſſion be ſtill Increas'd, and the Effect will be ſtill the Greater; For the Contractive Force or the Gravitating, in Reſpect of *C* the Center of Detention, is an Expanſive one, by which it Endeavours to retire from the ſaid Center, and conſequently, the Force of Percuſſion acts, in this Caſe, in Conjunction with it, being likewiſe an Expanſive one Impreſs'd, and therefore promotes and advances the ſame Effect, and is the Projectile of this Philoſophy.

Caſ. 4. If the ſame Expanſive Force impreſs'd, or Force of Percuſſion is remov'd, Two, Three, Four, or a Hundred, or a Thouſand, or a Million of Points, Lines, or Diſtances from the Center of Detention *C*, it will be in Proportion augmented, and for the ſame Reaſon, as the Gravitating or Contractive, which in the preſent Circumſtance has the Nature of an Expanſive. We here call the Force of Percuſſion an Expanſive Impreſs'd, to diſtinguiſh it from the Intrinſick Expanſive, which we ſhall afterwards Conſider, for of the Two Intrinſick Forces of Matter, the Contractive or Gravitating is here only alledg'd.

From what foregoes it is Evident, that the Forces, or Moments, or Powers of Bodies, which have a Contractive or Gravitating Force, and one of Percuſſion, and which Act from a Center of Detention are Greater, the Greater that Gravitating Force is, the Greater the Sum or Quantity of it is, the farther it is remov'd from the Center of Detention, and the Greater the Expanſive Force which is Impreſs'd, and the farther it's Diſtance is from the ſame Center. If therefore, *M*, *m* are made to repreſent the Moments of ſuch Bodies acting upon a Center of Detention; *C, c* the Contractive or Gravitating Forces; *A, B* the Sums or Quantities of them; *R, r* the Diſtances or Removals from the Center; and *P, p* the Percuſſions or Expanſive Forces Impreſs'd; the following Theorems will be certain.

Theorem the Firſt of this Doctrine, and it's Corollaries, That the Moments of Bodies, which have a Force of Contraction or Gravitation and Percuſſion, and which Act from a Center of Detention, are in a Direct Reaſon of the Forces of Gravitation or Contraction, of the Quantities or Sums of thoſe Forces, of the Forces of Percuſſion, and of the Diſtances from the Center of Detention.

§. 2. THEOREM the Firſt is, That the Moments of Bodies, which have a Force of Contraction or Gravitation, and Percuſſion, and which Act from a Center of Detention, are in a Direct Reaſon of the Forces of Gravitation or Contraction, of the Quantities or Sums of thoſe Forces, of the Forces of Percuſſion, and of the Diſtances from the Center of Detention, that is, $\frac{M}{m} = \frac{ACPR}{Bcpr} = \frac{A}{B} \times \frac{C}{c} \times \frac{P}{p} \times \frac{R}{r}$; From whence it Enſues.

Corol. 1. IF $A = B$, $\frac{M}{m} = \frac{CPR}{cpr} = \frac{C}{c} \times \frac{P}{p} \times \frac{R}{r}$, or $M.m::CPR.cpr$, or, if the Quantities of the Gravitating or Contractive Forces are Equal, the Moments of ſuch Bodies will be as the Forces, the Percuſſions, and the Diſtances or Removals from the Center of Detention.

Corol. 2. IF $C = c$, $\frac{M}{m} = \frac{APR}{Bpr}$, or, if the Gravitating or Contractive Forces are Equal, the Moments of ſuch Bodies will be as the Sums or Quantities of the Forces, the Percuſſions, and the Diſtances or Removals from the Center.

Corol. 3. IF $P = p$, $\frac{M}{m} = \frac{ACR}{Bcr}$, or, if the Percuſſions are Equal, the Moments of theſe Bodies will be as the Gravitating or Contractive Forces, the Sums of them, and their Removals from the Center.

Corol. 4. IF $R = r$, $\frac{M}{m} = \frac{ACP}{Bcp}$, or, if the Diſtances from the Center are Equal, the Moments of the preſent Bodies, will be as the Gravitating or Contractive Forces, the Sums or Quantities of them, and the Percuſſions.

Corol. 5. IF $A = B$, and $C = c$, $\frac{M}{m} = \frac{PR}{pr}$, or, if the Gravitating or Contractive Forces are Equal, and the Sums or Quantities of them, the Moments of theſe Bodies will be as the Percuſſions, and their Removals from the Center.

Corol. 6. IF $A = B$, and $P = p$, $\frac{M}{m} = \frac{CR}{cr}$, or, if the Quantities or Sums of the Gravitating or Contractive Forces, and the Percuſſions are Equal, the Moments of ſuch Bodies will be as the Gravitating Forces, and their Removals from the Center; and if $C.c::R.r$, $M.m::R^2.r^2$. ſee *Corol.* 8.

Corol. 7. If $A = B$, and $R = r$, $\frac{M}{m} = \frac{CP}{cp}$, or, if the Sums or Quantities of the Forces, and the Removals from the Center are Equal, the Moments of the Bodies will be as the Gravitating or Contractive Forces, and the Percuſſions.

Corol. 8. IF $C = c$, and $P = p$, $\frac{M}{m} = \frac{AR}{Br}$, or, if the Gravitating or Contractive Forces, and the Percuſſions are Equal, the Moments of the Bodies will be as the Sums of thoſe Forces, and their Removal from the Center, which is the Caſe of the Vectis, and of the Mechanical Powers, ſo far as they are Reducible to it, and which from what has been ſaid are but illy Explain'd, and Accounted for, by an Abſtracted Reaſoning, and without the Real Forces here aſſerted. And if *A* and *B*, as in *Corol.* 6. are Equal, and the Forces of Gravity are increas'd in Proportion to their Diſtance from the Center of Detention, $\frac{M}{m} = \frac{R^2}{r^2}$, or the Gravitating Forces will be as the Squares of the Diſtances from the Center of Detention, and therefore, ſince they they have the Nature of an Expanſive from it, their Forces towards that Center will be Reciprocally, as the Squares of the ſaid Diſtances, which is a Celebrated Propoſition in the preſent Phyſical Aſtronomy, and which is affirm'd to be the Law, by which the Planets Gravitate towards the Sun.

Corol. 9. If $C=c$, and $R=r$, $\frac{M}{m}=\frac{AP}{Bp}$, or, if the Gravitating or Contractive Forces, and their Removals from the Center are Equal, the Moments of the Bodies will be as the Sums or Quantities of thoſe Forces, and as the Percuſſions.

Corol. 10. If $P=p$, and $R=r$, $\frac{M}{m}=\frac{AC}{Bc}$, or, if the Percuſſions and the Removals from the Center are Equal, the Moments of the Bodies will be as the Gravitating or Contractive Forces, and the Sums or Quantities of them.

Corol. 11. If $A=B$, $C=c$, and $P=p$, $\frac{M}{m}=\frac{R}{r}$, or, if the Gravitating or Contractive Forces, the Sums or Quantities of them, and the Percuſſions are Equal, the Moments of the Bodies will be as the Diſtances or Removals from the Center.

Corol. 12. If $A=B$, $C=c$, and $R=r$, $\frac{M}{m}=\frac{P}{p}$, or, if the Gravitating or Contractive Forces, the Sums or Quantities of them, and their Removals from the Center are Equal, the Moments of the Bodies will be as the Percuſſions.

Corol. 13. If $C=c$, $P=p$, and $R=r$, $\frac{M}{m}=\frac{A}{B}$, or, if the Gravitating or Contractive Forces, the Percuſſions, and the Removals from the Center are Equal, the Moments of the Bodies will be as the Sums or Quantities of thoſe Forces.

Corol. 14. If $A=B$, $P=p$, and $R=r$, $\frac{M}{m}=\frac{C}{c}$, or, if the Sums or Quantities of the Gravitating or Contractive Forces, the Percuſſions, and the Removals from the Center are Equal, the Moments of the Bodies will be as the Gravitating or Contractive Forces.

Corol. 15. If $M=m$, $ACPR=Bcpr$, and $A.B::cpr.CPR$, or, if the Moments of the Bodies are Equal, the Sum or Quantity of the Gravitating or Contractive Forces will be in a Reciprocal Proportion of thoſe Forces, of the Percuſſions, and the Removals from the Center.

Corol. 16. If $M=m$, $ACPR=Bcpr$, and $C.c::Bpr.APR$, or, if the Moments of the Bodies are Equal, the Contractive or Gravitating Forces will be in a Reciprocal Proportion of the Sums or Quantities of ſuch Forces, of the Percuſſions, and Removals from the Center.

Corol. 17. If $M=m$, $ACPR=Bcpr$, and $P.p::Bcr.ACR$, or, if the Moments are Equal, the Percuſſions will be in a Reciprocal Proportion of the Gravitating or Contractive Forces, of the Quantities or Sums of them, and of their Removals from the Center.

Corol. 18. If $M=m$, $ACPR=Bcpr$, and $R.r::Bcp.ACP$, or, if the Moments are Equal, the Diſtances or Removals from the Center are in a Reciprocal Proportion of the Gravitating or Contractive Forces, the Sums of them, and the Percuſſions.

Corol. 19. If $M=m$, that is, $ACPR=Bcpr$; $AC.Bc::pr.PR$, and $AP.Bp::cr.CR$, and $AR.Br::cp.CP$.

Corol. 20. If $M=m$, and $A=B$, $CPR=cpr$, and $C.c::pr.PR$, or $P.p::cr.CR$, or $R.r::cp.CP$; That is, if the Moments are Equal, and the Sums of the Gravitating or Contractive Forces are ſo too; The Forces will be in a Reciprocal Proportion of their Removals from the Center, and of the Percuſſions; The Percuſſions, in a Reciprocal one of the Forces, and of their Removals from the Center; and the Removals from the Center, in a Reciprocal one of the Percuſſions, and of the Forces.

Corol. 21. If $M=m$, and $C=c$, $APR=Bpr$, and $A.B::pr.PR$, and $P.p::Br.AR$, and $R.r::Bp.AP$.

Corol. 22. If $M=m$, and $R=r$, $ACP=Bcp$, and $A.B::cp.CP$, and $C.c::Bp.AP$, and $P.p::Bc.AC$.

Corol. 23. If $M=m$, $A=B$, $C=c$, $PR=pr$, and $P.p::r.R$, or, if the Moments are Equal, the Sums of the Contractive Forces, and the Forces, the Percuſſions will be in a Reciprocal Proportion of their Diſtances from the Center.

Corol. 24. If $M=m$, $A=B$, $P=p$, $CR=cr$, and $C.c::r.R$, or, if the Moments are Equal, the Sums of the Contractive Forces, and the Percuſſions, the Forces will be in a Reciprocal Proportion of their Diſtances from the Center.

Sir Iſ. Newt. Princ. Prop. 8. Theorem 8. Part 3. Edit. 2. Corol. 3. & 4.

Thus a Globe of pure Lead, Iron, Wood, or Wool, without any Pores or Vacuities, will be Equal in it's Moment and Weight to a Globe of Gold of the ſame Diameter, without any Pores or Vacuities, if ſo much, as the Gold is Heavier, by ſo much farther the Globe of Lead, Iron, Wood, or Wool, be Remov'd from the Center of Detention; Thus alſo the Planets, the Nearer they are to the Sun, the Denſer they are, and the Farther they are Remov'd from it, the Rarer; *Jupiter* is Denſer than *Saturn*, the *Earth* than *Jupiter*, the *Moon* than the *Earth*, and *Mercury* than Either; but this Denſity ſuppoſes all Matter to have the ſame Gravitating Force, and only the Parts of it to be more Conſtipated, whereas the preſent Corollary ſuppoſes the Gravitating Forces to be Different, and that the Matter of *Jupiter* is intrinſically Heavier than that of *Saturn*, that of the *Earth* than that of *Jupiter*, and that of *Mercury* than that of the *Earth*, or the *Moon*, by which, according to this Corollary, their Moments will be Equal, and the Æquilibrium of the Planetary Syſtem will be preſerv'd.

Corol. 25. If $M=m$, $A=B$, $R=r$, $CP=cp$, and $C.c::p.P$, or, if the Moments are Equal, the Sums of the Forces, and the Diſtances from the Center, the Forces will be in a Reciprocal Proportion of the Percuſſions.

Corol. 26. If $M=m$, $C=c$, and $P=p$, $AR=Br$, and $A.B::r.R$, or, if the Moments are Equal, the Forces, and the Percuſſions, the Sums or Quantities of the Forces will be in a Reciprocal Proportion of the Diſtances or Removals from the Center, which is the Caſe of the Vectis, when the Weights are in an Equal Balance, that is, 1 *l.* of Lead at 5 Removes from the Center, will be Equal to 5 *l* at 1 Remove from it; And if we take in the Intrinſick Forces Themſelves, that is, if $M=m$, $P=p$, ACR will be $=Bcr$, according to which it is not Impoſſible, but it may have pleas'd Almighty God to adjuſt the Situations and Poſitions of the Heavenly Bodies, ſo that the Intrinſick, Innate, and Different Gravities of *Mercury*, *Venus*, the *Earth*, of *Mars*, *Jupiter*, and *Saturn* into their Diſtances and Bulks, ſhou'd be Equal, by which there wou'd be a perfect Balance amongſt them, and if the leaſt Increas'd on the one Hand, or the other, there wou'd be a Preponderancy, and conſequently, a Revolution; but of this we ſhall ſay more at the End of theſe Corollaries.

Corol. 27. If $M=m$, $C=c$, and $R=r$, $AP=Bp$, and $A.B::p.P$, or, if the Moments are Equal, the Contractive Forces, and the Removals from the Center, the Sums of the Forces will be in a Reciprocal Proportion of the Percuſſions.

Corol. 28. If $M=m$, $P=p$, $R=r$, $AC=Bc$, and $A.B::c.C$, or, if the Moments are Equal, the Percuſſions, and the Removals from the Center, the Sums or Quantities of the Forces will be Reciprocally as the Forces; thus, if Gold is 19 Times Heavier than Water, 19 Parts of Water will be Equal, in their Moment, to 1 of Gold, ſuppoſing no Pores or Vacuities in them; and thus, if the Planets revolv'd at Equal Diſtances from the Sun, and their Moments were Equal, their Gravitating Forces wou'd be Reciprocally, as their Quantities or Sums.

The Laws of Percuſſion hitherto conſider'd in Conjunction with the Gravitating Force, in Obedience to the Preſent Philoſophy, which joins a Gravitating with a Projectile.

§. 3. I have hitherto conſider'd the Laws of Percuſſion, in Conjunction with the Force of Gravitation, in Obedience to the Preſent Philoſophy, which unites a Projectile with it, which indeed it found neceſſary to do, becauſe, it was by Means of the Projectile, that the Gravitating Force was ſuſtain'd from falling to the Center, and by the Gravitating Force, that the Projectile was detain'd from flying off in a Tangent; The Projectile therefore ſeems to have been a mere Invention only, to keep the Gravitating Forces in Action, which otherwiſe wou'd have immediately Tumbled to the Center, and to ſupport the whole Syſtem, which wou'd have been Ruin'd at once, rather than any Force, which is Obſervable in Nature, or has it's Foundation in the Exiſtence of Things.

The Revolutions of Bodies accounted for by a Gravitating Force without a Pro-

§. 4. On the Contrary, in the Way, which we go, of Conſidering Bodies, Acting with a Force of Gravitation, round a Center of Detention, we have no Occaſion for ſuch Projectile Forces, or of any Percuſſions, which, as we have ſhewn, only Tend to promote and increaſe the Effect of Gravitation, and which we ſhall therefore now Diſmiſs, nor do we make uſe of any other Forces, than what, on all *jectile, which, when ſpent, wou'd leave them Quieſcent.*

Hands, are acknowledg'd, and are apparent in every Common Vectis or Pendulum, all that we require is, that, if there are Gravitating Forces, which are Capable of deſcribing Oſcillations round a Center of Detention, there may be ſuch a Proportion of thoſe Forces in themſelves, and by their Removal from the Center of Detention, which ſhall carry the Body round in Entire Revolutions; The Tendency of all Bodies to the Earth hinders this in the Vectis, and in Pendulums; But let us now ſuppoſe a Body, which has a Contractive or Gravitating Force in it ſelf and which it wou'd exert if it approach'd near to other Bodies, Plac'd at an Immenſe Diſtance from all Material Beings whatſoever; It cou'd not Deſcend, nor cou'd it Aſcend, nor Move one Way or Another, becauſe there is nothing to determine it to any Side or Part of Space, and it wou'd remain perfectly Quieſcent in the vaſt Expanſe, Immoveable in it ſelf, and obey the Power of it's own Contractive and Reſiſting Force to Motion; If any Projectile Force ſhou'd be Communicated to it, the Effect wou'd be, that it wou'd Roll on in Space that Way, to which the Projectile Force determin'd it, and when that Impreſs'd Force was ſpent, wou'd be again Quieſcent; which wou'd be the Caſe of the Earth and Planets, Acted by a Temporary, Finite, and a Projectile Force, and as for an Infinite one, we ſhall afterwards ſhew there is no ſuch Affirm'd, when we come to Inquire into the Phyſical Aſtronomy.

Yet let this Contractive, Quieſcent, and Gravitating Force be plac'd at the End of an Inflexible Line or Balance, namely, at *A* in the preceding Figure, and another Equal to it at *B*, at Different Diſtances from the Center of Detention *C*, the Firſt wou'd Preponderate the Laſt, and deſcend to *D*, whilſt the other ris' to *E*, upon the very Account that they have Moments and Forces at Different Diſtances from the ſame Center, and ſince there is no Tendency to the Earth, or any other Body to hinder this Motion, it wou'd continue for Ever in a Conſtant Revolution, For *D* has the ſame Preponderancy to *E*, in this Situation, as *A* had to *B*, in the Former, having the ſame Relation to the Point or Center of Detention *C*, as before.

If therefore now the Force at *B* and *E* is taken off, *A* and *D* will ſtill have a Greater Force of Revolving round the ſame Center, there being nothing to prohibit or retard it's Motion, either from *B* or *E*, or from the Earth, or any other Body, it being only conſider'd with Relation to it's Center of Detention, from which by it's own proper Gravitating Force it wou'd Recede, but is confin'd to it, by the imagin'd and inflexible Line *AC*; It muſt be farther obſerv'd, that as the Forces at *A* and *B*, are the ſame in reſpect to their Center of Detention, whether they act from *A* or *B*, or from *P* and *Q*, in a Common Balance, where the Force acts Perpendicularly to the Earth, that is, at the ſame Diſtances from that Center, ſo is it in Reſpect of the Celeſtial one, for the Forces will be the ſame in every Part of the ſeveral Orbits, where they are Equidiſtant from it.

Why the Planets Revolve the ſame Way.

§. 5. Let *H* repreſent *Mercury*, *N*, *Venus*, and *B*, the *Earth*, on one Side of the Balance, *R*, *Mars*, *O*, *Jupiter*, and *A*, *Saturn*, on the other, and let *C*, the Center of Detention, repreſent the *Sun*.

It is Manifeſt, if theſe Planets are with their Diſtances from the Center, and their Innate Forces in an Æquilibrium, at *A*, *O*, *R*, *H*, *N*, *B*, they will be ſo in every other the ſame Diſtance from *C*, and therefore wou'd be Quieſcent, but ſince they are not Quieſcent, the Planets at *A*, *O*, and *R*, that is, *Saturn*, *Jupiter*, and *Mars*, do Preponderate thoſe at *B*, *N*, and *H*, namely, the *Earth* with it's *Moon*, *Venus* and *Mercury*, and by Conſequence, all of them revolve the ſame Way, from Weſt to Eaſt, that is, from *A* to *D*, and from *B* to *E*, a Phænomenon, which has not been yet ſolv'd, no more than that of their Revolutions.

That Revolutions ſhou'd be perform'd, and that they ſhou'd be perform'd the ſame Way, is Manifeſt from this Doctrine, as alſo that a Revolution may be perform'd by one Gravitating Body only about a Center of Detention, as that of the *Moon* about the *Earth*, which therefore is a Conviction of the Truth of ſuch a Doctrine, that we find it ſo in Fact, and of the Comprehenſiveneſs of it, that it ſolves thoſe Phænomenons, an Account of which has been hitherto ſo much Deſpair'd of, that it has ſcarcely been Attempted, and which yet we ſhall now Propoſe another Way.

Another Way of Explaining the Revolutions of the Planets.

§. 6. If *A* Preſſes, Acts, or Gravitates towards *B*, with a Force or Moment, which is compenſated by an Equal Action, Gravitation, or Preſſure of *B* towards *A*, *A* and *B* will remain Quieſcent, their Mutual and Equal Moments being ſupported and

balance'd

balance't by each other; But, if *A* Acts or Preſſes with a Greater Force or Moment towards *B*, than *B* towards *A*, the Exceſs of the one Force above the other, will cauſe a Conatus; or endeavour in *A* to approach towards *B*, which ſince it cannot be Effected in the Direct Line *A B*, which is ſuppos'd Inflexible, it will (as all other Actions of Bodies vent themſelves that Way, where there is the leaſt Reſiſtance to them) Exert it ſelf Side-ways, for Inſtance, towards *D*, whilſt *B* recedes to *E*, ſo as to preſerve the ſame Diſtance from *C*, which Action ſtill Continuing the Effect will be Continu'd, and Revolutions Perform'd by it; And if *B* is taken away, *A* Preſſing or Acting towards *C*, and not finding a Paſſage for it's Action, will Exert it ſelf Side-ways to *D*, and by that Means revolve round the Center, which it Endeavours to approach.

THIS cannot obtain in Bodies which Gravitate to the Earth, ſo as, being ſtopt at the Surface, they ſhou'd revolve round it, by an Exertion of their Action Side-ways, becauſe they have not an Exceſs of Gravity above other Bodies, but are nearly in an Equal Balance with them, and therefore muſt be Quieſcent, however, that there is ſome Action Side-ways upon their being ſtopt at the Surface, is Evident from almoſt all Bodies dropt Perpendicularly to it, which, more or leſs, are thrown, from the Place where they fall, into a Lateral Direction.

As alſo the Surface of the Earth it ſelf (and the ſame may be ſaid of the other Planets) recedes Laterally by this Side-Action or Preſſure, where the Direct cannot obtain, and by that Means it and all the Planets are Revolv'd about their Axes the ſame Way, and upon the ſame Principles, as their ſeveral Gyrations in their Orbits are Perform'd, which is another Phænomenon, not in the leaſt Explain'd, by the Phyſical, or any other Aſtronomy.

Why the Orbits of the Planets are Elliptical.

§. 7. FROM hence likewiſe it is Manifeſt, That the Orbits of the Planets will be Elliptical, and that they are deſcrib'd in the Periheliums with a Greater, and in the Apheliums with a Leſs Velocity; For the Force or Gravitation at *A*, ſtill Preſſing more and more towards *C*, ſuppoſing the Line *A C* not to be wholly Inflexible, becomes continually ſhorter, till the Planet arrives at the Perihelium *B*, where it obtains it's utmoſt Preſſure and Approach towards *C*, and from thence is again Weaken'd and Diminiſh't to it's Return in *A*, and conſequently, where the Force is Stronger, it will be carry'd with a more Intenſe, and where Diminiſh't and Weaker with a more Remiſs and Languid Velocity.

THUS, if inſtead of the Inflexible Line, we ſubſtitute an Expanſive or Repulſive Force in the Sun, which may be as juſtly allow'd, from the Planets not falling Directly to it by their proper Gravitation, as that there is a Gravitating Force in Bodies to each other, tho' at ſeveral Thouſand Miles Diſtance, and from the very Nature of that Body, which Exerts it ſelf in an Expanſive Force of Light and Heat, the Repulſive or Expanſive Force from *C*, falling directly upon *A*, prohibits any nearer Approach to it, which therefore Preſſing towards *D*, and meeting with an Obliquity of the Expanſive Force from *C*, and which is thereby weaken'd, it Approaches nearer to the Center, till at Length, by it's utmoſt Efforts, it arrives at *B*, the Neareſt it can to *C*, but there being a Direct Action from *C*, the Contractive or Gravitating removes to a Weaker, and more Oblique of the Expanſive *E*, and ſo Revolves to *A*. The Center of this Expanſive Force is the Center of Detention, by the Endeavours of the Gravitating to Approach to it.

Dr. Greg. Aſtron. Lib. I. Prop. 66. 67, 68.

HE who will Impartially weigh, and conſider what I have writ, and compare it with *Kepler*'s Phyſical Account of theſe Matters, will perhaps find the Principles, I have propos'd, are more Rational, and leſs Romantick than his, who yet was the firſt Author of this Doctrine, into which we now Examine, nay, I may farther add, are juſtify'd by Nature, and by Fact, and a fair and ſincere Reaſoning upon them.

BUT if what I have offer'd may be more liable to Exception, upon the Expanſive Force introduc'd in this Account, to ſupply the Place of a Vectis or Inflexible Line, it will come to the ſame, If we ſuppoſe a Force of Attraction in the Sun, or in the Center of Detention in a Vectis, and a Centrifugal one in *A*, by Endeavouring to depart from that Center, by it's Proper Force of Contraction and Gravitation, which Terms, perhaps, will be more Eaſily admitted, according to the preſent Current Opinions in Philoſophy, tho', in Truth and Reality, they are not Different from what I have mention'd. Having therefore given an Account, as far as we cou'd in ſo ſhort a Compaſs, of the Cauſes of the Revolutions of the Planets, under the Direction and Providence of God, who Eſtabliſhes his own Laws, by which all Nature ſhall Move and be Acted, We now Return to our Proportions of theſe Forces.

A Computation of the Gravitating Forces of the ſeveral Planets from this Doctrine.

§. 8. THE Proportions of theſe Forces are, what we are next to Determine, in the Computing of which we conſider C to be a Center of Detention, and the Moments of the Planets to be $\frac{M}{m} = \frac{ACR}{Bcr}$, and M to be $= m$, and therefore $ACR = Bcr$. See *Corol.* 8. 24. 26. preced. Theorem.

THUS, ſuppoſe the Diſtances of *Mercury*, *Venus*, the *Earth*, *Mars*, *Jupiter*, and *Saturn*, from the *Sun* to be, as 4. 7. 10. 15. 52. 95. and their Diameters to be, as 3. 5. 8. 3. 52. 44. which yet are Uncertain, Different Aſtronomers giving very Different Calculations of them, *Mercury* in it's Balance wou'd be Equal to *Venus*, if the Bulk of *Mercury* $= 3 \times 3 \times 3 = 27 = A$, $\times 4 = R$ the Diſtance, $\times 1 = C$ the Gravitating or Contractive Force, that is, if $ACR = 108$ is Equal to $5 \times 5 \times 5 = 125 = B$ the Bulk of *Venus*, $\times 7 = r$ the Diſtance, $\times \frac{108}{875} = c$ the Force, that is, if $Bcr = 875 \times \frac{108}{875}$, or, if the Contractive or Gravitating Force of *Mercury* is to that of *Venus*, as 1 to $\frac{1}{8}$, or thereabout; But *Venus* is near Twice the Diſtance from the *Sun*, that *Mercury* is, and ſince the proper Forces are Increas'd, the farther they are Remov'd from the Center of Detention, we muſt take half of the Force in *Venus* for it's proper Contractive one, and therefore the Real Contractive Force in *Mercury*, to that in *Venus*, will be as 16 to 1: And when we conſider the near Approach, which *Mercury* makes to the *Sun*, we need not wonder, that it's Conſtitution has ſo great a Proportion of the Phlegmatick and Contractive in it, ſince otherwiſe, in all Likelihood, it wou'd be Diſſipated into Fumes and Vapours; But theſe Diſtances muſt be Alter'd, if what follows, §. 9. is True.

BY the ſame Way of Reaſoning, the Moment of the *Earth* = to that of *Mercury*, will be, ſuppoſing $z =$ to the Contractive or Gravitating Force of the *Earth*, $5120z = 108$, and the Contractive Force at the *Earth*'s Diſtance from the *Sun* $= z = \frac{108}{5120} = \frac{1}{51}$, or thereabout; therefore, ſince the Diſtance of the *Earth* from the *Sun*, is to that of *Mercury* from the *Sun*, as 10 to 4, or as $2\frac{1}{2}$, or, ſuppoſing, 3 to 1, the proper Contractive Force of the *Earth*, in Compariſon with that of *Mercury*, will be $\frac{1}{3}$ of $\frac{1}{51}$, or $\frac{1}{153}$, or the Contractive Force of *Mercury* will be 153 Times Greater than that of the *Earth*'s.

THUS alſo *Mars*'s Moment will be $= 405z = 108$ the Moment of *Mercury*, and $z = \frac{108}{405} = \frac{1}{4}$, or thereabout, but the Diſtance of *Mars* from the *Sun* is to that of *Mercury* from the *Sun*, as 15 or 16 to 4, or as 4 to 1, the proper Contractive or Gravitating Force, therefore, of *Mars* in Compariſon with that of *Mercury*, will be $\frac{1}{4}$ of $\frac{1}{4}$, or $\frac{1}{16}$, or the Contractive Force of *Mercury* will be 16 Times Greater than that of *Mars*.

LIKEWISE the Moment of *Jupiter* will be $= 7311616z = 108$, the Moment of *Mercury*, and $z = \frac{108}{7311616}$, or $\frac{1}{73116}$, or thereabout; But *Jupiter*'s Diſtance from the *Sun* is to that of *Mercury* from it, as 52 to 4, or 13 to 1, therefore $\frac{1}{13}$ of $\frac{1}{73116}$, is Equal to the proper Gravitating or Contractive Force of *Jupiter* in Compariſon with that of *Mercury*, or the Contractive Force of *Mercury* is to that of *Jupiter*, as 950508 to 1.

LASTLY, The Moment of *Saturn* is Equal to $8292680z = 108$ the Moment of *Mercury*, or $z = \frac{108}{8292680} = \frac{1}{82926}$, or thereabout; But the Diſtance of *Saturn* from the *Sun* is to that of *Mercury* from it, as 95 to 4, or, as 24 to 1 nearly, therefore the proper Force of Gravitation or Contraction of *Saturn* will be, in it's Compariſon with that of *Mercury*, $\frac{1}{24}$ of $\frac{1}{82926}$, or the Contractive or Gravitating Force of *Mercury* will be to that of *Saturn*, as 2090224 to 1. And the ſame Kind of Calculation may be Extended to the *Moon*, and the *Secondary Planets*; which *Calculus* of the Forces of the Planets, I dare Affirm and can Prove, requires no more Precarious Things than what are Demanded by Sir *Iſ. Newton* in his Determining the Denſities of Them.

Sir Iſ. Newt. Princip. Prop. 8. & Corol. Edit. 1. & 2.

Concerning the Periodical Times, and the Diſtances

§. 9. IF therefore *Mercury* by it's Force, according to the Method we have before Explain'd, is capable of Revolving round the *Sun*, all the Planets at their ſeveral Diſtances, and whoſe Moments are ſuppos'd Equal to that of *Mercury*, will admit of

Revo-

of the Planets, and how we may Aſcertain the Latter from the Former.

Revolutions at thoſe Diſtances; *Mercury* Performs it's Period in about 3 Months, *Venus* in $7\frac{1}{2}$, or 8 Months, the *Earth* in 12, *Mars* in 24, *Jupiter* in 144, and *Saturn* in 360. Conſequently, If the Moments of the Planets are Equal, as there is all the Reaſon in the World to think they are, in their Revolutions about the *Sun*, becauſe there can be no Imaginable Account given, why, if *Mercury*, for Inſtance, revolves round it, by a certain Moment made up of it's particular Force, the Quantity of that Force, and the Diſtance, *Venus* ſhou'd not do it by an Equal Moment, made up of it's particular Force, the Quantity of that Force, and it's Diſtance; ſince, whatever the Action is betwixt theſe Bodies and the *Sun*, the Relative Moment, which they have to each other, muſt be the ſame, unleſs we ſuppoſe the *Sun*, or theſe Bodies, can Exert themſelves Differently, all Circumſtances continuing the ſame, or alike and in the ſame Manner, when the Circumſtances of 'em, as thoſe of the Moments of Force, Quantity, and Diſtance, are alter'd; which is as much as to affirm, that the *Sun* can Burn up the *Earth*, at the Diſtance of *Mercury*, and yet be no Hotter than it is with us, at the ſame Diſtance. If then the Moments of the Planets are Equal, and *Mercury* at the Diſtance of 3, and with it's proper Force, and the Bulk or Quantity of it, deſcribes it's Period or Circle, which will likewiſe be as 3, in 3 Months, *Venus* at the Diſtance of $7\frac{1}{2}$ or 8, will perform it's Period, which will be as $7\frac{1}{2}$ or 8, in $7\frac{1}{2}$ or 8 Months, the *Earth* at the Diſtance of 12, it's Period, which will likewiſe be as 12, in 12 Months, *Mars* at the Diſtance of 24, in 24 Months, *Jupiter* at the Diſtance of 144, in 144 Months, *Saturn* at the Diſtance of 360, in 360 Months. But theſe are not the Diſtances Aſſign'd by Aſtronomers, which are of *Mercury*, as 4, which is 1 More than theſe Periods and theſe Equal Moments require, of *Venus*, as $7\frac{1}{2}$ or 8, which is Agreeable and Correſpondent to them, of the *Earth*, as 10, which is 2 Leſs, of *Mars*, as 15, which is 9 Leſs, of *Jupiter*, as 52, which is not half ſo much, of *Saturn*, as 92, which is not one Third ſo much, as theſe Periods and theſe Equal Moments aſſert. Is it therefore Juſt and Reaſonable for us to aſcertain the Diſtances by the Periods, and Equal Moments, or the Periods by the Diſtances? If the Former, we proceed according to Fair and Rational Deductions, if the Latter, we ſtand by very Fallible, and very Uncertain Obſervations.

Dr. Keill's Aſtronom. Lect. 27.

As to the Periodick Times, They are Determin'd, by finding Two Heliocentrick Places of a Superior Planet, from Two Oppoſitions of it with the *Sun*, and of an Inferior, from Two Conjunctions with it, or from it's Greateſt Elongations, for the Arch, betwixt thoſe Places, will be to the Circumference, as the Time, in which it is deſcrib'd, to the Periodick Time; or elſe by the Planet's being Twice in the ſame Node, for the Time betwixt the Two Obſervations is the Periodick Time; ſuppoſing then the Equal Moments of the Planets, if one Planet, with a Certain Moment, deſcribes one Certain Space in one Time, Another, with an an Equal Moment, will deſcribe Twice the Space in Double that Time, and Thrice the Space in Treble the Time, *&c.* and conſequently, ſince the Circles are Proportional to their Radius's, or the Orbits of the Planets to their Diſtances from the *Sun*, the Radius's will be Determin'd from the Circles, or the Diſtances from the Revolutions, but not the Contrary.

The Modern Way of Aſcertaining the Diſtances of the Planets, Precarious and Fallible.

Rohault. Phyſ. Cap. 13. Part 2. Annotat.

Sir Iſ. Newt. Princip. Phænom. 4. Lib. 3.

§. 10. For, on the Contrary, in the firſt Place, the Diſtances in Fact are Variouſly recounted by Aſtronomers, ſome making the *Earth* to be 12000 of it's Diameters Remov'd from the *Sun*, others 10000, and the Lateſt, and, it is ſaid, the moſt Exact, only 5000, and this vaſt and immenſe Difference ariſes from the great Difficulty and Labour of Determining the *Sun*'s Parallax; If therefore the Diſtance of the *Earth* from the *Sun* is thus unſettled, we cannot ſuppoſe that thoſe of the other Planets are much better aſcertain'd. And even thoſe, who pretend to compute them, from the Squares of the Periodick Times being as the Cubes of the Diſtances, which Diſtances yet are thus Precarious, make them Differ from what is ſaid to be found by Obſervation.

The Middle Diſtances of the Planets and the *Earth* from the *Sun*,

	Saturn.	*Jupiter.*	*Mars.*	The *Earth.*	*Venus.*	*Mercury.*
According to *Kepler*,	951000.	519650.	152350.	100000.	72400.	38806.
Bullialdus,	954198.	522520.	152350.	100000.	72398.	38585.
The Periodick Times,	953806.	520116.	152399.	100000.	72333.	38710.

IN which the Diſtances, Calculated from the Periodick Times, are Different, from what are affirm'd by Aſtronomers, ſeveral Hundred Parts, and ſometimes more than a Thouſand, each of which Parts is one Hundred Thouſandth Part of the *Earth's* Diſtance from the *Sun*, which, according to the moſt moderate Computation, will be 54 Millions of Miles, and therefore one of thoſe Parts will be Equal to 540 Miles, and a Thouſand of them to 540 Thouſand Miles, which is above Twice as far, as the Moon is from us, and therefore no Minutia in Nature.

BESIDES which, let us now Examine into the Way and Method, by which theſe Diſtances are Computed, which is, by firſt finding the Parallax of the Phænomenon or Planet, whoſe Diſtance is Requir'd, and then it will be, as the Sine of the Parallax, to the Sine of the Apparent Diſtance of the Phænomenon or Planet from the Vertex, ſo the Semidiameter of the Earth, to the Diſtance of the Phænomenon or Planet from the Earth's Center. But this Obſervation of the Parallax is acknowledg'd to be a very ſlippery and uncertain one, and the Propoſitions, which are afterwards made uſe of, to make it leſs liable to Error, depend upon the Theory of the Planets before deliver'd and the Ratio of their Diſtances to one another, whereas their Diſtances, and their Ratio to one another are firſt to be determin'd by Previous Obſervations, and from thence the Theory of the Planets is to be form'd and deriv'd, and not aſſum'd to aſcertain the Parallax, and from it the Diſtances. In the foregoing Proportion therefore, there are Two Things, which render the Diſtance very Precarious, which is Concluded from it, Firſt the Semidiameter of the *Earth*, and Second the Parallax.

Dr. Gregory's Aſtronom. Prop. 46. Lib. 2.

Dr. Keill's Aſtronom. Lect. 22.

Dr. Gregory's Aſtron. Sect. 6. Prop. 43, 44. Lib. 3.

As to the Firſt, ſome make the whole Diameter to contain 8202 Miles, and others only 7935, in which there is a Difference of above 200 Miles; but that which Contributes the moſt to this Uncertainty, is the Parallax, where the Angles are ſo Minute, that the leaſt Error in Obſervation, which is eaſily committed, will occaſion a great Diſproportion in the Diſtances aſſerted from them. And this is ſo entirely own'd, in Reſpect of the fixt Stars, that it is thought their Diſtances can be no ways determin'd, for if the Parallax of the Orbis Magnus, which, according to Mr. *Flamſteed*, is 42″, ſhou'd be 25″ more than it Really is, which is an Error, in taking ſuch ſmall Angles, which can ſcarcely be avoided, the Diſtance of the fixt Stars wou'd be Double of what is affirm'd from Obſervation. And in the Planets, if any Phænomenon is farther Diſtant than 15000 Semidiameters of the Earth from it's Center, which the Sun is ſaid to be, even it's Horizontal Parallax becomes Inſenſible.

Dr. Keill's Aſtronom. Lect. 8. & 22.

THUS alſo it is aſſerted, that, in each of the Superior Planets, *Mars*, *Jupiter*, and *Saturn*, the Parallax of the Orbis Magnus is as the Angle, under which the Semidiameter of that Orb, paſſing thro' the Earth, is ſeen from the Planet, and by how much Nearer the Planet is to the *Earth*, and to the *Sun*, by ſo much will that Angle be Greater, the Parallax therefore of the Orbis Magnus being given in every Planet, it's Diſtance from the *Sun*, it is ſaid, will be Determin'd, in Reſpect of the Earth's Diſtance from it; For the Elongation of the Planet from the *Sun* is known by Obſervation, or by a Calculus, And, as the Sine of the Parallax of the Orbis Magnus, is to the Sine of the Elongation of the Planet from the *Sun*, ſo is the Diſtance of the *Earth* from the *Sun* to that of the Planet from it.

Dr. Keill's Aſtronom. Lect. 16. p. 217.

BUT here again are the Two Recurring Difficulties, how the Parallax of the Orbis Magnus from each Planet, and the Diſtance of the *Earth* from the *Sun*, ſhall be accurately and ſufficiently defin'd, the laſt as we have ſhewn is not done, becauſe the Parallax of the *Sun* cannot be, *Jupiter* and *Saturn* are ſtill farther Diſtant from it, and therefore their Parallaxes will be more Minute, *Venus* is the neareſt to it, and therefore it's Parallax the moſt ſenſible and the beſt determin'd, and conſequently we find §. 9. it's Diſtance, and it's Periodick Time to Agree, and that of the *Earth* and *Mercury* not much to Differ, *Mars* ſomething more, and *Jupiter* and *Saturn* the moſt of all. Beſides one Fundamental Maxim in this Reaſoning about the Diſtances of the Planets is, that the Apparent Diameters of them are increas'd in Proportion to their Approximation to us, which is falſe by what we Experience in other Objects, and is unprov'd in Theſe; Alſo the Heights of any Phænomenons are ſo hard to be determin'd, that I have known very good Obſervers miſtake One or Two Yards in Fifty, which will be no Wonder to thoſe who underſtand, how Nice and Critical Trigonometry is in the Practice, and conſequently the Error in the Meaſure of many Millions of Millions cannot be Inconſiderable.

Dr. Keill's Aſtronom. Lect. 1. & 27. P. 440.

WHAT therefore we wou'd Infer from hence is, that ſince it is ſo difficult a Matter to fix the Diſtances of the Planets from the Parallaxes, and the Obſervations of them, and ſince, where the Parallaxes are the moſt ſenſible, the Periodick Times come the neareſt to a Proportion with their Diſtances, we may juſtly attribute their Receding from that Proportion to the fallibleneſs and uncertainty of Obſervations, and may therefore Conclude, that the Squares of the Periodick Times are not as the Cubes of the Diſtances, or, which is the ſame, that the Periodick Times are not as the Square-Roots of thoſe Cubes, or in a Seſquiplicate Proportion, but as the Cube-Roots of thoſe Cubes, that is, as their Diſtances.

Concluſions from the foregoing Doctrine.

§. 11. IF this is ſo, which I ~~only~~ Propoſe, and leave to the Inquiries of Others, the Moments of the Planets, with reſpect to the *Sun*, will be the ſame, and their Forces ſuch as I have before mention'd, §. 8. and it will be from thence moreover Conſequent.

1. THAT the Nearer or Farther any Planet is from the *Sun*, it's proper Contractive or Gravitating Force will be Greater or Leſs, excepting in *Mars* and *Venus*, which have the ſame, and are compenſated by the greater Bulk or Quantity of the one near the *Sun*, as in *Venus*, and by the Leſs in the other, which is more Remote from it, as in *Mars*.

2. THAT the Matter therefore in *Mercury* is very near, as Intrinſically Different from that of *Venus* or *Mars*, as Gold with us is from Water, and that it is very near ſo much Heavier and Denſer; that the Matter of *Mercury*, in Reſpect of that of the *Earth*, is 8 Times Heavier and Denſer than Gold is in Reſpect of Water with us, *&c.*

3. THAT the Matter of *Jupiter* is above 6000, and that of *Saturn* above 10000 Times leſs Denſe and Heavy than that of the *Earth*'s, which will not therefore, according to the Notions of the preſent Philoſophy of Similar Matter, be Infinitely Porous, but will be of a Thinner and more Diluted Nature, will fill the ſame Dimenſional Spaces, but the Forces will be Different, leſs Contractive, and more eaſily excited into Action by the *Sun*'s Rays, ſo that the Nature of it may be as juſtly proportion'd to all the Influences of the *Sun* at that Diſtance, as that of the *Earth* is to them at it's Diſtance, or *Mercury* in it's particular Proximity to it. If any one objects other Calculations of the Denſities of the Planets, or the Proportions of them, they proceed upon a Suppoſition of Matter's being Homogeneous and Similar, which we here again Deny, as having been already Confuted.

Sir Iſ. Newt. Princip. Prop. 8. Lib. 3. Theorem 8.

4. THAT hence it is Manifeſt, how Different Matters, and their having in themſelves Different Forces and Moments, may at various Diſtances proceed in an Equable Motion; If the Matter of *Saturn* was the ſame, as that of *Mercury*, at ſuch an Immenſe Diſtance from the *Sun* it's Center of Detention, it wou'd be carry'd with an infinitely Greater Velocity, but it's Force being leſs, and it's Diſtance greater, and the Quantity of thoſe Forces greater, ſo as to be in an Equal Moment with *Mercury*, it will deſcribe the ſame Space in the ſame Time, and therefore it's Periodick Time will be in a Proportion to it's Diſtance; the Preſent Aſtronomers ſay, that it is in the Ratio of the Square of the Time to the Cube of the Diſtance, or as the Periodick Time to the Square-Root of that Cube, which, if we will allow for the uncertainties of Obſervation, may poſſibly be reduc'd to the Cube-Root of that Cube, or the Periodick Time will be as the Diſtance, which we here Account for, but how it ſhou'd be ſo nearly in that Proportion, as the Square-Root of the Cube, is not in the leaſt Explain'd by the Phyſical Aſtronomy, and by that Similar and Homogeneous Matter, which it has thought fit to adopt.

Theorem the Second explain'd.

§. 12. THEOREM the Second is, That the Sums or Quantities of the Contractive or Gravitating Forces are in a Reaſon compounded of a Direct one of the Moments, and of a Reciprocal of the Forces, the Percuſſions, and the Removals from the Center of Detention; For, by the Preceding Theorem, $\frac{M}{m} = \frac{ACPR}{Bcpr}$, therefore $\frac{A}{B} = \frac{Mcpr}{mCPR}$.

§. 13. **Theorem** the Third is, That the Contractive or Gravitating Forces are in a Reaſon compounded of a Direct one of the Moments, and of a Reciprocal of the Sums or Quantities of the Forces, of the Percuſſions, and the Removals from the Center of Detention; For, by the Firſt Theorem, $\frac{M}{m} = \frac{ACPR}{Bcpr}$, therefore $\frac{C}{c} = \frac{MBpr}{mAPR}$.

Theorem the Third explain'd.

§. 14. **Theorem** the Fourth is, That the Percuſſions are in a Reaſon compounded of a Direct one of the Moments, and of a Reciprocal of the Forces, the Quantities of the Forces, and the Removals from the Center of Detention; For, by the Firſt Theorem, $\frac{M}{m} = \frac{ACPR}{Bcpr}$, therefore $\frac{P}{p} = \frac{MBcr}{mACR}$.

Theorem the Fourth explain'd.

§. 15. **Theorem** the Fifth is, That the Removals from the Center of Detention are in a Reaſon compounded of a Direct one of the Moments, and of a Reciprocal of the Forces, the Quantities or Sums of the Forces, and of the Percuſſions; For, by the Firſt Theorem, $\frac{M}{m} = \frac{ACPR}{Bcpr}$, therefore $\frac{R}{r} = \frac{MBcp}{mACP}$.

Theorem the Fifth explain'd.

§. 16. **Theorem** the Sixth is, That the Spaces perform'd by Bodies, which obtain a Contractive or Gravitating Force, and a Force of Percuſſion, and which Act round a Center of Detention, are in a Direct Reaſon of the Forces, the Percuſſions, and their Diſtances from the Center of Detention, where ſuch Forces and Percuſſions act in Conjunction, and ſpend their Moment forwards, and do not return back in Oſcillations, as alſo of the Times and the Denſities of the Spaces perform'd, That is, $\frac{S}{s} = \frac{CPRTD}{cprtd}$. Thus ſuppoſing a Point at *G*, Fig. preced. has a certain Force of Percuſſion and Gravitation, by which at the Diſtance *CG*, it wou'd be carry'd round it's Orbit in a Day's Time, a Gravitation and Percuſſion of a Hundred Times the Force at *G* wou'd deſcribe a Space a Hundred Times Greater, that is, an Orbit whoſe Semidiameter wou'd be a Hundred Times Longer than *CG*; and if the Diſtance *CA* is a Hundred Times Greater than that of *CG*, the Force at *A* wou'd be ſo much Increas'd, and conſequently by that Means wou'd deſcribe 100 of thoſe Spaces, or Orbits, in a Day's Time, and in 100 Days 10000 of them; and ſuppoſing the Spaces, thro' which theſe Revolutions are made, are a Hundred Times Denſer than the others, they will be Equal to 1000000 of the former Revolutions in which the Spaces were a Hundred Times Thinner and more Diluted. Where we ſpeak of the Denſities of Spaces, we do not conſider the Reſiſtances or Actions of them, but only their Cloſer or more Conſtipated Space and Extenſion; If therefore likewiſe the Actions of theſe Spaces were Included in the preſent or former Reaſoning about Space, there wou'd ſtill other Proportions ariſe to the Moments of Bodies, Moving in Them, than what we have mention'd. We ſhall not at Preſent conſider, what Effect Different Percuſſions wou'd have, for the Reaſons alledg'd above, nor yet, what wou'd be the Caſe of differing Denſities, which, with their proper Forces and Actions, yet, in Real Space, and not an Abſtracted and Imaginary one, we may juſtly think will obtain ſome Moment in the Motions of Bodies, and even in the Revolutions of the Planets.

Theorem the Sixth explain'd with it's Corollaries. That the Spaces perform'd by Contractive Bodies Revolving round a Center of Detention are in a Direct Reaſon of the Contractive Forces, the Percuſſions, the Diſtances from the Center, as alſo of the Times and the Denſities of the Spaces.

Corol. 1. If therefore $P = p$, and $D = d$, $\frac{S}{s} = \frac{CRT}{crt}$, That is, one Space, which is perform'd, will be Greater than another, in Proportion, as the Gravitating or Contractive Force, the Removal from the Center of Detention, and the Time is Greater, in which the Greater Force Acts.

Corol. 2. If now $C = c$, $\frac{S}{s} = \frac{RT}{rt}$, or the Spaces perform'd will be Greater, if the Forces are Equal, as the Diſtances from the Center, and the Times, in which Equal Forces Act, are Greater.

Corol. 3. If $R=r$, $\frac{S}{s}=\frac{CT}{ct}$, or, if the Diſtances from the Center are Equal, the Spaces perform'd will be Greater, as the Forces, and the Times, in which Greater Forces Act, are Greater.

Corol. 4. If $T=t$, $\frac{S}{s}=\frac{CR}{cr}$, or, if the Times, in which the Forces Act, are Equal, the Spaces perform'd are Greater, as the Forces and the Diſtances from the Center of Detention are Greater.

Corol. 5. If $C=c$, and $R=r$, or $CR=cr$, $\frac{S}{s}=\frac{T}{t}$, or, if the Forces and Diſtances from the Center, or the Moments of them together, are Equal, the Spaces perform'd will be as the Times, in which thoſe Equal Forces Act.

Corol. 6. If $C=c$, and $T=t$, $\frac{S}{s}=\frac{R}{r}$, or, if the Forces and Times are Equal, the Spaces perform'd will be as the Diſtances from the Center, ſince therefore, where the Forces or Moments of them computed with their Diſtances are Equal, the Spaces, which they deſcribe, will be as the Times, by *Corol.* 5. in ſuch a Caſe $\frac{T}{t}=\frac{R}{r}$, or the Periodick Times will be as the Diſtances; and conſequently, we may juſtly conclude, that this is the Circumſtance of the Heavenly Bodies, ſince that of their Periodick Times being in a Seſquiplicate Reaſon of their Diſtances is not juſtify'd by any Laws of Mechanicks, as we ſhall afterwards ſhew.

Corol. 7. If $R=r$, and $T=t$, $\frac{S}{s}=\frac{C}{c}$, or, if the Diſtances from the Center, and the Times are Equal, the Spaces perform'd will be as the Forces.

Corol. 8. If $S=s$, $CRT=crt$, and $C.c::rt.RT$, or $R.r::ct.CT$, *&c.* for we ſhall go no farther, ſince the Remaining Corollaries may be eaſily deriv'd from the preſent Equation.

Theorem the Seventh explain'd.

§. 17. Theorem the Seventh is, If $\frac{S}{s}=\frac{CRTD}{crtd}$, $\frac{C}{c}=\frac{Srtd}{sRTD}$, $\frac{R}{r}=\frac{Sctd}{sCTD}$, $\frac{T}{t}=\frac{Scrd}{sCRD}$, and $\frac{D}{d}=\frac{Scrt}{sCRT}$, on which we ſhall not Enlarge, but go on to the Expanſive.

Concerning the Expanſive Forces, and their Compariſon with the Contractive.

§. 18. We ſhall now proceed to a Conſideration of the Expanſive Force, and the Theorems which reſult from it, and tho' we made Percuſſion, as well as the Contractive or Gravitating Force to be an Expanſive in Reſpect of the Center of Detention *C*, Fig. preced. becauſe it endeavour'd to recede from it, yet the proper Expanſive Force is that which acts directly Contrary to the Contractive, ſo that as the Contractive, if plac'd in the Center of Detention *C*, wou'd ſtrongly unite it ſelf to it, and preſs towards it, and the farther it retir'd from it the more Languidly and Faintly, or, which is the ſame, more Vigorouſly recede from it; On the Contrary, the Expanſive in the Point *C* will act the moſt forcibly to the Diſſipation of the Contractive, or, any other Force of Detention, which obſtructs it's Action, and more Languidly and Faintly the farther ſuch Force is from the Center of it's Action, or, which is the ſame, leſs violently recede from it. And as to the Laws of the Former or Contractive Force, all Gravitating and Heavy Bodies, ſo far as they are ſo, Cold, Poſitive Reſt, Attraction, Chryſtalization, Coagulation, are to be reduc'd, ſo Fire and Flame, Heat, Vegetation, Fluidity, and Softneſs, Taſt, Smell, and Sound, Light and Colours, Motion, Elaſticity, Ebullition upon the Mixture of an *Acid* and *Alkali*, as they are term'd, will naturally fall under the Laws of the Latter or the Expanſive, as alſo all Animal Force and Action, tho' in all theſe there is a Mixture in Different Proportions of both theſe Forces. The Two Great Principles therefore, which we take to be in Nature, ſo far as it is Material, are thoſe of the Expanſive and Contractive Forces, which Act directly oppoſite to one another, and which are the moſt fully exerted in the utmoſt Heat or Fire, as that of the Sun, and in the utmoſt Cold, as Froſt, and Gravitation it ſelf is no other than a Mixture of the Contractive and Expanſive, in which the Contractive prevails; but ſince we have no exact Meaſures of theſe Forces, we have hitherto made uſe of Heavy Bodies to explain in ſome Degree the Contractive Force from a Center of Detention, and as for the Expanſive, it do's not ſeem to be capable of being reduc'd to any, for there is no Balance of Fire and Flame; we ſhall therefore omit any farther Proſecution of the Centers of Detention and proceed to the Centers of Expanſion and Contraction.

§. 19. **Theorem** the Eighth is, That the Moments of Bodies, which have a Force of Expanſion, and which Act from a Center of it, are in a Reaſon compounded of a Direct of the Expanſive Forces, of the Sums or Quantities of them, and of a Reciprocal of the Diſtances; And if we ſuppoſe a Force acting towards a Center, as the Contractive, and not from a Center of Detention, as before, The Moments of Bodies, which have a Force of Contraction, and which Act towards a Center of it, will be in a Reaſon compounded after the ſame Manner.

Theorem the Eighth explain'd with it's Corollaries; That the Moments of Bodies which have a Force of Expanſion or Contraction, and Act from a Center of it, are in a Reaſon compounded of a Direct one of the Forces, the Sums or Quantities of them, and of a Reciprocal of the Diſtances.

Let us therefore put F, f for the Expanſive or Contractive Forces, and the Moments of Bodies, thus Acting, will be $\frac{M}{m} = \frac{AFr}{BfR}$, That is, the Forces will be Greater as they are Intrinſically ſo, as the Quantities or Sums of them are Greater, and as the Diſtances of their Actions from the Center of them are Leſs; Thus we find it in Fire and Heat, in the Action of the Sun, Percuſſion, Vegetation, and other Expanſive Forces; Thus in Gravitation and Attraction, in Froſt and Cold, which are weaken'd the farther they are from the Center of Contraction, and in other the Contractive Forces.

Corol. 1. If $A = B$, $M . m :: Fr . fR$. *Corol.* 2. If $F = f$, $M . m :: Ar . BR$.
Corol. 3. If $R = r$, $M . m :: AF . Bf$. *Corol.* 4. If $A = B$, and $F = f$, $M . m :: r . R$.
Corol. 5. If $A = B$, and $R = r$, $M . m :: F . f$. *Corol.* 6. If $F = f$, and $R = r$, $M . m :: A . B$.
Corol. 7. If $M = m$, $AFr = BfR$, and $A . B :: fR . Fr$, or $F . f :: BR . Ar$, or $R . r :: AF . Bf$. *Corol.* 8. If $M = m$, and $A = B$, $F . f :: R . r$.
Corol. 9. If $M = m$, and $F = f$, $A . B :: R . r$. *Cor.* 10. If $M = m$, and $R = r$, $A . B :: f . F$.
Corol. 11. $A . B :: MfR . mFr$, and $F . f :: MBR . mAr$, and $r . R :: MBf . mAF$, or $R . r :: mAF . MBf$, &c.

§. 20. We ſhall Firſt therefore conſider the Proportions of Expanſion, the Quantities and Diſtances of it aſſerted in this Theorem, from whence all the Corollaries, which follow it, are deriv'd, and afterwards thoſe of Contraction. Thus in Reſpect of Expanſion it is affirm'd, that it's Force is Greater, as it is Intrinſically ſo, as it's Quantity is Greater, and as it's Diſtance is Leſs.

Inſtances in Nature of the Expanſive Forces.

In Reſpect of the Intrinſick Forces of Expanſion, there is no one will deny, but that the Intrinſick Force of the Flame of Wine, when Burnt, or any other Spirituous Liquor, is leſs in it's Force, than that of the Flame of a Lamp, or a Candle, or any other Oleous Body; that the Flame of an Oleous Body is leſs in it's Force, than that of Common Fire, where a Groſſer Matter is Inflam'd; that Common Fire is ſtill leſs in it's Force, than that of the Immenſe Heat and Fire of the Sun; all Operations in Chymiſtry, where Flame or Ebullitions are produc'd, come under this Head of Expanſive Forces. In Reſpect of the Quantities of theſe Forces, every one knows, that a Spark of the ſame kind of Fire or Flame is leſs in it's Force than a whole Maſs of it, and that one Ray of the Sun is of leſs Power than a Thouſand, or a Million of them Collected together. In Reſpect of the Diſtances, it is alſo Notorious, that the nearer an Approach is made to a Flame, to a Fire, or the Sun, the more violent the Action is, and the more ſenſible is the Heat, and the Expanſive Force of it; and if the *Earth* was plac'd at the Diſtance of *Mercury*, it wou'd in all Probability repel it to the Station, in which it now is, in which it exerts a Gentler and more Moderate Action upon it, to Warm it only into Vegetation, and to keep it in it's Period; and if *Mercury* was where the *Earth* is, it wou'd ſink to it's own Station by the Exceſs of it's Contractive, above the Expanſive of the Sun, and ſo of the other Planets.

Inſtance 1. *The Intrinſick Force of Fire and Flame.*

The Quantity.

The Diſtance.

Thus alſo in Animal Action, as That which exerts it ſelf in the Force of Percuſſion, the Stronger that Action is, the Greater the Quantity of the ſame Force of Percuſſion is, and the Nearer it is to the Center of Percuſſion, that is to the Point, where

Inſtance 2. *The Intrinſick Force of Animal Action, as Percuſſion. The Quantity. The Diſtance.*

where the Stroke is made, upon all theſe Accounts, the Expanſive Force will be Increas'd, and upon the Contrary Diminiſh'd.

Inſtance 3. Vegetation.
The Intrinſick Force.
The Quantity.
The Diſtance.

LIKEWISE in Vegetation, in which there is a Principle of Expanſion contrary to that of Contraction or Gravitation, by which the Stronger it is in it ſelf, and the Greater Quantity there is of the ſame Force, and the Nearer it is to the Center of it's Exertion, the more Power and Moment it will have. For there is more Expanſive Force in one Plant, than there is in Another, as one Riſes higher than another, and this is but a weak Expanſion, and a ſmall Degree of it in all of them; The Force or Principle of Expanſion is ſtill Greater in Shrubs, and the Greateſt in Trees, ſuppoſing the Contractive Force is Equal. And as the Quantities or Sums of theſe Forces are Increas'd, the Moment of them is Greater, thus the Moment of the Expanſive Force in an Oak, is Greater than that in a Walnut or a Willow, in a Walnut or a Willow, than in a Thorn or a Haſle, and in them, than in Plants and in Moſſes; and in the ſame Tree it is Greater in the Root and Trunk, than in the Shoots of the Root or in the Branches, Greater in the Shoots, than in the Strings and Fibres of them, and Greater in the Branches than in the Leaves. Thus alſo the Expanſive Force in Vegetation is Greater in leſs Diſtances from the Center of it's Action, and Leſs in greater Diſtances from it, from whence it is, that in the Root or Center, where this Expanſive Force is the Greateſt, the Colour is ſometimes Rediſh, or a Kind of Orange, or Yellow, or a Yellowiſh White, whereas in the Foliage, or in the Extremities, or greateſt Diſtances of it's Action from the Center, the Colour is generally Green; but, from what we have ſaid in the Doctrine of Light and Colours, Red, Orange, and Yellow are produc'd in us by the Stronger Actions of the Sun's Rays, and Green by the Weaker, Suitably theſe Expanſive Forces, ſtrikeing upon the Ethereal Plenum, with a Greater Percuſſion in the firſt Caſe, give us the Senſations of Red, or Orange, or Yellowiſh, or Pale Yellow, and in the laſt with a Weaker, the Senſations of Various Greens; and the Colours of Flowers proceed from Different Proportions of the ſame Expanſive: Fluidity, and Softneſs, and Taſt and ſome other Qualities in Bodies have a Degree of Expanſion, but we ſhall not conſider them here, becauſe the Inſtances we ſhall at Preſent make uſe of, ſhall be only of thoſe Expanſive Forces, which diſplay themſelves the moſt ſenſibly, that we may thereby the better judge of the Nature and Manner of their Action.

Inſtance 4. Odorous Bodies.
The Intrinſick Force.
The Quantity.
The Diſtance.

SMELL is the next we ſhall Select, which is accounted for, by ſuppoſing, that ſeveral Effluviums are ſent out from the Odorous Body to a certain determin'd Sphere round it, which yet ſeems to be nothing more than this Expanſive Force, Acting upon the Ethereal Plenum, which environs it, to a certain Diſtance; And the Odour is Stronger, as the Expanſive Force is Greater, or as the Quantity of it is Greater, and the Diſtance from the Center of it's Action is Leſs.

Inſtance 5. Sound.
The Intrinſick Force.
The Quantity.
The Diſtance.

ANOTHER Expanſive Force we ſhall mention is, that of Sound, which is Greater, as the Expanſive Force is Greater, as the Quantity of it is ſo, and as the Diſtance is Leſs; a quicker and a more lively Expanſion ſtrikes upon the Ethereal Plenum, and conſequently, the Ear with a ſtronger Percuſſion, all other Things being Equal, than a Flatter, and a Duller, and a Shrill Sound pierces more than a Grave or an Hoarſe one. A Greater Quantity of this Force adds likewiſe to the Moment of it, and a Shrill Bell will make a Greater Impreſſion upon us, than the String of a like Note in a Harp, or a Violin, and a Larger Bell than a Smaller. A leſs Diſtance alſo from the Sonorous Body Increaſes the Sound, and a farther Removal from it Diminiſhes it.

Inſtance 6. Colour.
The Intrinſick Forces.
The Quantity.

THE Sixth kind of Expanſive Force we ſhall Name, ſhall be that of Colour, which by what we have ſhewn in our Philoſophy of Light and Colours, conſiſts of Different Intrinſick and Expanſive Forces, Red has the greateſt, Orange the next, Yellow is after Orange, Green, Blue, and Violet ſucceed the Yellow, and deep Violet has the leaſt Expanſive Force of all, in the Sun's Rays tranſmitted and alter'd thro' a Priſm. And the ſame we may aſſert in Reſpect of Colour'd Bodies, ſtrikeing upon the Ethereal Plenum, with their particular and diſtinct Forces of Expanſion, that Red Bodies have the greateſt Force of Expanſion, Orange the next, and ſo Yellow, Green, Blue, and Violet, and deep Violet in order have a Weaker. And all theſe Differing Colours are more eaſily ſeen, the Larger and Greater the Quantity is of them, a colour'd Point is not ſo readily diſtinguiſh't, as a colour'd Body, the Mind is more

Dubious to what Colour to aſſign a ſmall Atom of Matter, than a whole Maſs of it, and ſtill the Larger that Maſs is, and the Greater the Uniformity of the Impreſſion upon the Senſes, the Mind is left leſs to doubt of the Certainty of the Colour exhibited to it; This perhaps may not be ſo fully apprehended, unleſs after a juſt and perfect Conſideration of it. We may farther ſay, that the Nearer we approach to any colour'd Body, the more Fully and Diſtinctly we perceive it's Colour, and the Farther we are remov'd from it, it is more confuſed and undetermin'd, and therefore it's Expanſive Force Weaker.

The Diſtance.

The Seventh Sort of Expanſive Force we ſhall conſider, is that of Motion, which is the Second Inſtance of the Expanſive Force in Animal Action, Thus it is maniſeſt, we can ſtrike or throw a Ball with a Greater or Leſs Force, and the Moment of it will accordingly be ſo. If we uſe a Finger to communicate this Expanſive Force, it will be Leſs, if a Hand, Greater, and if we exert the whole Moment of all the Muſcles ſubſervient to that End, it will be the Greateſt of all, that is, if the Quantity of the Expanſive Force is the Greateſt. And ſuch a Motion Communicated will be diminiſh'd (as all other Forces are) the Farther it is from the Center of it's Action.

Inſtance 7. Motion impreſs'd.
The Intrinſick Force.
The Quantity.
The Diſtance.

Another Force of Expanſion is that of Elaſticity, which has been ſufficiently exemplify'd in that of Sonorous Bodies.

Inſtance 8.

The laſt Inſtance, we ſhall make uſe of, is that Expanſive Force, which is obſervable in Animal Bodies, which is the Third Inſtance in Animal Action, The Expanſive Force is Greater in the Animal Syſtem of an Eſtrich or an Elephant, than that of an Inſect or a Fly, in a Greater Brute, than in a Leſſer, in a Man, than in a Child, and in one of a Greater, than in one of a Leſſer Stature, all other Things being Equal. The Quantity of the Intrinſick Forces may be exemplify'd the ſame way, for in the foregoing Inſtances, as the Intrinſick Forces are Greater in the one than the other, ſo are likewiſe the Quantities of them. And in all theſe Caſes, the Expanſive Forces are the ſtrongeſt at the Centers, and the weakeſt at the Extremities of the Syſtems, there is more Expanſive Force in the Heart, than there is in the Finger, more in the Blood than in the Veſſels, which contain it, more in the Muſcles, than there is in the Skin, but to fix the preciſe Center of this Expanſive Force, will perhaps be difficult to do, and if we take the Heart, it may be as Probable a one, as any other Point in the Animal Frame, but that we ſhall not now Determine, having given Inſtances enough of the Expanſive Force to the purpoſe of the preſent Theorem, and when we come to our Inquiry into the Principles of Anatomy, we ſhall more fully Explain our ſelves upon that Subject.

Inſtance 9. The Animal Syſtem.
The Intrinſick Force.
The Quantity.
The Diſtance.

§. 21. The Expanſive Force we make to be that, which retires by it's own Energy from a Center, and which therefore is adapted to the Diſpelling and Diſcuſſing of Bodies, which lye in it's Way, on the other Hand the Contractive Force Tends and Acts towards a Center, and therefore Cements, Unites, and Precipitates them to each other, of which laſt Force we ſhall give the following Inſtances.

Inſtances in Nature of the Contractive Forces.

The Contractive Force of Common Salt imparts a Coldneſs to Water, which has ſome Degree of the Expanſive in it from it's Fluidity, and it is known to have this Effect, *viz.* to Cement a Pewter Veſſel, in which the Salt and Water is contain'd, to a Piece of Wood, on which it ſtands;

Inſtance 1. Cold.
The Intrinſick Forces.

The Salts, which mix with the Aqueous Particles in the Air, are ſtill ſtronger by Cementing the Particles of Water it ſelf into Snow and Hail; the Salts, which are infus'd into Water in Froſt, obtain a Greater Force, by which they change it into a Solid and Conſiſtent Body, Ice;

Inſtance 2. Salts.

The Stupendous Globe of Solid and Compacted Salt, the Moon, is yet ſtronger in it's Efficacy and Force, and has it's Influences at 60 Semidiameters of the Earth, or about 240000 Miles from us, ſo that as the Different Kinds of Fire and Flame amongſt us, are deriv'd from that Immenſe Source of it, the Sun, by it's Actions upon our Planet, we may with the ſame and equal Juſtice think, that all Cold and the Various Salts, which are Productive of it, are deriv'd from the Moon, and which therefore is plac'd by the Infinite Wiſdom of Almighty God, at that Diſtance from the Earth, both to Reflect Light to us, and to be a Principle of the Contractive Force, as the Sun is of the Expanſive, which are ſo Evident and Manifeſt in all the Beings we converſe with: That the Moon has this Influence of Cold, is as Evident, as the Sun has that of Heat, ſince in Winter, when the Sun has the leaſt Power by

Inſtance 3. The Moon which ſeems to be an Immenſe Globe of Rock-Salt or Metallick Ice, the Reaſons.

From hence in Winter Clear Moon-ſhine Nights the Froſtieſt.

it's Expanſive Force to Obſtruct the Contractive of the Moon, and when the Air is clear from Vapours, and the Moon obtains it's full Contractive Force, the Nights are always the Sharpeſt and the Froſtieſt, and it has the very ſame Effect in Reſpect of Cold, as the Sun has in Reſpect of Heat, if we compare the Circumſtances of the one with the other; And all Nights are more Cold, when the Moon, as all Days more Hot, when the Sun Prevails.

From hence the Exceſſive Cold in the Northern Climates.

WHAT farther confirms this Aſſertion is, that the nearer we approach to the Northern Pole, and the leſs Effect the Expanſive Force of the Sun has, and the Greater the Contractive of the Moon, the Colder thoſe Parts are, being oppreſs'd with a continual Froſt and Snow, which cannot proceed from any Different Intrinſick Force of the Earth it ſelf, and therefore muſt be owing to a Foreign Impreſſion.

From hence the Higheſt Mountains, and the Higheſt Parts of the Atmoſphere are the Coldeſt.

IT may be alſo alledg'd in Reſpect of the Higheſt Mountains, and the Higheſt Parts of the Atmoſpere, all other Things being Equal, that the Higher they are, the Colder they are, which can be attributed to nothing elſe than their nearer Approximation to the Moon, which will have a much Greater Influence upon them, by ſuch an Elevation than the Sun can have, becauſe the Sun is, at the leaſt Computation, 54 Millions of Miles from us, whereas the Moon's Diſtance is only 240 Thouſand at the moſt, a ſmall Approximation therefore towards the Moon, will have a conſiderable Effect in Compariſon with that towards the Sun, which will have Little or None at all.

From hence the Pale and Silver Light of the Moon deriv'd.

A farther Argument, which we have for the Truth of this, is, That, in fact, Salts Reflect Light with a Greater Force than Earth do's, and which therefore we may ſuppoſe to be the Caſe of the Moon, which, as all other Contractive Bodies, has a contrary Action to the Expanſive of the Sun, and therefore will more Vigorouſly repel it; Salts do likewiſe reflect a Pale and Silver Light, which is the known Property of this Luminary; Nothing of which ſo fully Agrees with a Reflection of it from an Earthy or Graſſy Surface.

From hence the Rays Reflected from the Moon not capable of being Collected to a Burning Focus.

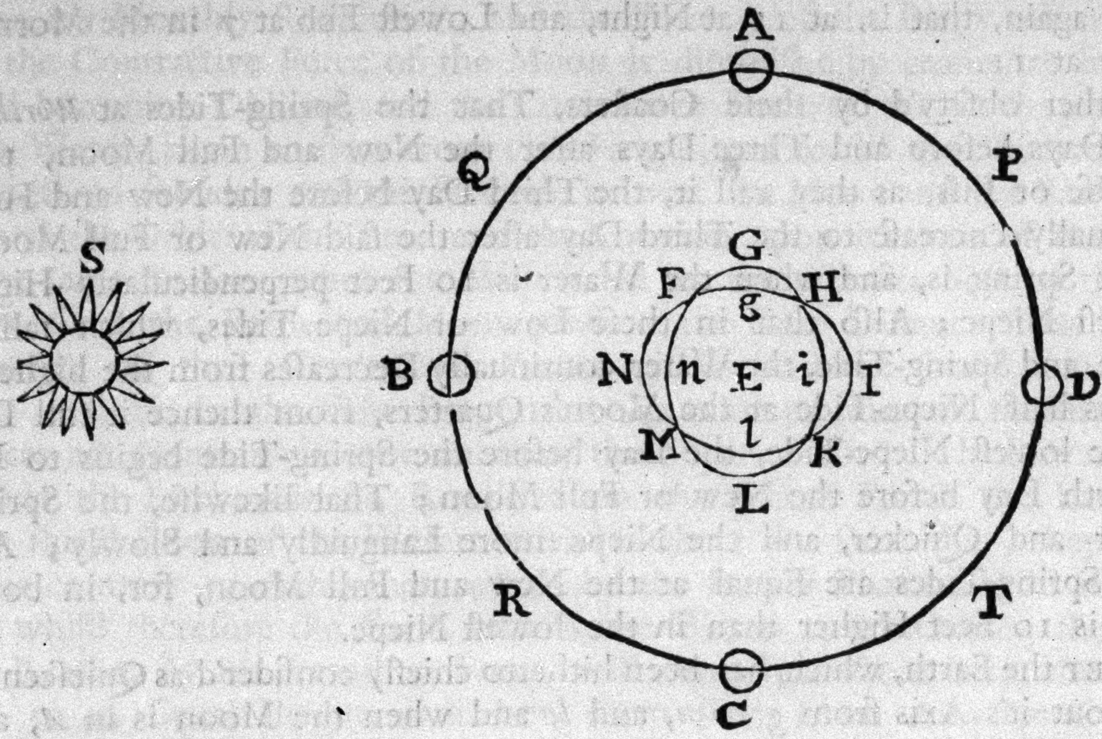
AND laſtly, in the Old or New Moon immediately before or preſently after it's Conjunction with the Sun, the Solar Rays which are reflected from it, are not much diverted from a Rectilinear Progreſs to the Earth, and yet are ſo far from having the Heat and Warmth of the Direct ones, that they can by no Means, nor by any Glaſſes be Collected to an Inflammatory Focus, which can ariſe from nothing elſe, but from the Impreſſions of Cold, which they receive from the Moon, and which they tranſmit with them to the Earth, and for the ſame Reaſon, as the Earth is a Cold and Contractive Body, the Sun's Rays are ſuitably weaken'd by the Reflections from it; There is alſo obſervable a Glowing Brightneſs in the Moon, which is the Property of Light ſtrongly Reflected from Bright, Hard and Icy, or Metalline Bodies, but not from Earth and Graſs.

FROM all which we may Rationally believe and think, that the Moon is a Vaſt Globe or Craggy Rock of Solid and Compacted Salt, Chryſtal, or Metallick Ice, Infinitely Colder and Stronger than that which is produc'd here, by it's Influence only, at ſo many Thouſand Miles Diſtance, that it is Deſolate and Uninhabited, without Atmoſphere, as is Evident from the ſudden Immerſion of Stars into, and their Emerſion from behind it, and plac'd in the Heavens, as the Scriptures inform us, to Govern the Night, that is, to Communicate Light and Cold to us. The Face of the Moon is variouſly diſtinguiſh'd into Parts, ſome of which are Brighter, and the others more Obſcure, the Former of which are compar'd by Philoſophers to Rocks of Adamant, and large Prominences of Pearl and Chryſtal, and tho' ſome have fancy'd the Obſcurer Parts to be Seas and Lakes and Marſhes ſcatter'd about upon it's Surface, as in our Earth, yet, by the better Kind of Teleſcopes, they are found to be Huge Caverns, and void Cavities with the Shadows falling within them, both which Accounts perfectly agree with that Cold, Solid, Icy, and Chryſtal Nature, and the Prerupt and Cragged Figure, which we have aſſign'd it. And it is not certain but the Planets may be of the ſame Species, or at leaſt the Secondary ones.

Dr. Keill's Aſtronom. Lect. 10. Pag. 117.

An Account from hence of the Flux and Reflux of the Sea.

§. 22. FROM the Contractive Force of the Moon ariſes the Flux and Reflux of the Sea, which, by drawing the Waters towards it, makes them Lift and Heave from the Bottom, and from thence, by their proper Gravity, or the Contractive Force of the Earth, they fall downwards, and roll in Waves and Surges to the Shores, or deſcend into ſuch Rivers, which Communicate with the Ocean, and by the Moon's receding, and the Contractive Force being thereby diminiſh'd, the Waters ſink to their former Ebb; by which means the Flux and Reflux of them is Perform'd. Thus, let *S* Repreſent the Sun, *ABCD* the Moon in it's Orbit, *E* the Earth, which we at preſent ſuppoſe to be Quieſcent; When the Moon is in *A*, *g*, *l* are under the perpendicular or ſtrongeſt Influence of it's Contractive Force in *A*, and the Waters will accordingly ſwell to the utmoſt Height in *G*, and *L*; when the Moon is in *B*, *n*, *i*, will riſe to the utmoſt Height in *N*, *I*; when in *C*, from *l*, *g*, again to *L*, *G*; and when in *D* from *i*, *n* to *I*, *N*; in all which Caſes, when the Waters are rais'd in *G*, they will by their own Gravity, or the Contractive Force of the Earth, deſcend towards the Parts *F* and *H*, in *N* towards *F* and *M*, in *L* towards *M* and *K*, and in *I* towards *K* and *H*, which makes the whole Flux of the Waters, by which the Ocean is fill'd to the Shores of it, to the Height of ſeveral Feet, which may be eaſily conceiv'd, if we make the Parts lying above *H* and *F*, *F* and *M*, *M* and *K*, *K* and *H* to repreſent thoſe Shores; But as the Moon recedes from *A* to *B*, by which it's Contractive Force, becoming more Oblique to the Waters in *G*, will be continually Diminiſh'd and in *B* Inſenſible, the Waters in *FGH* will continually ſubſide by the Contractive Force of the Earth, till they fall to *FgH*, where they will be in their utmoſt Ebb, which is, what is call'd, the Reflux of them; and the ſame will happen to the Waters in *N*, when the Moon is in *C*, to the Waters in *L*, when the Moon is in *D*, and to thoſe in *I*, when the Moon is in *A*.



From what has been ſaid it is Manifeſt, that in the Moon's Revolution there will be Two Fluxes, and as many Refluxes to the ſame Part of the Earth, that is, Two Fluxes from *g* to *G*, when the Moon is in *A* or in *C*, and Two Refluxes, when in *B* and *D*; Two Fluxes from *n* to *N*, when the Moon is in *B* or in *D*, and as many Refluxes, when it is in *C* or *A*; Two Fluxes from *l* to *L*, when the Moon is in *C* or in *A*, and as many Refluxes, when in *D* and *B*; and laſtly, Two Fluxes from *i* to *I*, when the Moon is in *D* or in *B*, and as many Refluxes when in *A* and in *C*. Conſequently, every New and Full Moon, when, as in *B* and *D*, the Moon is in Conjunction with or in Oppoſition to the Sun, there will be Spring-Tides, or a Flux of the Sea from *n* to *N*, and when it is in it's Quadratures with it, the Tides will be Niepe, or upon the Reflux from *N* to *n*, which is affirm'd by thoſe, who are Coaſters upon the Sea, and have conſtantly obſerv'd them. And what has been ſaid of *n*, may be ſaid of *g*, *i*, and *l*, &c. when by their Diurnal Rotation they come to the ſame Syzygiæ.

An Hiſtory of the Tides on the Suſſex-*Shore.*

§. 23. Thus at *Worthing-Point* in *Suſſex*, in the Pariſh of *Broadwater*, where the Ocean lies Free and Open, and the Shore is one continu'd Flat for ſeveral Miles together, the Greateſt Flux or Full Sea is at 11 of the Clock in the Morning every New and Full Moon, and the Greateſt Ebb or Reflux 6 Hours after, namely, at 5 a Clock in the Afternoon; it is Full Sea every Day $\frac{3}{4}$ of an Hour and $\frac{1}{2}$ a Quarter later, namely, The firſt Day after New or Full Moon $\frac{3}{4}$ and $\frac{1}{2}$ a Quarter after 11 a

Clock in the Morning, The ſecond Day 1 Hour and $\frac{3}{4}$ after 11, and ſo on, ſo that in ſeven Days after New and Full Moon, Full Sea is about 6 Hours later than it is at the New or Full Moon, or 6 Hours and $\frac{1}{8}$; And in the Quadratures or Quarters of the Moon, or the Middle Time betwixt the New and Full Moon, the Greateſt Ebb is at 11 a Clock in the Morning, and the Greateſt Flow or Full Sea is at 5 in the Afternoon, and the Greateſt Ebb and the Greateſt Flow are always at 6 Hours Diſtance from one another.

At *Shoreham-Ferry*, which is upon the ſame Coaſt, but is an Inlet from the Sea into the Land, the Flow of the Sea is ſaid to be 4 Hours, and the Ebb 8, ſo that it is Full Sea at 11 a Clock in the Morning, every New and Full Moon, as before, and 8 Hours after, the Greateſt Ebb, or at 7 a Clock at Night, and 4 Hours after, Full Water again, that is, at 11 at Night, and Loweſt Ebb at 7 in the Morning, and Full Water at 11.

It is farther obſerv'd by theſe Coaſters, That the Spring-Tides at *Worthing-Point* are Three Days before and Three Days after the New and Full Moon, that they begin to Riſe or Lift, as they call it, the Third Day before the New and Full Moon, and continually encreaſe to the Third Day after the ſaid New or Full Moon, when the Greateſt Spring is, and when the Water is 10 Feet perpendicularly Higher than in the loweſt Niepe; Alſo that in theſe Low or Niepe Tides, which fall betwixt Spring-Tide and Spring-Tide, the Water continually Decreaſes from the higheſt Spring-Tide, and is half Niepe-Tide at the Moon's Quarters, from thence it ſtill Decreaſes, till it is the loweſt Niepe-Tide, the Day before the Spring-Tide begins to Lift, that is, the Fourth Day before the New or Full Moon; That likewiſe, the Spring-Tides move Faſter and Quicker, and the Niepe more Languidly and Slowly; And that, Laſtly, the Spring-Tides are Equal at the New and Full Moon, for, in both Caſes, the Water is 10 Feet Higher than in the loweſt Niepe.

Why there are Two Fluxes and Two Refluxes every 24 Hours.

§. 24. Let the Earth, which has been hitherto chiefly conſider'd as Quieſcent, be now revolv'd about it's Axis from *g* to *n*, and *l*, and when the Moon is in *A*, as before, the Waters will Riſe to *G* and *L*, and thoſe at *N*, and *I* will ſubſide to *n* and *i*, Let *i* by it's Revolution arrive at *g*, under the perpendicular Influence of the Moon in *A*, and the Waters will Riſe or Flow in *I* and *N*, and thoſe at *G* and *L* will ſubſide to *g* and *l*, and ſo of the Reſt; From whence it will follow, that in the ſame Place there will be every Day Two Fluxes and Two Refluxes of the Waters, namely, when *g* is directly under *A*, and in Conjunction with it, and when *g* comes to *l*, and is in Oppoſition to it, there will be a Flux of them, to *G* and *L*, and when *g* comes to *n* or to *i*, in it's Revolution, there will be a Reflux, to wit, when the Moon is in the Meridian above or below the Horizon of the Place, that is, in a perpendicular Situation to it, there will be the Greateſt Flow, and when it is in the Eaſt or Weſt, that is, in the Horizon, or in a Quadrate Situation with the Place, there will be the Greateſt Reflux.

And thus according to the Account, which the Coaſters give at the above-mention'd *Point*, When the Moon is North and South, as they Term it, that is, when it is in the Meridian below the Horizon, or in the Meridian above it, 'tis always High Water; when it is Eaſt or Weſt, that is, when it Riſes or Sets, it is always Low Water; When the Moon Riſes it is Low Water, which continually Increaſes till it comes to the Meridian, when it is High Water, and from thence Decreaſes till the Moon Sets, and then it is Low Water, after which it Increaſes till the Moon is in the Meridian below the Horizon, when it is again High Water, and from thence Decreaſes to the Riſing of the Moon, when it is Low Water; And the Water is equally High, when the Moon is in the Meridian Above or Below the Horizon.

Why the Water is equally High, when the Moon is in the Meridian Above or Below the Horizon.

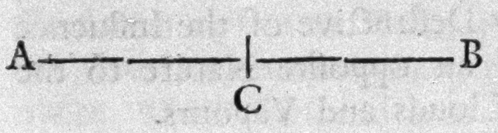
§. 25. The Main and Principal Difficulty here is to aſſign a Reaſon, why the Water Riſes to the ſame Height, when the Moon is in the Meridian above the Horizon, or in that Below it, by the ſame Contractive Force, that is, how it comes to paſs that whether the Moon is in *A* or *C*, the Water in the Diurnal-Tides always Riſes from *g* to *G*, ſince one wou'd think, that the ſame Contractive Force, which in *A* draws the Water from *g* to *G*, in *C* wou'd draw it from *G* to *g*; So likewiſe in the Spring or Monthly Tides, the ſame Effect is obſervable, when the Moon is in Conjunction with the Sun, or in Oppoſition to it, that is, when it is in *B* or in *D*, name-

D, namely, on the ſame Side of the Earth with the Waters, which are raiſ'd, or on the Oppoſite to them.

THE Solution of which can be no other than this, That when the Moon is in *A* in the Diurnal, or in *B* in the Monthly Tides, the Contractive Force of the Moon acting againſt the Contractive Force of the Earth, each of them Endeavours to draw the Waters to them, but by how much more the Contractive Force of the Moon is Superior to that of the Earth, by ſo much do's it prevail againſt it, and Elevates and Raiſes the Waters above that Situation or Poſition, which the Contractive Force of the Earth wou'd give them, and if the Moon and the Earth were to remain Quieſcent in *A* or *B*, and in *E*, the Waters wou'd continually ſtand at the Height of *G* or *N*, by the Superior Force of the Moon's Contraction, but as the Moon in *B* moves towards *C* in it's Monthly Revolution, and the Point *g* of the Earth towards *n* in it's Diurnal, the Contractive Force of the Moon is diminiſh't by ceaſing to be Perpendicular, and becoming Oblique, and the Contractive Force of the Earth prevails, upon which the Waters begin to flow from their Height, and to fill the Places below them, and at length to ſubſide; and this Struggle betwixt the Moon and the Earth continues quite round the Orbit of the one, and the Rotation upon it's Axis of the other.

FOR the ſame Reaſon, when the Waters lye on the oppoſite Side of the Earth to the Moon, ſince the Earth and Moon preſerve the ſame Diſtance from each other, the Difference of their Contractive Forces will be ſtill the ſame, namely, that of the Moon will be in the ſame Proportion Superior to that of the Earth, but as theſe Forces act Contrary to one another, the Superior Force, which was Attractive on this Side the Earth, will be Repulſive on the other; For if the Earth and the Moon, in this Poſition of the Waters, attracted them the ſame Way, they wou'd not be Actions contrary to each other, which by the former Phænomenon it is Evident they are, whilſt therefore the Earth attracts the Waters to it's Center, the Moon for the ſame Reaſon, by it's prevailing Force, will repel them from it on the other Side the Earth, to an Equal Height, as it drew them from it on this; for if theſe Two Actions are contrary to each other, it will be the ſame, whether the Earth draws the Waters one Way, and the Moon another, which is the firſt Caſe, or whether the Earth draws them the ſame Way, as the Moon did before, and the Moon the Contrary, that is, Repels them, which is the Second.

FOR thus, in any Two Equal Forces acting with contrary Directions, it will be the ſame, whether the Firſt Acts towards the Right Hand, and the Second towards the Left, or the Firſt to the Left, and the Second to the Right, for it is the ſame, whether *A* preſſes to the Right Hand upon the Point *C*, and *B* to the Left on the ſame Point, or whether *A* acts towards the Left, and *B* to the Right by Attracting the Point *C* Different Ways with Equal Forces, ſo that Two Contractive Forces, as thoſe of the Moon and Earth, Acting againſt each other, may be Repreſented by Two Forces Attracting one another with contrary Directions, as when the Moon is in *A*, and the Waters in *g*, or by Two Forces propelling each other with contrary Directions, as when the Moon is in *A*, and the Waters in *l*, or, which is ſtill the ſame, the Moon's Force may be conſider'd as a Propelling or Expanſive one from the Center *E* in the Earth, and the Earth's as a Gravitating or Contractive one towards the ſame Center, for one Contractive Force Acting in a contrary Direction to another, is the ſame as an Expanſive one in Reſpect of that Contractive.



Why the Spring or Monthly-Tides are the Greateſt in the Moon's Conjunction and Oppoſition with the Sun, and Niepe in the Quadratures.

§. 26. HAVING conſider'd the Moon in it's Revolution about the Earth, and the Earth's Revolution about it's Axis, and what Effect they have upon the Flux and Reflux of the Sea, it is Neceſſary to know whether the Sun has any Influence in theſe Tides, becauſe in the Conjunction and Oppoſition of the Moon with it, that is, when the Moon is in *B* or in *D*, the Spring or Monthly Tides or Fluxes are the Greateſt, and in the Quadratures of the Moon with the Sun, the Tides are Niepe, and which it is Certain it has for that very Reaſon, ſince this Increaſe of the Tides cannot proceed from the Moon's being in *B* or in *D*, that is in Conjunction or Oppoſition with the Waters, which are Raiſ'd, which it is every Day in the Diurnal ones, and yet no Spring-Tides are conſequent from thence; it muſt be therefore affirm'd, that the Sun has a Force and Efficacy in Raiſing the Waters, both when the Moon is in Conjunction, and when in Oppoſition with it, or rather that it is Aſſiſting to and Concurrs with the Force of the Moon in Raiſing of them, by whoſe Power that Effect is principally and properly produc'd.

THE Solution of which Phænomenon ſeems to be this, That as the Sun has Evidently a Great Expanſive Force, which always acts Contrary to the Contractive, ſo ſuppoſing the Moon in *B*, whilſt it by it's Contrary and Superior Contractive Force to that of the Earth Raiſes the Waters to *N*, the Expanſive Force from the Sun in *S*, Acting upon the the ſame Waters, Diminiſhes their Contractive Force, tho' it is impreſs'd with the ſame Direction, that is, Tends towards *E*, the ſame Way as the Contractive Force of the Earth or Waters do's, but notwithſtanding it's Tendency of Exertion is the ſame Way, yet ſince it's Force is of a Different Nature, it will weaken that Force which is of a Contrary one; thus tho' we ſtrike a Ball to the Earth, and the Force of Percuſſion acts the ſame Way with that of Gravitation, yet the Effect of Gravitation obtains Leſs, as the Force of Percuſſion is Greater, becauſe Percuſſion is an Expanſive Force Different from that of Contraction or Gravitation; ſo likewiſe in Fire, which exerts it ſelf all Ways, and conſequently Downwards, that is the ſame Way which Bodies Gravitate, the Force of Gravitation or Contraction is yet weaken'd by it, as Solid and Heavy Bodies are by it chang'd into a Light Cinder.

THE Expanſive Force therefore of the Sun concurrs with the Moon's Contrary and Contractive Force to the Earth, which, as has been ſhewn, may be conſider'd as a kind of Expanſive, in Raiſing the Waters and Diminiſhing the Force of the Earth's Contractive, That is, an Expanſive Force, as of the Sun, Acting upon a Contractive, as of the Earth, the ſame Way, and in the ſame Direction of it's Force, may be eſteem'd a Repulſive or Expanſive one from the Center *E*, in Compariſon of the Earth's Contractive, which Tends and Preſſes towards it.

AND for the ſame Reaſon, when the Moon is in *D*, or in Oppoſition with the Sun, the Effect will be ſtill the ſame, the Sun continuing in the ſame Situation as before, in Reſpect of the Waters in *n*, and it has been already prov'd, that the Moon's Power will be alike in *D* or in *B*.

LASTLY, when the Moon is in *D*, and the Waters are rais'd at *I*, the Expanſive Force of the Sun will have the ſame Effect, whether it Acts in the ſame Tendency and Direction with the Earth's Contractive Force, that is, from *n* to *E*, or in a Contrary one to it, that is, from *E* to *i*, for they will be both Repulſive of the Earth's Contraction, the firſt will be repreſented by a Percuſſion to the Center *E*, and the other by a Percuſſion from it, and both equally Deſtructive of the Influence and Power of Gravitation, or that Force, which is of an oppoſite Nature to the Expanſive, for by this it is, that Waters are rais'd into Clouds and Vapours.

The Laws of the Expanſive and Contractive Forces.

AND from what we have ſaid, we may lay down theſe General Rules in Reſpect of the Expanſive or Contractive Forces.

1. THAT a Contractive Acting in Oppoſition to a Contractive, is the ſame, as an Expanſive Force Acting from a Center, and a Contractive Acting towards one.

2. THAT an Expanſive Force Acting the ſame Way with or in an Oppoſite to a Contractive, is the ſame as a Contractive Acting in Oppoſition to a Contractive, or an Expanſive Force Acting from a Center, and a Contractive Acting towards one.

3. THAT an Expanſive Force Acting in Oppoſition to an Expanſive Force, is the ſame, as a Contractive Acting againſt a Contractive, or as an Expanſive Force Acting from a Center, and a Contractive towards one.

4. THAT an Expanſive Force Acting the ſame Way with another Expanſive Force, or a Contractive the ſame Way with another Contractive, is the ſame, as Increaſing the Expanſive Force from the ſame Center, or Increaſing the Contractive towards one.

How the Sun's Expanſive Force, and the Moon and Earth's Contractive ſolve all the Phænomenons of the Tides.

§. 27. WHAT Remains now is to ſhew, how this Theory of the Sun's Expanſive and the Moon's Contractive Force is anſwerable to the Obſervations in Fact, before recounted; And firſt it is from hence Evident, that on every Full and New Moon, the Tides will be the Greateſt, that is, when the Moon is in Conjunction or Oppoſition with the Sun, and that they will be Niepe or not up, when it is in the Quadratures with it; They will alſo be at the Greateſt Ebb, 6 Hours after they are at the Fulleſt, by the Earth's Revolution about it's Axis, for if the Waters are at their Height in *N* or in *I*, when *n* by it's Revolution comes to *l*, or *i* to *g*, which will be in 6 Hours, and, when the Sun and Moon will have the leaſt Influence to raiſe them by their Oblique Actions, they will accordingly ſubſide to the loweſt Standard; It will likewiſe be Full Sea $\frac{3}{4}$ of an Hour and $\frac{1}{2}$ a Quarter later every Day from the Full or New Moon, ſo as in 7 Days after, it is 6 Hours or 6 Hours $\frac{1}{8}$ later than in the Full or New Moon;

HENCE it is, that the Monthly and Diurnal Tides do agree, for as Full Sea is at *N*, when the Moon is in *B* or in *D* at thoſe Tides, ſo it is at the loweſt Ebb 6 Hours after, that is, when by the Revolution of the Earth about it's Axis *n* arrives at *l*, or *i* at *g*. And thus it is in the Spring and Niepe or Monthly Fluxes and Refluxes, for in the Conjunction of *B* with the Sun or in the New Moon, and it's Oppoſition at *D* or in the Full, the Spring-Tides are obſerv'd, and 7 Days after the half Niepe, which is nearly the ſame in the Moon's Revolution about and Receſs from the Sun, as 6 Hours in the Diurnal Revolution of the Earth about it's Axis, and the Receſs of the Parts of the Earth from the Moon; that is, in both Caſes, the Moon is Perpendicular to the Earth in the Greateſt Diurnal Tides, and in $\frac{1}{4}$ Part of the Earth's Revolution about it's Axis, that is, in 6 Hours, the loweſt Ebb is, and in the Monthly or Spring and Niepe-Tides, the greateſt Spring Flow is, when the Waters are under the perpendicular Influence of the Sun and Moon, and the leaſt Spring Flow or half Niepe, in $\frac{1}{4}$ Part of the Moon's Revolution in it's Orbit or Receſs from the Sun, which is in 7 Days nearly, it being 29 Days and $\frac{1}{2}$ in paſſing from the Sun to it's following Conjunction with it; from thence they fall Gradually, till they are at the loweſt Niepe the fourth Day before the New or Full Moon, and, the Day after, the Spring-Tides begin to riſe.

THAT the Full Tide is $\frac{3}{4}$ and $\frac{1}{8}$ of an Hour later every Day after the Full or New Moon, ſeems to be from hence, that, the Moon paſſing about $\frac{3}{4}$ and $\frac{1}{8}$ of an Hour every Day from Weſt to Eaſt in it's Menſtrual Revolution, it poſſeſſes a Meridian, which is $\frac{3}{4}$ and $\frac{1}{8}$ of an Hour Eaſtward of the former, and therefore, whilſt the Earth is carry'd Round upon it's Axis from Weſt to Eaſt likewiſe, it will be $\frac{3}{4}$ and $\frac{1}{8}$ of an Hour later, before the ſame Part of the Earth comes to the Moon's Meridian, and thus in 7 Days Full Sea is about 6 Hours later than in the Full and New Moon, for $7 \times \frac{3}{4} + \frac{1}{8} = 6$ Hours $\frac{1}{8}$; The Moon farther Proceeds 13° to the Eaſt every Day, which Reſolv'd into Time, Meaſur'd by the Earth's Revolution about it's Axis, which Performs 15° in an Hour, is $\frac{13}{15}$ of an Hour $= 3\frac{7}{15}$ divided by $4 = \frac{3}{4} + \frac{1}{8}$ nearly.

THAT at *Shoreham-Ferry* the Sea Flows 4 Hours and Ebbs 8, is, becauſe the Waters there, which Deſcend into the Sea, lie Higher than the Ocean, ſo that Two Hours are ſpent in raiſing the Ocean to a Level with them, which from thence begins to Flow and Deſcend upon them for the Remaining 4 Hours of it's Flux; On the Contrary, the Waters at the *Ferry* will Return more ſlowly than thoſe in the Ocean, becauſe, when rais'd by the Flux, they do not ſtand ſo High and Steep above their Natural Situation, as the Waters of the Ocean, and therefore will not Precipitate ſo faſt, and likewiſe, becauſe they are met in their Regreſs by the Sea, which is now a ſecond Time upon it's Flow to reduce it ſelf to a Level with them; And this will give a Solution of all the like Phænomenons obſervable in the Fluxes and Refluxes of Rivers Different from thoſe of the Ocean. See alſo §. 29.

FROM hence it is alſo manifeſt, why the Waters begin to Riſe or Lift three Days before the Full or New Moon, and are continually Increas'd to the third Day after, when they are at the utmoſt Height, becauſe the Actions of the Sun and Moon are too oblique to obtain any conſiderable Influence till that Time, and their Force is Increas'd even after they are the moſt Perpendicular, that is, in the Full or New Moon, becauſe thoſe Impreſſions ſtill remain, to which are added the Subſequent ones; Thus the Sun's Force in Summer, is more ſenſible ſome Time after it has been in the Tropick, than when it is in the Tropick it ſelf.

FOR the ſame Reaſon, as the Moon recedes from that Perpendicular Influence, or from three Days after the Full or New Moon, the Waters will continually Fall, and when the Moon is in it's Quadratures, or in the Middle way betwixt Full and New Moon, they will be half Niepe, and the loweſt Niepe will be the Day preceding the third Day before the Full or New Moon, that is, the fourth Day before it, See §. 31.

ing the Sun and Moon have little or no Effect till they are nearly in Conjunction with or Oppoſition to one another, not becauſe they deſtroy each others Effects, ſince they concur in their Actions, but becauſe the Sun has little Power to raiſe the Waters unleſs in Concurrence with the Moon; And that the Spring-Tides will be Equal at the New or Full Moon has been already ſhewn, becauſe their Expanſive and Contractive Forces will be in both Caſes Equal.

LASTLY, the Waters move Faſter in the Spring than in the Niepe-Tides, becauſe the Forces of the Sun and Moon, which Actuate them are Greater, by which they are rais'd Higher and Quicker, and deſcend with more Violence from ſuch Elevation to the Shores. What has been ſaid here, in Reſpect of the Tides at *Worthing-Point* and *Shoreham*, will be Applicable to any other, allowing for the Different Circumſtances of the Place or Ocean. Thus far we had Writ, before we had ſeen Sir *Iſ. Newton* on this Head.

An Examination of the preſent Celebrated Philoſophy of Tides, by the foregoing Explanation of Them. Sir Iſ. Newt. Princip. Prop. 24. Lib. 3.

§. 28. FROM the Doctrine of Tides before deliver'd, and which is confirm'd by the conſtant Obſervation of the Coaſters upon the Sea, which waſhes the Shores of *Suſſex*, we may be enabled in ſome Meaſure to Judge of what is propos'd to us from the preſent Celebrated Philoſophy, which very much ſupports our Opinion.

AND firſt it is plain from hence, which is there Affirm'd, that the Sea, every Lunar and Solar Day, or every Revolution of any Part of the Earth from the Moon or Sun to the ſame Luminaries, ought to have and really has Two Fluxes and Two Refluxes, but then we muſt farther add, that ſo it wou'd have, if the Moon was only conſider'd in this Revolution, tho' they wou'd not be altogether ſo Great, the Sun only Aſſiſting by it's Expanſive Force, what is principally perform'd by the Moon's Contractive, according to what has been already Explain'd, and if that Expanſive Force of the Sun was Abſent, the Contractive of the Moon wou'd raiſe the Waters to nearly the ſame Height, ſince the Expanſive Force of the Sun only Facilitates the Moon's Operation.

SECOND, It is not yet ſo Evident, what the preſent Philoſophy likewiſe Aſſerts, that the Greateſt Height of the Waters in Seas, which are Free and Open and Deep, follows upon the Appulſe of the Luminaries to the Meridian of the Place in Leſs than 6 Hours, and that in the *Atlantick*, the *Æthiopick*, and *Pacifick* Ocean, the Greateſt Tides or Fluxes at the Shores are about the Third Hour after ſuch Appulſe, Reckoning an Hour to be the 24*th* Part of the Moon's Apparent Revolution from to the ſame Meridian.

BECAUSE we take the Diurnal Tides, according to the Account foregoing, to proceed from the Appulſe of the Moon to the Meridian, and that they are then or thereabout the Greateſt, that is a Little after ſuch Appulſe, that 3 Hours after they Decline, and in 6 Hours entirely Sink, as is plain in Fact from what is affirm'd on the Coaſts of *Suſſex*, and for which there has been a Reaſon given.

THIS cannot be attributed to the Streightneſs of the one Sea in Reſpect of the others mention'd, ſince tho' it is not ſo Large, it is yet as unreſtrain'd and unconfin'd as any other can be, it lies within it's Chanel to a great Diſtance from the Shore, and has a Plain, Flat, and Even Strand for ſeveral Miles together, it do's not Riſe or Move, but as the Moon comes to the Meridian of the Place above or below the Horizon, and do's not owe the Flux of it's Waters to any others pouring in upon it.

Why on the Shores of the Atlantick, *the* Æthiopick, *and* Pacifick *Oceans, the Greateſt Tides or Fluxes are about the Third Hour, after the Appulſe of the Moon to the Meridian.* Sir Iſ. Newt. Princip. Prop. 24. Lib. 3.

§. 29. ON the other Hand, what can be ſaid, when it is as Punctually maintain'd, that upon the Shores of the *Atlantick*, the *Æthiopick*, and the *Pacifick* Ocean, the Greateſt Tides or Fluxes are about the Third Hour, after the Appulſe of the Moon to the Meridian, that is, when it is in the Mid-way betwixt the Meridian and Horizon? The Reaſon of which is Probably this, that the Greateſt Height of the Waters in the Ocean is to be diſtinguiſh'd from the Greateſt Height of them at the Shores, the firſt proceeding from the Appulſe of the Moon to the Meridian, and the laſt from their Flowing down from that Height by their proper Gravity to the Shores below them, the Elevation of the Waters, in the former Caſe, is Common to the Ocean every where, which is conſtantly rais'd to the utmoſt Height upon the Moon's Appulſe to the Meridian, or preſently after, but the Elevation of the Waters, in the ſecond Caſe, is owing to the Deſcent of them from that Height, and being yet in Part ſuſtain'd by the Moon's Contractive Force, which Deſcent will be in a Greater or Leſs Time, as the Shores are Nearer or Farther Remov'd from the above-mention'd Height; And this will give an Account why the utmoſt Tides and Fluxes in Rivers, which communicate with the Ocean, may be at Different Times after the Elevation of the Waters by ſuch an Appulſe. This Philoſophy ſeems only to conſider the Former, namely, the Riſe of the Waters in the Ocean, and not to make any Diſtinction of it from the Latter, or the Riſe of them at the Shores, whereas they proceed from very Different and Contrary Cauſes, the firſt from the Moon's Contraction, and the laſt from the Earth's. It may be added, that as the Sun's Expanſive Force is Greateſt betwixt the Tropicks, ſo is the Contractive of the Moon, and about 5° beyond Them, under which Tract of the Heavens the aforeſaid Oceans lie, for our Winters ſeem to be caus'd by frequent Returns of the Moon to our Tropick, whilſt the Sun Retires to the other; and therefore, the Waters, being ſuſpended by a Greater Contractive Force of the Moon, are not permitted to Deſcend to the Shores, till that Force is Impair'd ſome Time after the Departure of the Moon from the Meridian, that is, at ſome Diſtance from it.

How our Winters are produc'd from the Contractive Force of the Moon, as our Summers by the Expanſive of the Sun.

§. 30. The ſecond Thing aſſerted in this Philoſophy is, That the Two Motions, which are Excited by theſe Two Luminaries, are not ſeparately Diſcernible, but produce a certain mixt Motion, and that in the Conjunction or Oppoſition of them, or their Syzygiæ, their Effects will be join'd and united by which the Greateſt Flux and Reflux will be Caus'd, which has been already ſufficiently explain'd from the Expanſive Force of the Sun, and the Contractive of the Moon, and that the Former is Inconſiderable compar'd with the Latter; and ſo it is likewiſe in Reſpect of it's Heat, which is not able to diſſolve, with all it's Force, the Ice and Snow, which lie in the *Northern* Seas and on the Tops of the higheſt Mountains, produc'd, as was before ſhewn, by the Moon's Influence.

The Action of the Sun Inconſiderable in Raiſing the Tides in Reſpect of that of the Moon.
Sir Iſ. Newt. Princip. Prop. 24. Lib. 3.

§. 31. The third Aſſertion is ſomething Extraordinary, and which is found in both the Editions of this Philoſophy, that in the Quadratures the Sun will Raiſe the Water, where the Moon Depreſſes it, and will Depreſs it, where the Sun Raiſes it, and from the Difference of their Effects, the leaſt Flux and Reflux will ariſe; which, in a Grammatical Conſtruction, is as much as to ſay, that the Sun will Raiſe the Water, where the Moon Depreſſes it, and the Sun will Depreſs it, where the Sun Raiſes it, which is a Contradiction, or elſe in a leſs Grammatical one, the Sun will Raiſe the Water, where the Moon Depreſſes it, and the Moon will Depreſs it, where the Sun Raiſes it, which is a Tautology.

The Elevation of the Waters in the Syzygiæ, and the Depreſſion of them in the Quadratures illy explain'd by the Modern Philoſophy.
Sir Iſ. Newt. Princip. Prop. 24. Lib. 3. Edit. 1, & 2.

What I ſuppoſe is meant, is this, that as the Greateſt Flux and Reflux is in the Syzygiæ, ſo the Leaſt is in the Quadratures, and that, where each of theſe Luminaries Act perpendicularly, they will have the Greateſt Force to Raiſe the Waters, either jointly, as in the Syzygiæ, or ſeparately, as in the Quadratures, and where the moſt Obliquely the Leaſt, as the Sun in Reſpect of the Waters, which lie under the Moon in it's Quadrature, and the Moon in Reſpect of the Waters, which lie under the Sun in that Quadrate Situation, which is a perfect Axiom, and has been before Accounted for. As to what is farther alledg'd concerning the Forces of theſe Luminaries, betwixt the Syzygiæ and the Quadratures, it do's not need to be here conſider'd, ſince it entirely Depends upon what foregoes.

§. 32. And the Reaſon, why the ἀκμὴ of the Waters is later in Rivers, which Communicate with the Sea, than in the Shores of it, do's not ſo much proceed from their Shallows, nor from the Streightneſs of ſuch Paſſages, thro' which the Waters are convey'd, as from the Diſtance they have from the Height of the Waters rais'd in the Ocean by the Appulſe of the Moon to the Meridian, and from the Height of thoſe Rivers in Reſpect of the Ocean, which being Different, the Times from the Appulſe of the Moon to the Meridian, will be Various, in which the Waters of the Ocean deſcend into the Rivers, in order to produce betwixt them one uniform Level firſt, and after, a Flux of the one upon the other.

Why the ἀκμὴ of the Waters is later in Rivers, which Communicate with the Sea than on the Shores of it.
Sir Iſ. Newt. Princip. Prop. 24. Lib. 3.

§. 33. 'Tis true the Effects of theſe Luminaries do alſo depend upon their Diſtances from the Earth, ſo that in leſſer Diſtances their Effects are Greater, and in Greater Leſs, but perhaps not in that Reaſon and Proportion, which is here aſſign'd, that is, in a Triplicate one of the Apparent Diameters, ſince we have before ſhewn what little Reaſon there is to depend upon a Computation from ſuch Diſtances, where the Diſtances themſelves are ſo Precarious and Uncertain, however we may in General ſay,

The Greateſt Tides will be when the Two Luminaries are in their Syzygiæ, and in their Perigeums.
Sir Iſ. Newt. Princip. Prop. 24. Lib. 3.

ſay, that in Winter, when the Sun is in it's Perigeum, it produces Greater Effects, and makes the Tides riſe Higher, tho' very little, than in Summer, becauſe of it's ſmall Expanſive Force in Reſpect of the great Contractive one of the Moon; as alſo, that the Moon every Month, in it's Perigeum, excites Greater Tides than fifteen Days before and after, when it is in it's Apogeum; From whence it comes to paſs, that the Two Greateſt Tides or Fluxes of all, cannot follow one another in any Two ſubſequent Syzygiæ: For ſuppoſing the Sun and Moon to be in their Perigeums, when they are in their Syzygiæ, the Greateſt Æſtus or Tide will enſue, but in the next Syzygiæ it is plain, that both of them will not be in their Perigeums, nor in the Syzygiæ following the former, and ſo on; that is, the Greateſt Tides will be, when the Sun and Moon are in their Syzygiæ, and when both of Them are in their Perigeums, and not otherwiſe.

The Reaſon why the Tides are Greater about the Æquinoxes than the Solſtices. Sir Iſ. Newt. Princip. Prop. 24. Lib. 3.

§. 34. If the Moon, whoſe Effect is Chiefly and Principally to be conſider'd, were plac'd in the Pole, and without any Motion, it is certain, by what we have alledg'd in the Doctrine of Tides, that by it's Contractive Force, which is Superior to that of the Earth's, it wou'd draw the Waters towards it, and they wou'd not Deſcend at all, and conſequently, there wou'd be no Reciprocation in the Motion of the Waters, or any Flux or Reflux of them; But, when this is confeſs'd by the preſent Philoſophy, it muſt likewiſe acknowledge, which we contend for, that the Contractive Force of the Earth and the Motion of the Moon from the Meridian are the Cauſe of the Flux of the Waters to the Shores, by the firſt of which they are made to Deſcend from the Height, to which the Moon in it's Meridian had rais'd them, and by the laſt the Perpendicular and Contractive Force of the Moon is weaken'd and diminiſh'd ſo far, as to allow the Waters to Deſcend from their Height, and to give the Contractive Force of the Earth the Prevalence; and when the Moon is ſtill farther remov'd from the Meridian, the Waters Sink from the Shores and return to the Ocean by the Contractive Force of the Earth ſtill more Prevailing; and the Reciprocation of the Waters proceeds from the Mutual and Reciprocal Attraction, by the Moon and Earth, of the Waters from the Earth and Shores towards the Moon, and from the Moon towards the Earth and Shores.

It is, notwithſtanding, but illy infer'd from a Suppoſition of the Moon's being fixt in the Pole, and obtaining no Reciprocation of the Waters there, that it's Effect and the Sun's is diminiſh'd, the farther they Decline from the Æquator, and the nearer they Approach to the Pole, and therefore, that the Tides are leſs in the Solſtitial than in the Æquinoctial Syzygiæ; For it wou'd be the ſame, if the Moon was ſuppos'd to remain Immoveable in the Æquator, and the Earth not to be Revolv'd, that is, there wou'd be no Fluxes or Tides, but the Water wou'd continue ſuſpended without any Reciprocation or Motion; It wou'd yet be a hard Inference from thence to affirm, that the Flow of the Waters wou'd be the Greater, the farther the Moon was Diſtant from the Æquator, and therefore, that the Tides are Greater in the Solſtices than in the Æquinoxes; notwithſtanding which, this may be as well Infer'd as the other, ſince we may as well ſuppoſe the Moon to ſtand ſtill in the Æquator, and the Earth to be Quieſcent upon it's Axis, as Imagine the Moon to be fixt in the Pole.

In Truth, there is no Connexion at all betwixt the Suppoſition and the Inference, betwixt the Waters being ſuſpended, and their being ſuſpended to a Higher Degree (which they muſt be in Greater Fluxes) the farther they are from ſuch a Suſpenſion; For where is the Force of this Concluſion? The Waters will be ſuſpended, if the Moon is ſuppos'd to be in the Pole, therefore they will be ſuſpended Higher in the Solſtices, and yet Higher in the Æquator; The Waters are Quieſcent, where the Moon is ſo in the Pole, therefore the Fluxes will be Leſs in the Solſtices, and Greater in the Æquator, becauſe the Moon is not there Quieſcent; How are the Degrees of the Fluxes aſcertain'd from the Moon's not Moving at all in the Pole, and Moving in the Æquator?

The Reaſon therefore, why the Tides are Greater about the Æquinoxes than the Solſtices, is; First, Becauſe when the Earth or Sun is in the Plane of the Æquator, the Moon and it's Orbit will more nearly Coincide with that Plane, than when the Earth and it's Moon is in the Greateſt Declination from it, that is in the Solſtices, and conſequently in the firſt Caſe, the Moon will be in a more Exact Conjunction and Oppoſition with the Sun, than in the Laſt, by which the Waters will be proportionably raiſ'd, in like Manner, as they are in the Monthly Syzygiæ; or the Luminaries, Acting more perpendicularly in the Æquator than in the Solſtices, will produce a Greater Effect upon the Waters in the one Circumſtance than in the other.

Second, Becauſe the Waters at the Æquinoxes are in the fitteſt Temper and Diſpoſition to be raiſ'd, as being then in the utmoſt Fluidity; In Winter they are Dull and Torpid, and in ſome Seas to that Degree, as to be Frozen into Ice, and as Ice cannot be raiſ'd into a Flux by the Moon, ſo any Approaches of the Waters to that Phlegmatick State will render them in ſome Meaſure Averſe and Reluctant to the Impreſſions of it; In Summer (ſince the Moon can no more raiſe Fire than Ice into a Flux) they are too Heated and Fiery, and by that Means likewiſe are leſs Obedient to the ſame Contractive Impreſſions; but in Spring and Autumn both theſe Obſtructions are Remov'd, and they in Conſequence riſe with Greater Freedom and Eaſe upon the Application of the Moon's Force to them.

Why the Tides are Greater in the Solſtitial Quadratures than in the Æquinoctial ones.
Sir Iſ. Newt. Princip. Prop. 24. Lib. 3.

§. 35. On the Contrary, the Tides are Greater in the Solſtitial Quadratures than in the Æquinoctial ones, becauſe in the Solſtitial Quadratures, the Sun is in the Tropicks, and the Moon in the Æquator, by which the Former will have the Leaſt, and the Latter the Greateſt Influence, and in the Æquinoctial Quadratures, the Sun will be in the Æquator, and the Moon in the Tropicks, by which the Former will have the Greateſt Influence, and the Latter the Leaſt, and therefore ſince the Moon's Contractive Force has the Greateſt Effect in Raiſing the Waters, the Tides will be the Greateſt in the Solſtitial Quadratures, and the Leaſt in the Æquinoctial ones: The Sum of All is, The Tides are the Greateſt in the Æquinoctial Syzygiæ, becauſe the Sun and Moon are then in the Æquator, or the neareſt to it, and Leſs in the Solſtitial Syzygiæ, becauſe they are then in the Tropicks, in which they have the leaſt Force; and the Tides are Greateſt in the Solſtitial Quadratures, becauſe the Sun is in the Tropicks, and the Moon in the Æquator, and Leſs in the Æquinoctial Quadratures, becauſe the Sun is in the Æquator, and the Moon in the Tropicks; which exactly Correſponds and Agrees with what we have before affirm'd, and is a full Conviction of our Doctrine of the Expanſive and Contractive Forces. From whence it follows, as is aſſerted in this Philoſophy, that the Greateſt Tides fall on the Syzygiæ, and the Leaſt on the Quadratures about the Times of the Æquinoxes, and that the Greateſt Tides in the Syzygiæ are follow'd by the Leaſt in the Quadratures, which is alſo found by Experience.

Why the greateſt and leaſt Tides oftner precede the Vernal Æquinox than follow it, and oftner follow the Autumnal than precede it.
Sir Iſ. Newt. Princip. Lib. 3. Prop. 24.

§. 36. That the Greateſt and Leaſt Tides oftner precede the Vernal Æquinox than follow it, and oftner follow the Autumnal than precede it, is not owing ſo much to the leſs Diſtance of the Sun from the Earth in Winter than in Summer, which has an Inconſiderable Effect in Raiſing the Waters, and is only Concurring and Aſſiſting to the great Action of the Moon, as firſt to the fuller Power and Force, which the Moon has in Winter than in Summer, by which it Harden's and Contracts Seas into Ice, which ſhews a Greater Force than Raiſing of them in the Flux; and ſecond, becauſe the Waters are more diſpos'd to be Elevated in the Colder than in the Hotter Seaſons of the Year, which is the Reaſon that there is more Rain in Winter, and in Spring, and Autumn, than in the Summer, that is, they are more Fluid, excepting in Froſt, than in the Summer, when their Parts are rather in a Tumult and Ferment and heated into a Degree of Fire, than paſſive and yielding to any Force which ſhall be impreſs'd upon them; And it is not impoſſible or unlikely but rather certain, that the Quantities of Waters raiſ'd, and which fall in the Year, are not only to be Attributed to the Sun's, but to the Moon's Action, by which it is capable of Raiſing whole Mountains of them in the Ocean, and that the Expanſive Force of the Sun, by diſſolving the Contractive of the Moon, or the Moon's Contracting what the Sun has Diſſipated and Exhal'd, is the Occaſion of their Falling, and which may be the Reaſon, why there is the Greateſt Plenty of Showres in Spring and Autumn. As to the ſecond Cauſe alledg'd for heightening the Waters in the Æquinoxes, namely, the Temper and Diſpoſition of them, that do's not obtain in the Solſtitial Quadratures, becauſe the Waters may be made too Fiery and Expanſive from the Solſtice for an Elevation by the Moon's Contractive.

If the Modern Doctrine of Attractive Forces was

§. 37. The Doctrine we have propos'd concerning the Contractive Power of the Moon and the Expanſive of the Sun, if carefully conſider'd, may be apply'd to what follows in this Philoſophy, and by which we may judge, where it Deviates

True, the Sun, Moon, Earth, and Planets, wou'd fall to one another. Sir Iſ. Newt. Princip. Prop. 25. 36, 37. Lib. 3. Sir Iſ. Newt. Optical Queries.

from the Truth, and where it Agrees with it; As to the Calculations of the Sun's and Moon's Force in Raiſing the Waters, they depend upon Principles, which ſeem to be falſe in themſelves, and therefore I ſhall not particularly conſider them, that is, of an univerſal Attraction of Bodies to each other, which, if true, if the Sun attracted the Earth, and the Earth the Sun, if the Moon attracted the Earth, and the Earth the Moon, as is ſuppos'd in this Philoſophy, what ſhou'd hinder the Moon's Deſcending to the Earth, and the Earth to the Sun? what ſhou'd obſtruct all the Planets falling together, and uniting in one Body with it, unleſs we introduce an Imaginary and Projectile Force to keep them up from ſuch a Tendency? On the Contrary, the Sun has an Expanſive and Diſſipating Force, as is Evident in Fact, the Earth has a Contractive, as is Evident from Gravitation, and the Moon has a Contractive, but which acts in a quite contrary Direction to that of the Earth, as is manifeſt from the Tides produc'd by their Contranitent Forces.

The Revolutions of the Moon about the Earth, and the Planets about the Sun, accounted for from theſe Principles.

§. 38. As therefore we plainly find, that a Motion or Revolution of Waters is effected by Two contrary Forces contending with each other, and as the Waters obey the Contractive Force of the Moon or the Earth, as the one or the other becomes Superior, ſo it is neceſſary that the Moon it ſelf, as it's Contractive Force is Superior, ſhou'd either draw the Earth to it, or Revolve round it, for that Superiority of Force muſt be ſpent ſome Way, and ſince it cannot attract the Earth to it, it muſt therefore move about it; thus in any Two contrary Forces, as that of a Sling thrown round upon a Center, if the Centrifugal Force, which proceeds from the Expanſive of the Mind, is Greater than the Centripetal of the Stone, a Revolution will be perform'd about the Center which detains it, and we have ſhewn, that Two Contractive Forces Acting in Oppoſition to each other are the ſame as a Centrifugal and a Centripetal. For the ſame Reaſon the Planets will Revolve round the Sun, the one having an Expanſive Force and the other a Contractive, that is Two contrary ones, if the Contractive is Superior to the Expanſive; from whence ariſes that Equal Poiſe we before aſſerted amongſt the Heavenly Bodies of the Moon with the Earth, and the Planets with the Sun, the Exceſs of their Forces being ſpent in their Revolutions. And from whence is Evident, the Infinite Wiſdom of the Almighty Diſpoſer, who weighs the Heavens as in a Balance, and Adjuſts Millions of Syſtems, beſides our own, according to the ſtricteſt Laws of Proportion and Reaſon.

Why River and Spring Waters are not rais'd into Tides as the Ocean is.

§. 39. From the Contractive Force of the Moon an Account may likewiſe be given, why Rivers are not Elevated in Fluxes, but yet may be Frozen by it; They cannot be rais'd in Tides or Fluxes for Two Reaſons, becauſe the Contractive Force of the Earth encloſes them too nearly, and becauſe the Vivacity and Spring of thoſe Running Waters, by which they Approach nearer to a Fiery or Expanſive Force, makes it, that they are leſs Obedient to, or capable of the Impreſſions from the Contractive Force of the Moon, whereas the Ocean lies at large from the Shores, and is of a Saltiſh and Contractive Nature, and is therefore more liable to the Actions of a Body, as the Moon, to whoſe Nature it more Approaches; For this muſt be acknowledg'd as an univerſal Principle, that the nearer any Bodies Approach to each other in the Quality of their Forces, the more Ready they are to Unite, and the more Contrary thoſe Forces are, as the Expanſive and Contractive, the more Averſe they are to ſuch an Union, as may be prov'd by a Thouſand Inſtances.

Why Ice is Lighter than Water, and Rivers or Seas, which are Frozen, riſe in Height, and are Contracted from the Banks or Shores, and why ſome Winters are Sharper than others.

§. 40. From the Contractive Force of the Moon it is alſo Evident, why Rivers are rais'd and ſwell'd by being Frozen, that is, why Ice is Lighter and takes up a Greater Space than Water, becauſe the Influence and Contractive Force of the Moon being Superior to that of the Earth, in the utmoſt Efforts of it in Froſt, both Contracts the Water from the Banks of Rivers, or the Shores of Seas, which are Frozen, and Heightens and Raiſes them from the Earth; and it is not Impoſſible but very Probable, that the Moon in it's Libration or Æquiponderance with the Earth, ſometimes comes much nearer to us than what is allow'd by the Calculations of Aſtronomers, who do not nor have conſtantly obſerv'd it's Motions, in which Caſes harder and ſharper Winters will be produc'd.

Why Lunaticks are more particulary ſubject to the Moon's Influence.

§. 41. From the ſame Contractive Force of the Moon it is, that Melancholy Perſons are more liable to it's Influences than thoſe whoſe Animal Spirits act with Greater Fire, Life, and Vivacity; the Dull and Languid of the one being more capable of being Affected by the Moon than the Brisk, Fiery, and Expanſive ones of the other; and thus no one ever knew a Man Diſtracted with Joy and with Chearfulneſs, where the Spirits and Blood move Briskly, but a Thouſand have been with Grief and with Sorrow, where their Force has more of the Contractive than the Expanſive; Which ſeems to be the Caſe alſo of the Hydrophobia.

Different Contractive Forces in Nature, and the Inſtances of Them.

§. 42. Having thus far confirm'd the Contractive Force of the Moon from ſeveral Inſtances, it will be now neceſſary to proceed to other Contractive Forces; That of the Earth is leſs than that of the Moon, as we have already evinc'd from the Tides occaſion'd by their Mutual Conflicts; the Contractive Force of one Planet we may reaſonably conclude is Greater than that of another; the Contractive Force of Snow is Greater than that of Rain, of Hail than that of Snow, of ſharp Froſt than that of Hail; the Contractive Force of Gold is Greater than that of Silver, of Silver Greater than that of Copper or of Iron, ſuppoſing the Expanſive Equal; and if theſe Bodies were plac'd at any Diſtance from each other, without the Earth's Intervention, they wou'd for the ſame Reaſon ſhew and exert their Particular Forces of Contraction, as much as we Experience the Earth and Moon do; and if their Contractive Forces act with a contrary Direction, they will revolve about each other, if in the ſame, they will mutually attract each other, and unite and cloſe together, which is the moſt likely, as they all Gravitate to the Earth, and therefore have the ſame Contractive Force with it.

Quantities of the Contractive Forces.

The Greater Quantity of any Contractive Force there is, the Force will by ſo much be Increas'd; a Ball of Snow has a Greater Contractive Force, and is Colder than a ſmall Plume, Flower, or Iceele of it; a large Heap or Congeries has a Greater Contractive Force than a Ball of it; a Mountain or Ocean of Ice has a Greater Contractive Force than a little Chryſtal of it; a Globe of Gold, Lead, Iron, *&c.* of 10, 20, or 100, or 1000 Inches Diameter has a Greater Contractive Force than one of 2, 3, or of 5; The Earth has a Greater Contractive Force than any Greater or Leſs Portion of it; and every Planet has a Greater Contractive Force than it's Half or any other Part.

Diſtances of the Contractive Forces.

As to the Diſtances of theſe Contractive Forces, the Forces are Greater the Nearer they are from the Centers of their Action; the Nearer the Moon comes to the Earth, the Greater Effects it has in Freezing Waters into Ice, or Raiſing them into Tides, ſo that if the Earth was ſome Miles nearer to it, it wou'd be Cover'd with an univerſal Froſt, and the whole Seas drawn into Vaſt and Stupendous Mountains from the Boſom of the Ocean; if we touch Ice or Snow, it is Colder than if we are at ſome Diſtance from it, if we are in the Coldeſt Countries, as in *Greenland*, *Norway*, or *Ruſſia*, we are more ſenſible of it's Effects, than if we are in more Diſtant Regions from them; the Nearer any Planets approach to each other, the Greater is their Force of Contraction, that is, they more obſtinately and ſtrongly maintain their own Particular Forces of Drawing and Attracting Bodies to their own Centers, thus alſo the Nearer any Gravitating Body is to the Earth, it is more forcibly drawn and impell'd by it.

Inſtance 2. Air, Water, Earth, Stones, Minerals, Metals.

Air, which is the fartheſt from the Center of the Earth's Contraction, has a leſs Contractive Force than Water or Earth; Water and Earth, which are upon the Surface, than Marl, Clay, Stones, Minerals, and Metals, which lie within the Bowels of it; and ſtill Nearer to the Center, there may be a Matter for all we know, which is ſtill Denſer, Groſſer, and more Impenetrable than any we meet with here.

Inſtance 3. Vegetation.

The Contractive Force of Plants and Trees, which are farther from the Center, is leſs than that of Earth or Water, by which Wood becomes Lighter than it, 'tis leſs in the Leaves than in the Boughs, in the Branches than in the Trunk, and in the Trunk than at the Root the Particular Center of ſuch Contractive Forces.

It may be farther obſerv'd, in Reſpect of Vegetation, that the Moon likewiſe in all Probability, as well as the Sun, has here it's Influence, the Sun by it's Expanſive, and the Moon by it's Contractive Force, both Conſpiring as to raiſe the Tides, ſo to draw forth Plants and Trees from the Earth; From whence it will follow, that as the Fluxes in ſuch certain Circumſtances are Elevated only to a determin'd Height, ſo Plants and Trees, according to their ſeveral peculiar Expanſive and Contractive Forces, acting from and towards the Root and aſſiſted by the Expanſive and Contractive of the Sun and Moon, have their ſtinted Growth, and do not riſe in Infinitum, but agreeably to the Strength and Proportion of the Acting Forces; and as the

Sun and Moon are the Two Grand Sources of the Expanſive and Contractive, ſo ſuitably we find all Earthly Bodies, under whoſe Influences they are, are compounded of Them.

Inſtance 4.
OdorousBodies.

ODOROUS Bodies have alſo a Contractive Force, by which they are hinder'd from being diſſipated by their Expanſive, and which therefore only Exert themſelves in one continu'd Pulſe upon the Ethereal or Airy Plenum, which ſurrounds them; This Contractive Force is the Greateſt at the Center, and Leſs in any Removals from it, which is the Reaſon, that the Flowers and Leaves of Trees Smell more than the Branches, the Stock, or the Root.

Inſtance 5.
Sound.

BODIES likewiſe, which are Sonorous, have a Contractive Force, which is the Greateſt at the Center, and Leſs at various Diſtances from it, thus the String of a Harp or a Violin, is more Sonorous in the Middle of it than in the Center of it's Contraction or Tenſion; A Bell is more Sonorous towards the Extremities than in the Center of it's Suſpenſion or Contraction.

Inſtance 6.
Colour.

COLOUR'D Bodies have a Contractive Force, by which their Parts are kept and detain'd together, and the Nearer thoſe Parts are to each other, their Contractive Force is the Greater, all other Things being Equal, and the more firmly they cohere.

Inſtance 7.
The Animal Syſtem.

LASTLY, The Animal Syſtem has a Contractive, as well as an Expanſive Force belonging to it, as is Evident from the Syſtole and Diaſtole of the Heart, from the Pulſe or Contraction and Dilatation of the Arteries, and from the Expanſion and Contraction of the Muſcles. The Source of Expanſion ſeems to be that of the Mind, by which the Body is transfer'd from one Place to another, and all it's Actions are perform'd according to the Direction of the Will, and the Source of Contraction that of Matter, in Reſpect of the Mind; and as the Expanſive and Contractive Forces are united, according to what we have ſhewn, in all Material Beings, ſo the Expanſive Force of the Mind, may be united with the Contractive of Matter; but yet, as the Expanſive Force of the Sun is perfectly Contrary to and Different from the Contractive of the Earth, or the Moon, or the Planets, ſo likewiſe the Nature of the Mind, which is Expanſive, is entirely Different from that of Matter, which is Contractive; and laſtly, as the Expanſive Force, as that of the Sun, can ſubſiſt of it ſelf without the Contractive, ſo likewiſe can the Mind, which is of an Expanſive Nature, without Matter, tho' at preſent it is united to it; which, if duly attended to, will give an Account, how the Mind may be united as it really is to the Body, and how it may yet Exiſt in a State of Separation from it.

From whence proceeds the Difference and Variety of the Expanſive and Contractive Forces.

§. 43. IF it be now Inquir'd, what is the Cauſe of theſe Expanſive and Contractive Forces, of which all Material Nature conſiſts, and what is the Reaſon of the Difference and Variety of them? The laſt Queſtion may be eaſily anſwer'd, that they proceed from the Different and Various Combinations of their Forces, Quantities, and Diſtances alledg'd in the Preſent Theorem; Thus, ſuppoſing the Sun to have it's particular Expanſive Force, the Moon to have it's Particular Contractive, and the Earth another Contractive peculiar to it ſelf, and contrary to the Former, and each of them their ſeveral determin'd and certain Quantities and Diſtances, we may eaſily conceive what Effects will ariſe from Differently Combining them. Let us firſt take the Sun and it's Expanſive Force, at an Infinitely ſmall Diſtance from it, the Intrinſick Force, by which it Heats, Diſſipates, and Repels, conſider'd together with the vaſt Quantity of it, will be Prodigious and Immenſe, ſo that if any Planet were to approach near it, it wou'd not only Heat and Diſſipate the Parts of it to an Inexpreſſible Degree, but wou'd Repel it with the utmoſt Force and Violence; and which may be a Reaſon, why the Planets move with a Greater Velocity in their Periheliums than in their Apheliums, as their Contractive Forces may be another, which have been before Explain'd.

THIS vaſt Expanſive Force to us, who are in the Northern Climates, at the Diſtance of our Earth and in our Tropick, Heats, and in the Winter Solſtice only Warms, and to thoſe, who are under the Æquinox, it Scorches and Burns, and it's Diſſipating and Repulſive Power is accordingly leſs or more Forcible, by which it drives us into Shades, raiſes Water into Vapours, and propels all Things from it, which are too Weak for it's Action; and a Million of Intermediate Degrees of this Expanſive Force lie at Various Diſtances betwixt us and the Sun, as here it is Different in Different Climates, that is, at Different Diſtances from it; It is alſo vary'd at the ſame Diſtance, by taking Different Proportions and Quantities of it; It is diminiſh'd by being Reflected and Diſſipated, and increas'd by being Collected in Greater Plenty to a Focus, the Firſt ariſing from the Superiority of the Contractive Force in the Glaſs, above that of the Expanſive in the Rays, and the Laſt from the Superiority of the Expanſive in the Rays, above the Contractive in the Glaſs. This Expanſive Force mixing in Various Proportions with Earthly Bodies, or which have a Contractive Force, cauſes Different Effects, and in all of them has a Warming, Diſſipating, and Repulſive Quality; Where a great Proportion of it is join'd with a light and leſs Contractive Force, as with Wood or Hay, or any other Combuſtible Matter, it produces Fire and Flame, which has Heat by it's Warming of us, has a Force of Diſſipation by it's throwing Fuel into Smoke, and Water into Vapours, and Metals into Fuſion, and has a Repulſive Power, by it's Power of Diſſipation, as alſo by making us retire from it, when it's Action is too Violent, and by Raiſing Liquors into Waves and Ebullitions in the Boiling of them; The ſame Expanſive Force mixing ſtill in leſs Proportions with Bodies, which have a like Contractive Force, or in like Proportions with Bodies, which have a Greater, do's not Riſe into Flame, but Sinks into Taſt, Smell, Colour, Sound, Vegetation, *&c.* which all, as has been ſhewn, have a Degree of the Expanſive, by which they Exert themſelves againſt the Contractive, and Endeavour to Diſſipate and Repel it's Force; This conſtant Conatus of the Expanſive ſtrikes as conſtantly upon the Medium, which ſurrounds it, by which means thoſe Senſations are convey'd to us, which alſo have a kind of Life and Warmth in them by the Vivacity and Chearfulneſs which they impart to us, and is another Property of the Expanſive.

As we have ſhewn therefore, that the Expanſive Force of the Sun may be Infinitely diverſify'd, by it's Quantity and Diſtance, and by the Nature of the Contractive with which it Mixes, ſo likewiſe it wou'd be eaſy to Explain how the Contractive Forces of the Moon and Earth, which are Contrary in themſelves to each other, by their Various Diſtances and Quantities, may compound Variety of Solid, Cold, Heavy, and Contractive Bodies, which, mingling and blending their Forces with the Expanſive ones of the Sun, are the Occaſion of the numberleſs Appearances, which occur to us in this Earth or Planet; in which we may juſtly ſuppoſe there is no ſuch Thing as a Central Fire, as has been Imagin'd by ſome, but rather that the Nearer we come to the Center, the Solid and Contractive Force will be the Greater, without any Expanſive at all, which we Originally and Principally Derive from the Sun, and which it is not unlikely is the Central Fire, meant and intended by Philoſophers, as being the Center, tho' not of the Earth, yet of the Earth's Syſtem.

The Expanſive and Contractive Forces themſelves cannot be Self-exiſtent, but are deriv'd from an Infinite and All-wiſe Agent.

§. 44. THUS we ſay it is eaſy to Anſwer the ſecond Queſtion, *viz.* from whence proceeds the Variety of Expanſive and Contractive Forces obſervable in Nature, and perhaps this is as far, as it is poſſible for Human Minds to reach in Philoſophy, but as to the Firſt, what is the Cauſe of them, we can ſay no more than that they muſt be either Self-Exiſting, and no Cauſe can be aſſign'd of them, or elſe, that they muſt be deriv'd from the Will and Pleaſure of God; To imagine or think the Firſt is Abſurd, for whatever Exiſts of it ſelf, will have a neceſſary, certain, and unvary'd Principle of it's Exiſting, becauſe there is nothing, which can change the Nature of a Neceſſary-Exiſtence, but here are a Thouſand and a Million of Expanſive Forces, Different in themſelves, and Acting contrary to each other, and from Different Centers; for what we have alledg'd of the Sun will be equally Applicable to the ſeveral fixt Stars in the Univerſe, which may be juſtly deem'd to be ſo many Suns, Acting with Various Expanſive Forces, Intrinſically Different in themſelves, and of Various Quantities and Magnitudes, and which Actuate and Inform ſo many Syſtems round them; Beſides which, the Contractive Forces of the Earth, the Moon, and Planets, which Conſtitute this Solar Syſtem are Forces contrary to the Expanſive, and Act with a contrary Direction amongſt one another, and are Intrinſically Different in the Nature and Degree of them; Add to this, that the Contractive Forces of Planets, which belong to a Million of other Solar Syſtems diſper'd thro' the Grand and Univerſal Expanſe, and which lie ſo Deep in it as perfectly to eſcape our Sight and Obſervation, may be Infinitely Different from thoſe which appertain to This, which Variety of Forces cannot agree with one certain Self-Exiſting Principle of all their Actions, unleſs a Directing and Intelligent one. Moreover, where we obſerve Expanſive and Contractive Forces Acting all Manner of Ways, and in all Kinds of Direction, and which are ſo adjuſted as to produce Regular and Uniform Syſtems, we always find an Intelligent and Thinking Being annext to them, or is the Cauſe of them, thus it is in the Human and Animal Frame, and thus it is in thoſe Various Pieces of Mechaniſm and Art, contriv'd by the Invention and Sagacity of Men; when therefore we perceive the ſame in Nature, excepting in a more Infinite Degree, it is Reaſonable and Juſt to ſuppoſe, that there is an Infinite Mind affixt to it, and that it Proportions all the Actions and Forces of it, ſo as to produce thoſe Regular and Orderly Syſtems we ſo conſtantly behold; If a Balance was hung up, and Different Portions of Matter plac'd in it, by which there wou'd be an Equal Poiſe of them, it wou'd be Madneſs not to believe, and think this was done by ſome Intelligent Being; And is it poſſible for us, when we ſee whole Worlds, and their Various Forces, and the Quantities of them, Calculated with that Exactneſs, and plac'd at ſuch Diſtances, which ſhall Conſerve the Order, Poiſe, and Balance of them, ſhall Perpetuate their Revolutions for Ages together, and be the Occaſion of the Numberleſs Productions of Metals, Plants, and Trees, and the other Phænomenons of Material Beings, not to acknowledge the All-wiſe and Intelligent Contriver, Orderer, and Diſpoſer of them?

This to me is the chief and only Proof of the Being of a God, to wit, the Works of Nature; and when we have Found what Nature is, we are then the beſt Capable of Judging of the Author of it, not by Metaphyſical Notions and Fancies of our own Inventing, but by conſidering what really Exiſts, and from thence Inferring and Collecting the neceſſary Cauſe of ſuch an Exiſtence; We have in Conſequence of this ſhewn, that all Nature conſiſts of an Infinite Number of Actions Different in their Forces, and Contrary in their Directions, that ſuch cannot be Self-Exiſtent, and therefore muſt neceſſarily lead us to ſome Agent; that theſe Actions are Infinite, and Infinitely vary'd, that they are Extended thro' Infinite Space, and therefore this Agent muſt be Infinite and Almighty; that they are adjuſted and diſpos'd according to the Exacteſt Calculations of their Intrinſick Force, their Quantities and their Diſtance, and therefore this Infinite and Almighty Agent muſt be All-wiſe and Infinitely Intelligent; that theſe Calculations are made to produce that Exact, Beautiful, and Excellent Order and Diſpoſition of Things we at Preſent ſee, and for the Uſe and Service of his Creatures, and therefore he muſt be Infinitely Juſt and Good; From hence alſo, we are Inform'd of the Way and Manner, by which all Matter and the whole World was Created, and may be Annihilated, for ſince all Matter and the whole World conſiſts of certain Actions or Forces, it is eaſy to Comprehend how an Infinite Agent, by the Energy of his Power, may produce ſuch Forces into Being, and when he Surceaſes his Action, may Reduce them to Nothing.

Tho' all True Philoſophy muſt at length have Recourſe to a Supreme Agent and Director, yet the Principles we have advanc'd are the moſt Extenſive, which have been hitherto propos'd in any Syſtems of it, and beyond which no Philoſophy can go.

Sir Iſ. Newt. Queries, at the End of his Theory of Light and Colours.

§. 45. If any one ſhall object againſt this Philoſophy, that we are at length oblig'd to recur to the Will and Pleaſure of the Infinite and All-wiſe Diſpoſer for a Solution of all, we ſhall only in Anſwer to ſuch an Objection ſhew the Difference, which lies betwixt what others have propos'd in Philoſophy, and what we have done in this, and demonſtrate that we have advanc'd ſeveral Steps beyond any of them, and have more Effectually prov'd that the ultimate Principle of all is God. As to what is call'd the Corpuſcularian, it is known, that after, as we have ſhewn, it had given a Lame and Imperfect Account of the Accidental Properties of Matter, as Heat, Cold, Colour, Sound, Taſt, Smell, *&c.* upon the Suppoſition of it's being Similar and Homogeneous, it did not pretend to Explain the Primary Qualities of it, Extenſion, Solidity, Impenetrability, and the like, which it own'd were Properties not to be medled with, they conſtituted the firſt Eſſence of Matter, and which was no farther to be conſider'd than as ſuch, which Almighty God had Created, or which Exiſted ſo of it ſelf without any other Cauſe; and yet we have gone farther, and given a Reaſon and Explanation of thoſe Properties.

As to the Preſent Mechanical, it reſolves all ultimately into Gravitation, but did not at Firſt offer at any Solution of Gravitation it ſelf, but either ſuppos'd it was Inherent in Matter or Impreſs'd by God, and left it to the Piety and Reaſon of it's

Followers to conclude the one or the other, and afterwards in it's Queries, at the End of the Light and Colours, when it had Invented an Imaginary and Elaſtick Fluid to account for that Force, it was oblig'd to ſtop there, and we were as much to ſeek from whence that Elaſticity was deriv'd, as the Gravitation aſſerted before, and all that cou'd be Inſer'd from this New Addition to that Philoſophy, was only this, that it appear'd to affirm a Plenum, which it had formerly deny'd, and in ſo many Terms recanted it's Demonſtration of a Vacuum; and yet notwithſtanding this, we have endeavour'd to give a Reaſon of Gravitation and of Elaſticity both, the laſt Proceeding from an Expanſive or Repulſive, and the firſt from a Contractive Force, whoſe Laws and Proportions of Action we have aſſign'd, and by them ſhewn how Nature may be in a great Meaſure accounted for; but if after this we wou'd ſtill proceed farther without a Supreme and Superintending Agent, we ſhall be miſtaken; and it will not be poſſible, I believe I may foretel it, for all the Great Wits and Genius's in the Preſent or any Future Ages, to extend their Enquiries beyond theſe Two Principles of Expanſion and Contraction; there we muſt Stand, and there we muſt Acknowledge, that as they cannot ſubſiſt of themſelves without an Agent, ſo we muſt Confeſs, that Almighty God is that Agent.

A True Philoſophy do's not Weaken but Confirm the Evidences, which we have of the Chriſtian Religion, and is an Atteſtation to the Truth of the Rewards and Puniſhments which it propoſes.

§. 46. And ſince we are Enter'd into the Aſſertion of Religion, which was one Deſign and Intention of this Philoſophy, as the other was to Enquire into what was Truth and Reaſon, I ſhall here add, that in Reſpect of the Happineſs promis'd to the Good and Vertuous in another Life, and the Torments and Miſeries Threaten'd to the Wicked and the Vicious, we have Nothing in Nature to contradict or to weaken thoſe Perſuaſions, but on the Contrary have abundant Arguments to confirm them. Everlaſting Fire is Threaten'd to a Diſobedience to Religion, if therefore, we cou'd find and obſerve no ſuch Thing in Nature, it might make us leſs Apprehenſive of the Threat, but when we perceive not only that Immenſe Fire, the Sun, but a Thouſand and a Million of others, as we may juſtly believe in the vaſt Expanſe of the Univerſe, ready Lighted up, and Prepar'd for what uſe the Infinite and Great Creator ſhall pleaſe to aſſign them, it wou'd make any Conſiderate Man very careful how he provok'd the Diſpleaſure of a Being who Created all of them, and for more Intents and Purpoſes than ſome Fond and Fooliſh Men may be apt to Imagine; it wou'd make him at leaſt Inquire with Seriouſneſs, whether that Chriſtian Religion, which is ſaid to be a Revelation from him, is, or is not ſo; and if it is, as there are a Thouſand Arguments for it's being ſo, it wou'd make him very Cautious how he offends againſt it, either in Reſpect of it's Doctrines or it's Morals.

On the other Hand, Everlaſting Happineſs is promis'd to the Believing and to the Obedient, and here we may likewiſe ſay, if ſuch a Thing appear'd to be Impoſſible in Nature, we might reject the offer perhaps with Indignation, and look upon it as a Paradice propos'd to the Fooliſh and the Credulous, that is, if there were not ſufficient Reaſons to aſſure us of the Truth of Chriſtianity; But when in Conjunction with thoſe Reaſons, we find in Nature nothing but what is agreeable to, and juſtifies ſuch Propoſals of Happineſs to us, this likewiſe wou'd make us Careful, how we Deſpiſe and Contemn ſuch a Religion.

We obſerve in our own Earth, that we are here Mortal, but tho' we are ſo, we Experience a great Deal of Pleaſure and Satisfaction, whilſt we Live, from that Diſpoſition of the Sun and Moon, which obtains with us, and from the Various Productions, which they Cauſe in Nature, of Plants and Herbs and Trees, of Minerals and Metals, and the other Material Beings, which ſurround us. Suppoſing now, as in *Jupiter* and *Saturn*, ſeveral Moons were to revolve about our Earth, with Various Situations and Diſpoſitions, wou'd it not Increaſe our Pleaſure, by the wonderful Variety of ſuch Luminaries, and their Different Forces and Situations to us? And as the Conſtitution of Things is entirely Different in other Planets from that of our own, why may we not think, that there may be Rational and Intelligent Agents in them, whoſe Bodies are of a Different Make and Conſtitution from ours, and who live ſeveral Years or Ages longer than we do? Eſpecially, when in our own Planet, we are fully Inform'd, that in the Times before the Deluge, and preſently after, Men were more Gigantick in their Stature, and more Strong and Laſting in their Stamen than what was Experienc'd in after Times, or is in the Preſent; The Reaſon of which can be no other than the Elevation of the Antediluvian

Earth towards the Sun and Moon above our own, before the falling of the Cruſt or Surface of it, by which means the Expanſive Force of the one, and the Contractive of the other, wou'd have a Greater Influence and Power, ſo as to raiſe both the Animal and Vegetable World to a Greater Height than what we at preſent find, and as their Forces were Stronger, their Effects wou'd be more Permanent and Laſting.

Let us now paſs to other Syſtems, ſuch, which lie the Deepeſt in the vaſt Expanſe and the Remoteſt from us, and of which we have no Knowledge; Who yet with all his Reaſon and Philoſophy can ſay, that there may not be ſuch contriv'd by the Infinite Wiſdom and Goodneſs of God, which ſhall be fitted and adapted to glorify'd Spirits and Bodies, by which their Pleaſure ſhall be Immenſe, and their Duration Eternal, and which he has deſtin'd to be the Seats and Manſions of the Bleſſed? And Who can contradict, what our Saviour affirms, that in his Father's Houſe, in the Great and Spacious Palace of the Univerſe, there are many of them? Let us Imagine then this farther, that as there are even in our Syſtem Reaſons to think, that there may be a Thouſand Occaſions of Delight to us, more than what we at preſent Experience, ſo in the Innumerable Syſtems, which there are in the Great Expanſe, we may find, when we are Immortal, and when the Expanſive Force of our Souls is ſeparated from that of the Contractive of the Body, an Incredible and Everlaſting Pleaſure, by Removing to and Contemplating every Syſtem, according to the Direction and Pleaſure of the Mind. This I only mention to ſhew, that there is nothing in Nature, which Contradicts our Religion, but which ſtrongly Enforces it, and that therefore our firſt Wiſdom is to be Good and Real Chriſtians, and in the next Place to underſtand as much of Reaſon and Philoſophy, as the Preſent Attainments in it or our own Studies will allow us to do.

CHAP. VI.

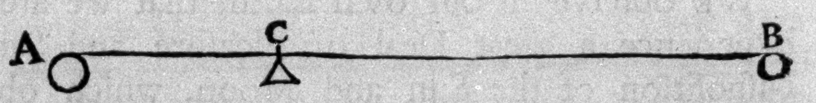
Concerning the Mutual Concourſe of Bodies, Hard, Soft, or Elaſtick.

Propoſition the Firſt Explain'd, Relating to the Progreſs or Quieſcence of the Center of Gravity. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 13. Theorem 20. Sir Iſ. Newt. Princip. Leg. Corol. 4.

§. 1. We ſhall now Proceed to the Doctrine of the Mutual Concourſe of Bodies, whether Hard, Soft, or Elaſtick, by Explaining the Whole of it, as propos'd by the Preſent Mechanical Philoſophers, and then Giving a particular Anſwer to it.

The Firſt Propoſition therefore, in Order to furniſh us with a Solution of theſe Matters, is, That if Two or More Bodies are carry'd with an Equable Motion to the ſame or contrary Sides or Parts, their Common Center of Gravity before their Mutual Occourſe will be either Quieſcent, or will be mov'd Uniformly in Directum.

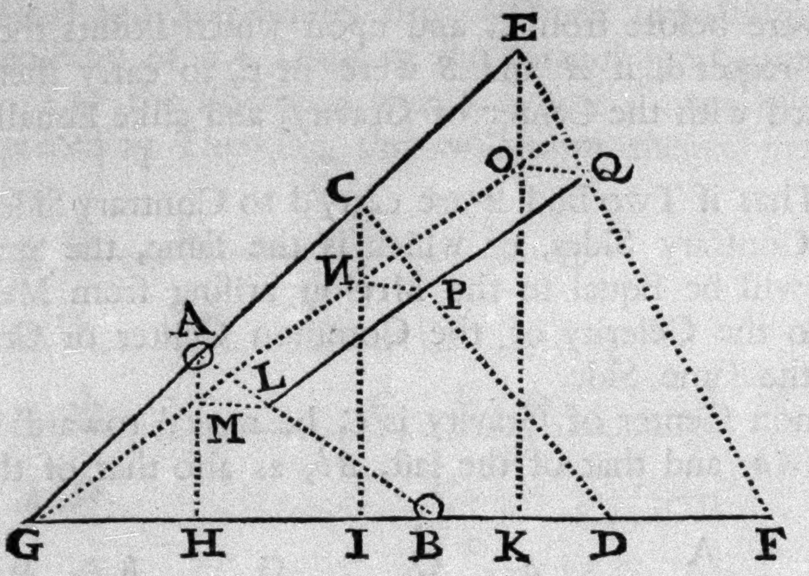
Caſ. 1. Supposing Two Bodies are mov'd to Contrary Parts, that is, let A and B be mov'd towards C, or from C, ſince the Nature of the Center of Gravity is, that $A . B :: BC . AC$, or that the Bodies, in their Weights, ſhou'd be Reciprocal to their Diſtances from their Center C, upon which they are Pois'd, and are in an Equal Balance with each other, it follows, if A and B are mov'd towards C, or from it, ſo as to preſerve the ſame Reciprocal Proportion of their Diſtances from C to their Matter, that they will ſtill be in an Æquilibrium, which will be Effected, if their Velocities are as BC to AC, or as A to B, that is, if their Motions are Equal, for if A the Matter $. B$ the Matter $::$ BC the Velocity $. AC$ the Velocity, the Motion $A \times AC$ is $= B \times BC$; and conſequently, A and B may be carry'd from C in Infinitum, or meet in C if carry'd towards it, whilſt the Center of Gravity will be always Quieſcent in C.



Caſ. 2. If now the Two Bodies A and B are carry'd to the ſame Side with a like Motion as before, or to Contrary Sides with an unequal one, their common Center of Gravity will be mov'd in Directum, becauſe the Velocities AC, CB will be Reciprocal to the Quantities of Matter A and B, and thoſe Velocities are as the Diſtances from the Center of Gravity; as therefore A and B move the ſame Way, it is neceſſary that C ſhou'd do ſo too, that the Proportion of the Velocities and Diſtances from C may be preſerv'd Reciprocal to A and B.

On the other Hand, if A and B are carry'd to Contrary Sides with an Unequal Motion, ſince the Velocities are not Reciprocal to the Quantities of Matter A and B, nor the Diſtances from the Center of Gravity AC, BC, the Bodies A and B will be no longer in an Equal Poiſe upon C, and which muſt therefore change it's Situation to make them ſo; that is, C muſt be remov'd to ſome other Point in the Line AB, where $A.B::BC.AC$.

Caſ. 3. Supposing the Bodies A and B move in Two Lines AC and BD inclin'd to each other, and that in Equal Times they ſeparately perform Equal Spaces, ſo that AC is $=CE$, and $BD=DF$, we ſay, that the Center of Gravity will be mov'd uniformly in the Line LQ, and that LP will be Equal to PQ; Let the preſent Figure and Conſtruction be Imagin'd as here Deſcrib'd, that is, let $AC.BD::AG.GH$, draw the Line AH, and from C and E, CI and EK Parallel to it; Join alſo A and B, C and D, E and F, and to the Line BD let ML, NP, OQ be likewiſe Parallel, and in the firſt Situation of A and B, let L be the Center of Gravity, and from the Point G thro' M draw the Right Line GO.



First, P and Q in the Line LQ will upon the Motion of A to C and E, and of B to D and F, be the Centers of Gravity, for by Elem. 6. Prop. 4. Corol. 2. Edit. Tacquet, $AM.MH::CN.NI::EO.OK$; but by Prop. 2. Elem. 6. $AM.MH::AL.LB$, and $CN.NI::CP.PD$, and $EO.OK::EQ.QF$, therefore $AL.LB::CP.PD::EQ.QF$.

Second, $LP=PQ$, for by the Conſtruction $AC.BD::AG.GH$, by Elem. 6. Prop. 2. $::AC.HI$, therefore $BD=HI$, add IB to both, and $ID=HB$; alſo by the Conſtruction, $CE.DF::AG.GH$, by Elem. 6. Prop. 2. $::CE.IK$, therefore $DF=IK$, add KD to both, and $KF=ID$, that is, the Baſes of the Three Triangles BAH, DCI, FEK are Equal; But by Elem. 6. Prop. 4. $AM.AH::ML.HB::CN.CI::NP.ID$, ſince therefore $HB=ID$, it will follow that $ML=NP$, and by the ſame way of Reaſoning $NP=OQ$; farther by Elem. 6. Prop. 2. Corol, $AC.CE::MN.NO$, But $AC=CE$, therefore $MN=NO$; and conſequently, ſince a Line drawn from L thro' P and Q will be Parallel to MO, becauſe ML, NP, OQ are Parallel and Equal, LP will be $=$ to PQ, ſince MN and NO are Equal; and what has been Demonſtrated of P and Q, may be ſhewn of any other Points in LQ.

Caſ. 4. If the Bodies are not mov'd in the ſame Plane, but in Different ones, their Progreſſes, as well as that of the Center of Gravity, are to be reduc'd to the ſame Plane, by letting down Perpendiculars to it from each Point of their Progreſs, by which means this Caſe will be brought under the Former, and the Demonſtration will be the ſame.

Caſ. 5. Supposing now there are more Bodies than Two, by placing the Center of Gravity of the Two Bodies ſo, as the Diſtance of it from a New Center of Gravity, ſhall be to the Diſtance of a Third Body from the ſame Center, as the Third Body is to the Sum of the Two, all Things will be in the ſame Circumſtances as before, excepting that the Two Bodies, poiſ'd upon their Center of Gravity, are now conſider'd as one; and the like will obtain, if we ſuppoſe Three, Four, Five, or a Hundred Bodies all Balanc'd upon a Center of Gravity, for in that Caſe, they may be conſider'd, in their Sum and their Weight, as one Body only.

Earth towards the Sun and Moon above our own, before the falling of the Cruſt or Surface of it, by which means the Expanſive Force of the one, and the Contractive of the other, wou'd have a Greater Influence and Power, ſo as to raiſe both the Animal and Vegetable World to a Greater Height than what we at preſent find, and as their Forces were Stronger, their Effects wou'd be more Permanent and Laſting.

Let us now paſs to other Syſtems, ſuch, which lie the Deepeſt in the vaſt Expanſe and the Remoteſt from us, and of which we have no Knowledge; Who yet with all his Reaſon and Philoſophy can ſay, that there may not be ſuch contriv'd by the Infinite Wiſdom and Goodneſs of God, which ſhall be fitted and adapted to glorify'd Spirits and Bodies, by which their Pleaſure ſhall be Immenſe, and their Duration Eternal, and which he has deſtin'd to be the Seats and Manſions of the Bleſſed? And Who can contradict, what our Saviour affirms, that in his Father's Houſe, in the Great and Spacious Palace of the Univerſe, there are many of them? Let us Imagine then this farther, that as there are even in our Syſtem Reaſons to think, that there may be a Thouſand Occaſions of Delight to us, more than what we at preſent Experience, ſo in the Innumerable Syſtems, which there are in the Great Expanſe, we may find, when we are Immortal, and when the Expanſive Force of our Souls is ſeparated from that of the Contractive of the Body, an Incredible and Everlaſting Pleaſure, by Removing to and Contemplating every Syſtem, according to the Direction and Pleaſure of the Mind. This I only mention to ſhew, that there is nothing in Nature, which Contradicts our Religion, but which ſtrongly Enforces it, and that therefore our firſt Wiſdom is to be Good and Real Chriſtians, and in the next Place to underſtand as much of Reaſon and Philoſophy, as the Preſent Attainments in it or our own Studies will allow us to do.

CHAP. VI.

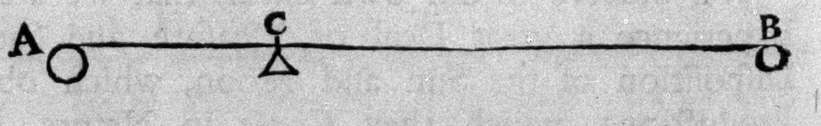
Concerning the Mutual Concourſe of Bodies, Hard, Soft, or Elaſtick.

Propoſition the Firſt Explain'd, Relating to the Progreſs or Quieſcence of the Center of Gravity. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 13. Theorem 20. Sir Iſ. Newt. Princip. Leg. Corol. 4.

§. 1. WE ſhall now Proceed to the Doctrine of the Mutual Concourſe of Bodies, whether Hard, Soft, or Elaſtick, by Explaining the Whole of it, as propos'd by the Preſent Mechanical Philoſophers, and then Giving a particular Anſwer to it.

The Firſt Propoſition therefore, in Order to furniſh us with a Solution of theſe Matters, is, That if Two or More Bodies are carry'd with an Equable Motion to the ſame or contrary Sides or Parts, their Common Center of Gravity before their Mutual Occourſe will be either Quieſcent, or will be mov'd Uniformly in Directum.

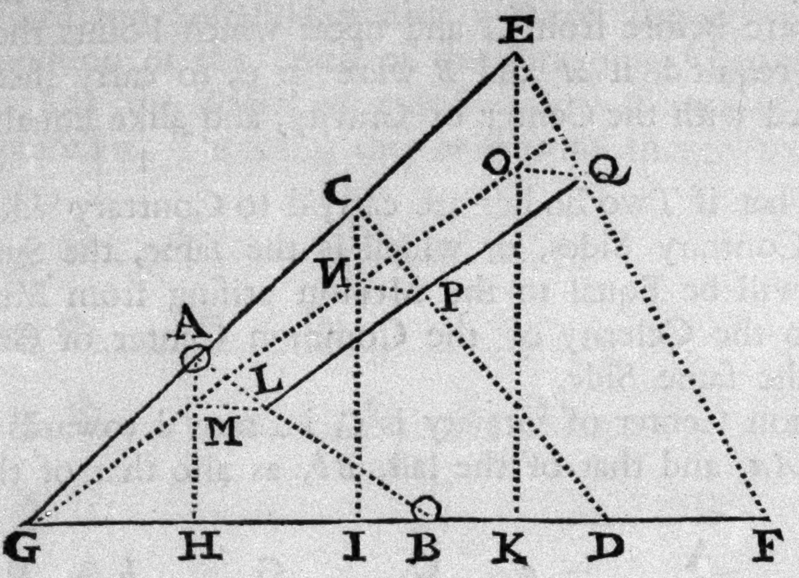
Caſ. 1. Supposing Two Bodies are mov'd to Contrary Parts, that is, let A and B be mov'd towards C, or from C, ſince the Nature of the Center of Gravity is, that $A.B::BC.AC$, or that the Bodies, in their Weights, ſhou'd be Reciprocal to their Diſtances from their Center C, upon which they are Pois'd, and are in an Equal Balance with each other, it follows, if A and B are mov'd towards C, or from it, ſo as to preſerve the ſame Reciprocal Proportion of their Diſtances from C to their Matter, that they will ſtill be in an Æquilibrium, which will be Effected, if their Velocities are as BC to AC, or as A to B, that is, if their Motions are Equal, for if A the Matter $.B$ the Matter $::BC$ the Velocity $.AC$ the Velocity, the Motion $A \times AC$ is $= B \times BC$; and conſequently, A and B may be carry'd from C in Infinitum, or meet in C if carry'd towards it, whilſt the Center of Gravity will be always Quieſcent in C.



Caſ. 2. If now the Two Bodies A and B are carry'd to the ſame Side with a like Motion as before, or to Contrary Sides with an unequal one, their common Center of Gravity will be mov'd in Directum, becauſe the Velocities AC, CB will be Reciprocal to the Quantities of Matter A and B, and thoſe Velocities are as the Diſtances from the Center of Gravity; as therefore A and B move the ſame Way, it is neceſſary that *C* ſhou'd do ſo too, that the Proportion of the Velocities and Diſtances from *C* may be preſerv'd Reciprocal to *A* and *B*.

On the other Hand, if *A* and *B* are carry'd to Contrary Sides with an Unequal Motion, ſince the Velocities are not Reciprocal to the Quantities of Matter *A* and *B*, nor the Diſtances from the Center of Gravity *AC*, *BC*, the Bodies *A* and *B* will be no longer in an Equal Poiſe upon *C*, and which muſt therefore change it's Situation to make them ſo; that is, *C* muſt be remov'd to ſome other Point in the Line *AB*, where *A.B*::*BC.AC*.

Caſ. 3. Supposing the Bodies *A* and *B* move in Two Lines *AC* and *BD* inclin'd to each other, and that in Equal Times they ſeparately perform Equal Spaces, ſo that *AC* is = *CE*, and *BD* = *DF*, we ſay, that the Center of Gravity will be mov'd uniformly in the Line *LQ*, and that *LP* will be Equal to *PQ*; Let the preſent Figure and Conſtruction be Imagin'd as here Deſcrib'd, that is, let *AC.BD*::*AG.GH*, draw the Line *AH*, and from *C* and *E*, *CI* and *EK* Parallel to it; Join alſo *A* and *B*, *C* and *D*, *E* and *F*, and to the Line *BD* let *ML*, *NP*, *OQ* be likewiſe Parallel, and in the firſt Situation of *A* and *B*, let *L* be the Center of Gravity, and from the Point *G* thro' *M* draw the Right Line *GO*.



First, *P* and *Q* in the Line *LQ* will upon the Motion of *A* to *C* and *E*, and of *B* to *D* and *F*, be the Centers of Gravity, for by Elem. 6. Prop. 4. Corol. 2. Edit. Tacquet, *AM.MH*::*CN.NI*::*EO.OK*; but by Prop. 2. Elem. 6. *AM.MH*::*AL.LB*, and *CN.NI*::*CP.PD*, and *EO.OK*::*EQ.QF*, therefore *AL.LB*::*CP.PD*::*EQ.QF*.

Second, *LP*=*PQ*, for by the Conſtruction *AC.BD*::*AG.GH*, by Elem. 6. Prop. 2. ::*AC.HI*, therefore *BD*=*HI*, add *IB* to both, and *ID*=*HB*; alſo by the Conſtruction, *CE.DF*::*AG.GH*, by Elem. 6. Prop. 2. ::*CE.IK*, therefore *DF*=*IK*, add *KD* to both, and *KF*=*ID*, that is, the Baſes of the Three Triangles *BAH*, *DCI*, *FEK* are Equal; But by Elem. 6. Prop. 4. *AM.AH*::*ML.HB*::*CN.CI*::*NP.ID*, ſince therefore *HB*=*ID*, it will follow that *ML*=*NP*, and by the ſame way of Reaſoning *NP*=*OQ*; farther by Elem. 6. Prop. 2. Corol, *AC.CE*::*MN.NO*, But *AC*=*CE*, therefore *MN*=*NO*; and conſequently, ſince a Line drawn from *L* thro' *P* and *Q* will be Parallel to *MO*, becauſe *ML*, *NP*, *OQ* are Parallel and Equal, *LP* will be = to *PQ*, ſince *MN* and *NO* are Equal; and what has been Demonſtrated of *P* and *Q*, may be ſhewn of any other Points in *LQ*.

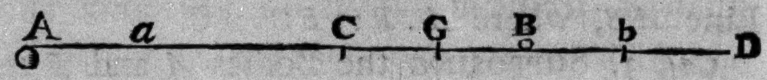
Caſ. 4. If the Bodies are not mov'd in the ſame Plane, but in Different ones, their Progreſſes, as well as that of the Center of Gravity, are to be reduc'd to the ſame Plane, by letting down Perpendiculars to it from each Point of their Progreſs, by which means this Caſe will be brought under the Former, and the Demonſtration will be the ſame.

Caſ. 5. Supposing now there are more Bodies than Two, by placing the Center of Gravity of the Two Bodies ſo, as the Diſtance of it from a New Center of Gravity, ſhall be to the Diſtance of a Third Body from the ſame Center, as the Third Body is to the Sum of the Two, all Things will be in the ſame Circumſtances as before, excepting that the Two Bodies, pois'd upon their Center of Gravity, are now conſider'd as one; and the like will obtain, if we ſuppoſe Three, Four, Five, or a Hundred Bodies all Balanc'd upon a Center of Gravity, for in that Caſe, they may be conſider'd, in their Sum and their Weight, as one Body only.

The Second Propoſition relating to the Motion of Bodies, and their Center of Gravity explain'd. Dr. Keill's Introduct. Lect. 13. Theorem 21.

§. 2. THE Second Propoſition in this Doctrine is, That if Two Bodies, however Equal or Unequal, are carry'd to the ſame Side, with Celerities however Equal or Unequal, the Sum of the Motions in both Bodies will be Equal to the Motion ariſing from Multiplying the Sum of the Bodies into the Celerity of the Common Center of Gravity.

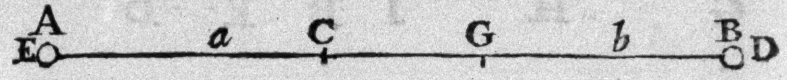
THUS, let *A* and *B*, whoſe Common Center of Gravity is *C*, be mov'd towards *D*, let the Celerity of *A* be *Aa*, That of *B*, *Bb*, and That of the Center of Gravity, *CG*, it is ſaid, that $A \times Aa + B \times Bb$ is $= \overline{A+B} \times CG$; becauſe it muſt be the ſame Thing, and the ſame Moment and Force muſt be requir'd, whilſt *C* moves to *G*, to carry *A* to *a*, and *B* to *b*, where *a* and *b* are at the ſame Diſtance from *G*, as *A* and *B* were before from *C*, and upon which Points they remain Equally Pois'd, as wou'd be requir'd, if *A* and *B* were in *C*, to carry them to *G*, where they are always Connected with the Center of Gravity, and alike Equally Balanc'd upon it.



The Third Propoſition explain'd. Dr. Keill's Introduct. Theorem 22.

§. 3. THE Third Propoſition is, That if Two Bodies are carry'd to Contrary Sides, the Difference of their Motions to Contrary Sides, or which is the ſame, the Sum of their Motions to the ſame Side, will be Equal to the Motion ariſing from Multiplying the Sum of the Bodies into the Celerity of the Common Center of Gravity, by which they are carry'd to the ſame Side.

THUS, let *A* and *B*, whoſe Common Center of Gravity is *C*, be mov'd towards *C*, and let the Celerity of the firſt be *Aa*, and that of the laſt, *Bb*, as alſo that of the Center of Gravity, *CG*, it is ſaid, that $A \times Aa - B \times Bb$, is $= \overline{A+B} \times CG$; becauſe the Difference of their Motions to Contrary Sides, is the ſame as the Sum of their Motions to the ſame Side, which has been before prov'd to be Equal to $\overline{A+B} \times CG$; that is, by the Nature of the Center of Gravity $BC . AC :: bG . aG$, and therefore that Force or Moment, which will carry *A* to *a* and *B* to *b*, whilſt *C* moves to *G*, upon which Points *A* and *B* are Equally Balanc'd, the ſame Force or Moment will carry *A* and *B* in *C*, from thence to *G*, where they are Connected with the Center of Gravity; and from hence it follows, that if the Difference of the Motions to Contrary Sides is Equal to Nothing, that is, if their Motions are Equal, the Center of Gravity is Quieſcent, as is Evident in it ſelf, and from the foregoing Equation, for if $A \times Aa - B \times Bb$ is $= \overline{A+B} \times CG$, and $A \times Aa - B \times Bb$ is $= 0$, $\overline{A+B} \times CG$ will be alſo Equal to 0, and conſequently *CG* Nothing, or *C* will be Quieſcent.



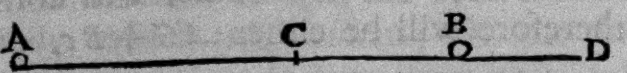
The Fourth Propoſition explain'd. Dr. Keill's Introduct. Theorem 23.

§. 4. THE Fourth Propoſition is, That if any Bodies Impinge or Act upon each other, in any Manner whatſoever, the State and Condition of their Common Center of Gravity, whether it be that of being Quieſcent or Moving uniformly in Directum, is not from thence alter'd. For, by what has been prov'd before in Theorems the 18*th* and 19*th* of this Philoſophy, and which we have afterwards conſider'd and examin'd, if Bodies Impinge upon each other, the Sum of the Motions, before and after Impaction, will be the ſame, and by what has been now Demonſtrated, the Sum of the Motions, before and after Impaction, will be Equal to the Motion ariſing from Multiplying the Sum of the Bodies into the Celerity of the Common Center of Gravity, therefore the Celerity of the Common Center of Gravity will be the ſame before and after Impaction.

The Firſt Propoſition explain'd in Reſpect to the Concourſe of Hard and Soft Bodies. Dr. Keill's Introduct. Lect. 13. Theorem 24.

§. 5. THE next Thing, which this Philoſophy proceeds to, is the Concourſe of Hard or Soft Bodies, the firſt Propoſition of which is, that if a Hard or a Soft Body Impinges directly upon another Hard or Soft Body, whether That, on which the Impaction is made, is Quieſcent or Moves more ſlowly to the ſame Side, or even to Contrary Sides, and ſuppoſing the Motions are Unequal, both the Bodies after Impaction will be mov'd together, and be carry'd along with their Common Center of Gravity.

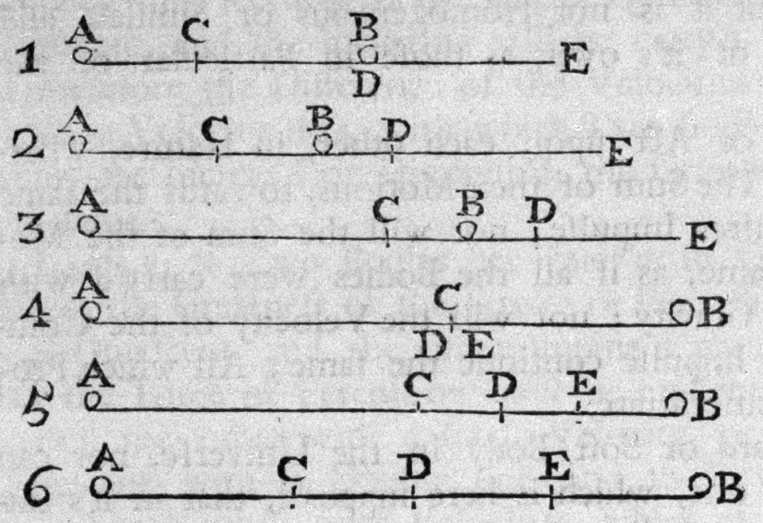
FOR let *A* Impinge upon *B*, according to the Conditions above-mention'd, ſince *B* has no Impediment from any Bodies, which ſurround it, it will, by the Force Impreſs'd from *A*, be mov'd towards the ſame Side, to which the Direction of that Force Tends, and it will be mov'd together, and in Conjunction with *A*, becauſe it cannot move ſlower than *A*, which is behind it, and preſſes it forward, nor can it move faſter than *A*, ſeeing it derives all the Force and Celerity, which it has, entirely from it, there being *ex Hypotheſi* no other Cauſe of this Motion, but the Superior Moment of the Impellent; and as to the Center of Gravity, that muſt Evidently be, where the Bodies are united and move together.



The Second Propoſition explain'd. Dr. Keill's Introduct. Lect. 13. Probl. 2.

§. 6. THE Second Propoſition, in this Doctrine, is to Determine the Motions of Hard and Soft Bodies after a Direct Impaction, which is eaſily done upon the Suppoſition of the Truth of the foregoing Theorem.

LET the Bodies *A* and *B*, whoſe Center of Gravity is *C*, concurr in *D*; by the preceding Theorem, they will from thence move together, and will deſcribe after Impaction a Line $DE=CD=$ to the Velocity of the Center of Gravity before Impaction, becauſe it's Velocity, by what has been already evinc'd, is the ſame before and after Impaction, and therefore the Velocity of *A* before Impaction, will be to it's Velocity after, as AD to DE, and the Velocity of *B* before Impaction to it's Velocity after, as BD to DE, ſince *A* and *B* will move with the Velocity of the Center of Gravity after Impaction.



Corol. IF *B Fig.* 1. is Quieſcent, the Points *B* and *D* will Coincide, and ſince $B.A::AC.BC=DE$ by the Nature of the Center of Gravity, it will be, by Compoſition, $A+B.A::AC+BC=AD.BC=DE$; that is, the Velocity of *A* before Impaction $=AD$ will be to it's Velocity after $=DE$, as $A+B$ the Sum of the Bodies to *A* the Impingent one.

THUS, 1*ſt*, If the Impingent *A* is = to the Quieſcent *B*, $A+B.A::2.1$. 2*d*. If $A.B::1.9$, $A+B.A::10.1$. 3*d*. If $A.B::0.1$, $A+B.A::1.0$, and ſuitably the Velocity of *A* before Impaction will be to it's Velocity after, in theſe ſeveral Caſes, as 2.1, or 10.1, or 1.0, which laſt Caſe is That of a Body Incurring upon a Firm and Immoveable Obſtacle, when, after Impaction, the Impingent *A* becomes Quieſcent.

AGAIN, if the Impingent *A Fig.* 2. is = to *B*, which is not now Quieſcent, but Moves the ſame way with *A*, tho' more ſlowly, ſince the Center of Gravity is in the Middle betwixt them, $AC=BC$, and therefore $CD,=DE$, will be $=\frac{AB}{2}+BD=\frac{AB+2BD}{2}=\frac{AD+BD}{2}$, or the Velocity after Impaction will be Equal to half the Sum of the Velocities before Impaction.

IF farther *A* and *B Fig.* 4. tend to Contrary Sides with Equal Motions, the Points *D* and *C* will Coincide, and $CD=DE$ will be $=0$, that is, after Impaction both the Bodies will be Quieſcent; From whence it is Infer'd, that the Law of the *Carteſians* is falſe, which affirms, that there is always the ſame Quantity of Motion Preſerv'd in the Univerſe, ſince, where Unelaſtick Bodies meet, with Equal Motions, thoſe Motions mutually deſtroy each other.

LASTLY, If Equal Bodies *Fig.* 5. are carry'd to Contrary Sides with Unequal Motions, $DE=CD=CB-BD=\frac{AB}{2}-BD=\frac{AB-2BD}{2}=\frac{AD-BD}{2}$, or the Velocity after Impaction will be Equal to half the Difference of the Velocities before Impaction.

The General Calculation by Algebra. Dr. Keill's Introduct. Theorem 19. Lect. 12.

§. 7. THE General Calculation of what forego's by *Algebra* is as follows; Let the Velocity of the Body *A* be *C*, of *B*, *c*; if the Bodies are mov'd the ſame Way, the Sum of their Motion will be $AC+Bc$, if Contrary Ways $AC-Bc$, but by a Theorem we ſhall ſee afterwards, the Sum of the Motions, to the ſame Side, will continue the ſame before and after Impaction, and therefore will be either $AC+Bc$, or $AC-Bc$, and $\frac{AC+Bc}{A+B}$ or $\frac{AC-Bc}{A+B}$ will Expreſs the Velocity of the Bodies *A* and *B* after Impulſe, and conſequently, if the Body *B* is Quieſcent, that is, if *c* is Equal to Nothing, the Velocity of the Bodies *A* and *B* will be Repreſented by $\frac{AC}{A+B}$.

The ſeveral Objections which lie againſt this Doctrine of the Mutual Concourſe of Hard or Soft Bodies.

§. 8. BUT againſt this Account of the Mutual Concourſe of Hard and Soft Bodies, ſo far as to explain any Thing in Nature by it, it is to be Objected.

FIRST, That the ſeveral Theorems concerning the Center of Gravity are Demonſtrated upon the Suppoſition, that Matter is in it ſelf Homogeneous and alike, nay farther, that it is Endu'd with no Active Properties of it's own, for if it is, tho' it ſhou'd be Granted, that it was Similar, the foregoing Demonſtrations wou'd not ſtand; On the Contrary, we affirm, that it is not Homogeneous or Similar, and that it is Endu'd with Active Properties of it's own, as thoſe in Particular of the Expanſive and Contractive.

SECOND, If therefore Bodies Impinge or Act upon each other, in Nature, whatever they may do, in any one's Fancy, The Sum of their Motions, towards the ſame Side, will not be the ſame before and after Impulſe; nor will the Sum of the Motions before and after Impulſe be the ſame, as if all the Bodies were carry'd with the Velocity of the Common Center of Gravity; nor will the Velocity of the Common Center of Gravity before and after Impulſe continue the ſame; All which Propoſitions this Philoſophy pretends to Demonſtrate.

THIRD, Neither is there any ſuch Hard or Soft Body in the Univerſe, nor can there be Imagin'd or Conceiv'd ſuch an one, which is here ſuppos'd, that in it's Impaction upon another, which is Quieſcent, ſhall proceed exactly along with it, ſo as to divide it's Incurring Velocity betwixt both; Eſpecially, if there is a Peculiar Action belonging to each, and which if you take away, you deſtroy the Matter or the Body it ſelf, which is, what I take upon me to Pronounce and Defend; and that, where we reſt in ſuch Imaginary Abſtractions as theſe, we may as well Propoſe the Logicks of *Burgerſdicius*, or the Eſſay of *Locke*, or the Elements of *Euclid*, which are all mere Abſtractions of the Mind, for Principles to Explain Nature.

FOURTH, On the Contrary, all which is here endeavour'd to be explain'd in the Concourſe of Bodies, and which we find in Fact, may be eaſily Accounted for by the Expanſive and Contractive Forces, which is, that a Body Incurring upon a firm Obex or Obſtacle may be Quieſcent after ſuch Impulſe, that is, if the Body, upon which the Impaction is made, has a Contractive Force Superior to the Expanſive, as in Lead or Clay, which therefore will not Repel the Impinging Body; and proportionably as the Contractive Force more or leſs prevails, the Impinging Body will leſs or more reſult from it, whether the Body, upon which the Impaction is made, is Quieſcent or Moves more ſlowly to the ſame Side; but This we have more fully Diſcours'd of in another Place.

Concerning the Doctrine of Percuſſion. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 13. Theorem 25, 26, 27, 28.

§. 9. IN order to Account for the Concourſe of Elaſtick Bodies, it is firſt Preſum'd, that if a Body, which is mov'd, directly Impinges upon another, which is either Mov'd or Quieſcent, the Greatneſs of the Stroke or Percuſſion will be Proportional to the Moment, which is loſt upon their Mutual Occourſe; for the Greatneſs of the Stroke will be Equal to the Force, which is Impreſs'd from the Percutient on the Body, which receives the Percuſſion, but the Force which is Impreſs'd upon the Body, which receives the Percuſſion, is loſt to the Percutient, by Law the Third of Re-action being Contrary and Equal to Action, and therefore the Motion, which is loſt to the Percutient, will be Proportional to the Force, which is Impreſs'd upon the Body, which receives the Percuſſion, that is, to the Greatneſs of ſuch Stroke or Percuſſion.

FARTHER, If a Body, which is Given, directly Impinges upon another Quieſcent Body, which is Given, the Greatneſs of the Stroke or Percuſſion will be always

Proportional to the Velocity of the Impinging Body; This ſcarcely wants any other Demonſtration upon the Preſent Principles, than Saying, that if the Body is the ſame, which Incurrs upon another, which is Quieſcent, the Greater the Force or Velocity is, with which it Incurrs, the Greater muſt be the Stroke or the Percuſſion receiv'd by the Body, which is Quieſcent; Or, on the Contrary, if the Body, which was before ſuppos'd Quieſcent, Incurrs upon that, which before was ſuppos'd the Incurrent one, and it loſes the ſame Motion, which the Incurrent one loſt before, the Magnitude or Greatneſs of the Stroke or the Percuſſion will be the ſame.

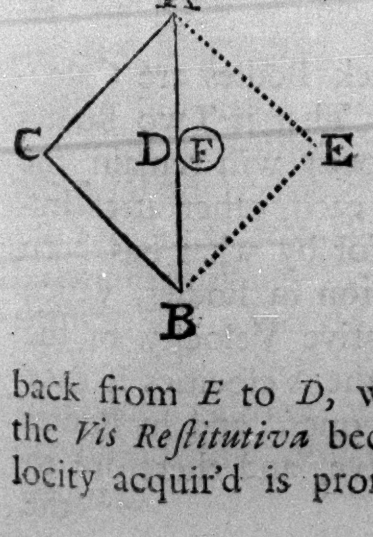
Again, It is told us, that if one Body Impinges directly upon another, which is carry'd more ſlowly to the ſame Side, the Greatneſs of the Stroke or Percuſſion will be the ſame, as if the Preceding Body were Quieſcent, and the Incurring were carry'd upon it with the Difference of their Velocities; Becauſe, by how much more Velocity the Preceding Body is mov'd with to the ſame Side with the Incurring, by ſo much more it declines or avoids it's Stroke or Percuſſion, by which means an Equal Portion of Velocity in the Incurrent will be ſpent without any Effect, and conſequently it will be the ſame, if we ſubſtract an Equal Portion of Velocity from each; from whence the Preceding Body will be Quieſcent, and will now ſtand the Shock of the Incurring, and the Incurring will be carry'd with the Difference of their Velocities; If therefore the Difference of the Velocities continues the ſame, that is, if the Reſpective Velocity do's, with which Two Bodies approach each other, howſoever their Sums are Increas'd or Diminiſh'd, the Greatneſs of the Stroke or Percuſſion will be the ſame.

Lastly, If Two Bodies are carry'd in Contrary or Oppoſite Motions to each other, the Greatneſs of the Stroke or Percuſſion will be the ſame, as if one of them was Quieſcent, and the other Imping'd upon it with the Sum of their Velocities; For the Force of Percuſſion muſt be Evidently the ſame, whether each Body ſtrikes againſt the other with a ſingle Velocity, or one ſtrikes againſt the other, which is Quieſcent, with a Double one, and ſo it will be the ſame, whether they Incurr againſt each other, with Velocities, which are as 2 and 3, 5 and 7, 6 and 9, *&c.* or whether the one Impinges upon the other, which is Quieſcent, with a Velocity of 5, 12, or 15; and therefore, if the Sum of the Velocities continues the ſame, that is, the Reſpective Velocity, with which the Bodies approach each other, whatſoever is the Difference of the Velocities, or however the Velocity is divided betwixt the Two Concurring Bodies, the Greatneſs of the Stroke or Percuſſion will be the ſame; Alſo conſequently in Bodies, which are Given, the Greatneſs of the Stroke or Percuſſion will be Proportional to their Reſpective Velocity.

§. 10. After the Premiſing theſe ſeveral Propoſitions concerning the Force of Percuſſion upon the Mutual Impulſe of Bodies, This Philoſophy proceeds to explain what is meant by Elaſticity.

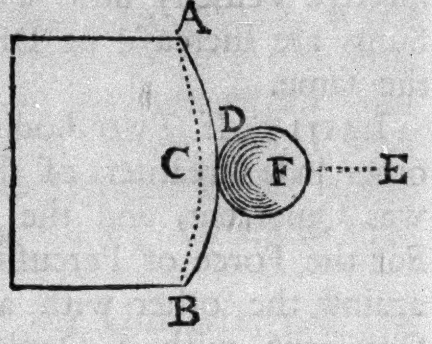
The Doctrine of Elaſticity, and the Cauſe of it explain'd. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 14. Theorem 29. and Probl. 3. Dr. Wallis de Motu, Cap. 13. Part 3. Vol. 1.

And Firſt, it is ſaid, that there are very few Bodies, in which there is not a ſmall Degree of it; for Clay, Wax, and the Like, contain certain Particles of Air in them, by which they become in ſome Meaſure Elaſtick, and from thence it is, that Bodies after Impulſe do not move together, but reſult from each other, and ſometimes are carry'd to the ſame Side, and ſometimes to Contrary ones, with a Different and Various Velocity.



Second, The Cauſe and Manner of Elaſticity or Reſilition is thus Illuſtrated; Let *A B* be a String fixt at the Extremities *A* and *B*, after it is drawn to the utmoſt Stretch, and then let the middle Point *D* be forc'd, from it's Situation there, to *C*, and from thence permitted and reſign'd to it's own Activity; it is Plain the String will not continue in *A C B*, but will endeavour to reſtore it ſelf to it's former Situation in *D*, and having acquir'd a Velocity by the continual Action of the *Vis Reſtitutiva*, it will not reſt in *A D B*, but be carry'd forwards to *E*, till the *Vis Reſtitutiva*, which acts contrary to this acquir'd Velocity, and at length is Equal to it, brings it back from *E* to *D*, which by the acquir'd Velocity is again carry'd towards *C*, till the *Vis Reſtitutiva* becomes Equal to it, and reduces it again to *D*, but by the Velocity acquir'd is promoted towards *E*, till the *Vis Reſtitutiva* again becomes Equal to it, and forces it back to *D*, *&c.* by which means the ſucceſſive Vibrations of the String are produc'd, till it becomes Quieſcent. Let us now imagine the Body *F* to Incurr upon the ſame String; by the Force in the Incurrent Body *F*, the Point *D* in the String will be carry'd to *C*, together with the Body *F*, which Motion will be continu'd, till the *Vis Reſtitutiva*, Acting contrary to the Motion of the Body *F*, is Equal to it, for then all the Motion towards *C* will be deſtroy'd, and the *Vis Reſtitutiva* will reduce the String to it's firſt Situation in *D*, and *F* will be brought back with the ſame Velocity with which the String returns; But upon the Account of the Extreme Tenſion of the String, it will reſtore it ſelf with the ſame Force, with which it was Inflected to *C*, and the Force, with which it was Inflected to *C*, is Equal to the whole Moment of the Impinging Body, which is ſuppos'd to be entirely ſpent upon the Flexion of the String; conſequently, the String will Recommunicate to the Body the Force, which was Imparted to it from it, and the Body *F* will return with the ſame Velocity, with which it Incurr'd, and thus Reflexion is perform'd.

LET us now farther, inſtead of a String, ſuppoſe ſome Elaſtick Body *A B*, and in the firſt Place, that it is Fixt and Immoveable, and let it's Surface *A D B* be compreſs'd Inwards by the Force of the Incurring Body *F*; As ſoon as the Force, which Compreſſes, that is, as ſoon as the Motion of the Body *F* ceaſes, the *Vis Reſtitutiva* will exert it ſelf, and reſtore the Body compreſs'd to it's Priſtine Figure, and urge and repel the Body *F* towards *E*; and if either of the Bodies is perfectly Elaſtick, the *Vis Reſtitutiva* of that Body, which is Elaſtick, will be Equal to the Force, which compreſſes it, that is, to the Moment of the Body *F*, and therefore Re-acting upon the Body *F* with that Force, it will oblige it to Retire with the ſame Velocity, with which it Imping'd: If the Body *A D B C* is not Fixt, but Moveable, the Elaſtick Force will act Equally in both Bodies, and produce Equal Changes of the Motions; For if the Body *A D B* urges the Body *F* towards *E*, it likewiſe will be Equally urg'd to the Contrary Side by the Body *F*, and the Bodies will be mutually Reflected from each other; and thus, it is ſaid, an Account is given, how Bodies after Impulſe are not jointly Quieſcent or Mov'd, but by Reſulting from each other with Different Velocities, ſometimes take Contrary Ways and ſometimes the ſame.



THIRD, The *Carteſians* affirm, that the Reflexion of Bodies is deriv'd from a Continuation of Motion, which cannot be deſtroy'd, the Direction of it being only alter'd, which is endeavour'd to be Refuted by this Philoſophy.

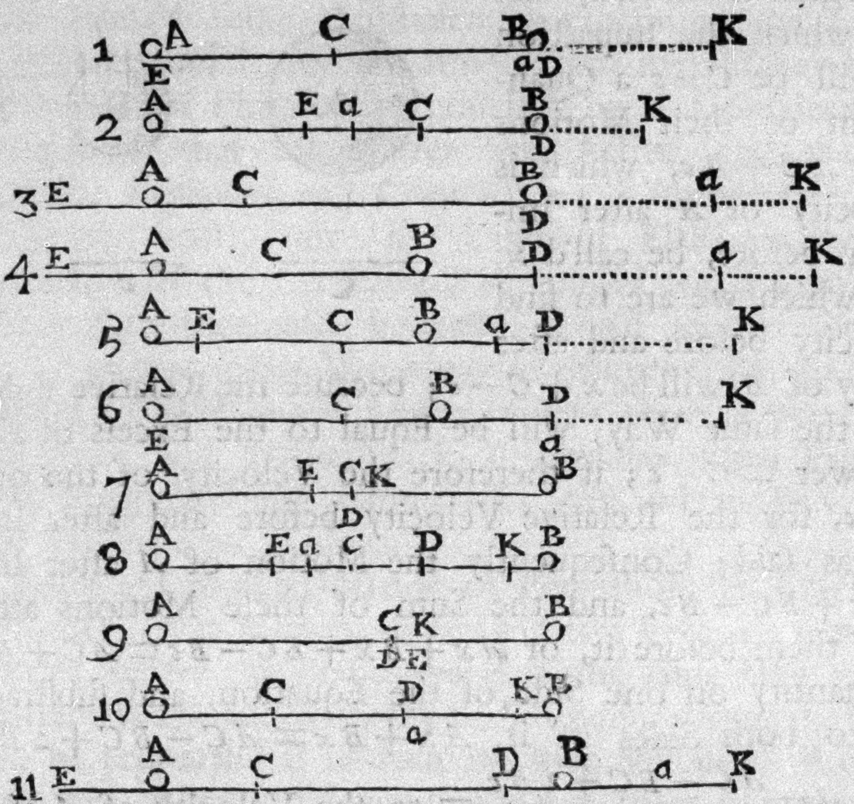
FOURTH, To prove there is ſuch an Elaſticity in Bodies here contended for, by which the Surface of the Elaſtick Body is compreſs'd Inwards by the Incurring Force, and then reſtores it ſelf to it's former Situation, and repels the Incurrent, an Experiment is alledg'd of Two Glaſs or Ivory Globes; of which let one be Quieſcent, and Painted with Ink or any Colour, and the other Impinge upon it, the Impingent, inſtead of being Ting'd in one Point of it's Surface only, which it ought to be, by the Nature of Spherical Bodies, which touch each other in a ſingle Point, will have a Broad Black or Colour'd Spot Impreſs'd upon it, and which is thought cannot poſſibly proceed from any Thing elſe, but the Depreſſion of it's Surface upon Impaction, and which is not afterwards perceiv'd, becauſe it's Elaſticity has reſtor'd it to it's firſt Figure.

The Theorem upon which the Rules of Congreſs in Elaſtick Bodies are calculated and defin'd. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 14. Theorem 29.

§. 11. UPON theſe Principles the Rules of Motion for Elaſtick Bodies are Calculated and Defin'd, and the Twenty-Ninth Theorem is Propos'd; That if Two Bodies perfectly Elaſtick Impinge upon each other, their Relative Velocity will remain the ſame before and after Impaction, that is, they will retire from each other after Impaction with the ſame Celerity, with which they Imping'd; For by what has been ſhewn, the Compreſſive Force, or the Greatneſs of the Percuſſion in Bodies, which are Given, that is, which are the Same, ariſes from the Relative Velocity of the Bodies, and is proportional to it, namely to the Difference of the Velocities if they proceed the ſame Way, and to the Sum of them if Contrary ones, and in Bodies perfectly Elaſtick the *Vis Reſtitutiva* is Equal to the Compreſſive, and therefore to the Relative Velocity or that Force, with which the Bodies were carry'd to each other before Impaction, But by the ſaid *Vis Reſtitutiva* the Bodies are forc'd to depart from each other, and conſequently it's Acting upon them will produce that Relative Velocity in their Return, which they had upon their Acceſs, or, which is all one, will cauſe them to Retire with the ſame Velocity, with which they Imping'd; From whence it is Infer'd by way of Corollary, that if we take Equal Times before and after Impaction, the Diſtances of the Bodies from each other will be Equal, and by conſequence in the ſaid Times, the Diſtances of the Bodies from the Common Center of Gravity will be Equal.

The Rules of Congreſs in Bodies perfectly Elaſtick.

§. 12. FROM the preceding Corollary are the Rules of Congreſs in Bodies, which are perfectly Elaſtick, determin'd. Let A and B be Two Bodies perfectly Elaſtick, whoſe Common Center of Gravity is C, and let the Bodies be ſuppos'd to meet in D, let CE be made Equal to CD, it is affirm'd; That after Impaction EA will repreſent or expreſs the Velocity of the Body A, from E towards A, and EB the Velocity of the Body B, from E towards B; for the Common Center of Gravity, by what has been ſhewn, before and after Impulſe, proceeds uniformly with the ſame Velocity, and therefore, ſince CD is the Velocity of the Center of Gravity before Impulſe, being deſcrib'd by C in the ſame Time as AD is by A, DK, which is made Equal to CD, will be the Velocity of the Center of Gravity after Impulſe; but, by the Corollary juſt now explain'd, in Equal Times before and after Impulſe the Diſtances of the Bodies from the Common Center of Gravity are Equal, and conſequently, if Ka is made Equal to AC, the Body A will be in a after Impulſe, and it's Velocity Da; Farther, as Ka is $=AC$ and $KD=EC$, $Ka-KD=Da$ will be Equal to $AC-EC=EA$, that is, the Velocity of the Body A after Impulſe, will be $=Da$ from D to $a=EA$ from E to A; Alſo the Relative Velocity of the Bodies being the ſame before and after Impulſe, and EA being the Velocity of A, the Velocity of B after Impulſe will be EB from E to B; becauſe whether A and B move the ſame Way, or Contrary ones, the Relative Velocity will be as the Differences, or as the Sums of the Velocities of both the Bodies, or ſuppoſing the Quieſcence of one of them, as the Velocity of the other. *Q.E.D.*



Corol. 1. FROM this Demonſtration it is Infer'd, Corollary the Firſt, that if the Body B is Quieſcent, D and B will be Coincident, as in the Three firſt Figures, and ſince $B.A::AC.CB$ by the Center of Gravity, by Compounding, $B+A.A::AC+CB=AB.CB$, and by doubling the Conſequents, $B+A.2A::AB.2CB=EB$, or the Sum of the Bodies will be to Twice the Impinging Body, as the Celerity of the Impinging Body before Impaction, to the Celerity of the Quieſcent Body after it.

Corol. 2. THEREFORE if $A=B$, *Fig.* 1. $A+B=2A$, and EB the Celerity of B after Impaction $=AB$ the Celerity of A before it, and therefore A and E Coinciding, AE the Celerity of A after Impaction $=0$.

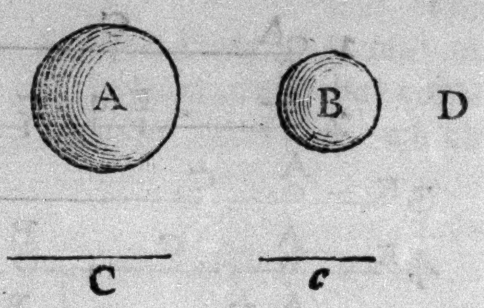
Corol. 3. IF $A=B$, *Fig.* 4. and they are carry'd to the ſame Side, they will after Impaction be carry'd to the ſame Side, and exchange Celerities with each other; For ſince $CE=CD$ by Conſtruction, and $AC=CB$ by the Center of Gravity, $CE-AC=EA=CD-CB=BD$, and therefore EA the Celerity of A after Impaction $=BD$ the Celerity of B before it; Farther, ſince $EA=BD$, $EB=AD$, becauſe the Relative Celerity, both before and after Impaction, continues the ſame, and therefore EB the Celerity of B after Impaction will be Equal to AD the Celerity of A before it.

Corol. 4. If $A = B$, *Fig.* 8. and they are carry'd to Contrary Sides, after Impaction they will recede to Contrary Sides and exchange their Celerities; For ſince $AC = CB$ by the Center of Gravity, and $EC = CD$ by Conſtruction, $AC - EC = AE = CB - CD = BD$, and therefore EA the Celerity of A after Impaction $= BD$ the Celerity of B before it; Farther, ſince $EA = BD$, $AD = EB$, becauſe, the Relative Celerity before and after Impaction continues the ſame, that is, EB the Celerity of B after Impaction will be Equal to AD the Celerity of A before it.

The foregoing Rules Algebraically Demonſtrated.

§. 13. This Doctrine Algebraically is thus Demonſtrated.

1. Let us firſt ſuppoſe the Bodies A and B, whoſe Bulks are known, to be carry'd to the ſame Side, and let C, a Quantity known, be the Velocity of the Impinging Body A, and c, alſo a Quantity which is known, that of the preceding Body B, upon which the Impaction is made, the Relative Velocity will be $C - c$ a Quantity likewiſe known, and the Sum of their Motions towards the ſame Side will be $AC + Bc$, which is therefore known; let the Velocity of A after Impaction, towards the ſame Side as before, be call'd x, being a Quantity unknown, and which we are to find out, and ſince the Relative Velocity before and after Impaction is the ſame, the Velocity of B will be $x + C - c$; becauſe the Relative Velocity of Bodies, which are mov'd the ſame Way, will be Equal to the Exceſs of the Swifter Velocity above the Slower $= C - c$; if therefore the Velocity of the one is x, the other muſt be $x + C - c$, for the Relative Velocity before and after Impaction continues the ſame, as was ſaid; Conſequently the Motion of A after Impaction is $= Ax$, and of $B = Bx + BC - Bc$, and the Sum of theſe Motions after Impaction is Equal to the Sum of them before it, or $Ax + Bx + BC - Bc = AC + Bc$, and by leaving the unknown Quantity on one Side of the Equation, and ſubſtracting BC from and adding Bc to both Sides of it, $Ax + Bx = AC - BC + 2Bc$, and by dividing each by $A + B$, $x = \frac{AC - BC + 2Bc}{A + B}$ = to the Velocity of A after Impaction; but the Velocity of B is $= x + C - c$ after Impaction $= \frac{AC - BC + 2Bc}{A + B} + C - c = \frac{AC - BC + 2Bc + AC + BC - Ac - Bc}{A + B} = \frac{2AC - Ac + Bc}{A + B}$. If therefore BC is Greater than $AC + 2Bc$, x or $\frac{AC - BC + 2Bc}{A + B}$ will be a Negative Quantity, and conſequently, the Velocity of the Body A will be towards the Contrary Side, and it's Motion towards D will be Negative, that is, from it. If B is Quieſcent, or $c = 0$, the Velocity of A after Impaction is $= \frac{AC - BC}{A + B}$, either forwards or backwards, as $+$ or $-$ prevails.



2. Let us now ſuppoſe A and B to be carry'd with the Velocities C and c to contrary Sides, the Sum of their Motions to the ſame Side will be $AC - Bc$, and their Relative Velocity, where they meet each other, $C + c$; let the Velocity of A after Impaction be x, and it's Motion, towards the ſame Side as before, will be Ax, the Velocity alſo of B after Impaction will be $x + C + c$, becauſe the Relative Velocity $C + c$ continues the ſame after Impaction, and the Motion of B towards D will be $Bx + BC + Bc$, and the Sum of the Motions towards the ſame Side $Ax + Bx + BC + Bc$ after Impaction $= AC - Bc$ the Sum of 'em before it, and therefore $Ax + Bx = AC - BC - 2Bc$, and $x = \frac{AC - BC - 2Bc}{A + B}$ the Velocity of the Body A after Impaction, and $x + C + c = \frac{AC - BC - 2Bc}{A + B} + C + c = \frac{AC - BC - 2Bc + AC + Ac + BC + Bc}{A + B}$

$= 2AC$

$= \frac{2AC + Ac - Bc}{A + B}$ the Velocity of B after Impaction. If therefore $BC + 2Bc$ is Greater than AC, x will be a Negative Quantity, or A after Impaction will be carry'd backwards and retire from D; The Expreſſions above of the Velocities of A and B after Impaction are exactly Analogous to what we find in Sir *Iſaac Newton*'s Algebra, Problem. 12. Pag. 91. and in my worthy Friend the Reverend Mr. *Morgan*'s Comments upon *Rohault*; and in theſe Laws of perfectly Elaſtick Bodies, both *Chriſtian Hugens* and Sir *Chriſtopher Wren* did alſo agree, tho' calculated ſeparately and diſtinctly by them; and no wonder, ſince they all depend upon the ſame Principle of a perfect Elaſticity, a Notion originally deriv'd from Dr. *Wallis*, and which many Years ago I particularly examin'd, and wrote ſeveral Papers in Confutation of it, which are ſome where by me, but not occurring, I ſhall here repeat that Trouble.

Rohault's Phyſ. Cap. 11. Par. 1. Edit. 3.

An Examination of the foregoing Doctrine of Percuſſion.

§. 14. I once was in Hopes, that from theſe Laws of Elaſtick Bodies I ſhou'd have receiv'd ſome Aſſiſtance in explaining the Laws of Nature; for having been long ſince, and I may ſay almoſt from my Infancy in this Univerſity and from my firſt Study of Philoſophy, poſſeſs'd, by a Conſideration of Material Beings, with a Perſuaſion, that all Matter was Active, and that it's Forces might be reſolv'd into the Expanſive and Contractive; I immediately concluded, that when I came to ſearch ſtrictly into the Laws of Elaſticity, which ſeem'd to have ſome Reſemblance of the Expanſive I contended for, I ſhou'd there find ſomething pertinent to my Enquiries, and at leaſt I ſhou'd receive ſome Light and Information from thence of the ſecret Workings of Nature; But to my great Diſappointment, when I came to look more narrowly into them, I perceiv'd they were nothing elſe but Abſtracted and Mathematick Reaſonings upon Principles and Suppoſitions, which were Imaginary and Chimerical, and which had no Foundation in the Reallity and Exiſtence of Things.

THUS, As to the Doctrine of Percuſſion, in which it is affirm'd, that the Force or Greatneſs of it is Equal to the Relative Velocity, that is, to the Difference of the Velocities, where the Bodies proceed the ſame Way, and to the Sum of them, where contrary Ways, and that, the Bodies being given, the Force or Greatneſs of Percuſſion will be proportional to ſuch Relative Velocity, We ſay, that the Demonſtrations of This depend upon a Suppoſition, that there is nothing to be conſider'd in Matter but the Force of it's Velocity, that it is Similar and has no peculiar Forces of it's own, for if it had, theſe Computations of the Force of Percuſſion, from the Difference or Sum of the Velocities of the Incurring Bodies, wou'd be quite diſorder'd and confounded, and it wou'd be Impoſſible for us ever to know, what the Force of Percuſſion wou'd be, without underſtanding the Nature of thoſe Forces, which reſide in the Bodies themſelves; For Inſtance, let Fire and Water meet, I ſuppoſe the Force of Percuſſion will not be readily determin'd by the Rule of Relative Velocity, and ſomething more muſt be firſt Explain'd, that is, the Nature of the Force of theſe Two Bodies, before we can pronounce, what will be the Reſult and Effect of their Congreſs.

The Doctrine of Elaſticity examin'd.

§. 15. As to Elaſticity, in the Beginning of the Tenth Section it is confeſs'd, that there are few, if any Bodies, which are not endu'd with ſome Degree of it, as even Clay and Wax have ſome; from whence it is plain, that the Doctrine, Deliver'd before, concerning Bodies, which are perfectly Hard or Soft, is acknowledg'd to be a Creature of the Mind, without any ſuch Bodies Exiſting in Nature; and therefore it is ſaid, that after Impulſe they do not move together, but reſult from each other with varying Velocities; whereas this Elaſticity yet is aſcrib'd to Particles of Air Inſinuating themſelves into, and reſting in the Pores of theſe Bodies, it ſeems to be a mere Fiction, and we may as well attribute the Tranſparency of Glaſs to Tranſparent Particles of Air diſpers'd in it's Pores, as the Elaſticity of Bodies to Elaſtick Particles of Air lodg'd in Them; For why may not Bodies be in themſelves, in ſome Degree or other, Elaſtick, as well as Air is, unleſs becauſe the Preſent Philoſophy of Paſſive Matter cannot account for it's Elaſticity without Introducing ſuch extraneous Particles? Which is no Objection to us, who aſſert an Active Matter, and that all Matter has a Proportion and Degree of the Expanſive; Beſides, this Fancy of the Elaſticity of Bodies, being deriv'd from Elaſtick Particles of Air mixt with them, is

Contrary to the following Explanation of it, which reſigns it to the *Vis Reſtitutiva* in Bodies themſelves.

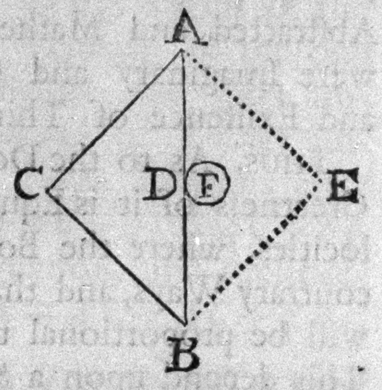
The Vis Reſtitutiva *gives no Solution of what Elaſticity is.*

§. 16. That there is ſuch a Phænomenon or Effect in Nature, as Elaſticity, or a Force of Reſilition, by which Bodies are Driven and do Recoil from each other, is beyond Diſpute, being confirm'd by daily Experience, but that the *Vis Reſtitutiva* is not an adequate Cauſe of ſuch an Effect, I ſhall now Evince.

For there is no Satisfaction given us, how this *Vis Reſtitutiva* comes to be inherent in ſome Bodies, and not in Others, or at leaſt not in the ſame Degree, whence it is deriv'd to, and how it ſubſiſts in them; there is nothing Explicitly ſaid of it, which ſhou'd make us not conclude it a Fictitious Force, and to have it's Being in the Imagination only; which is not the Caſe of the Expanſive and Contractive we Defend, which we have already ſhewn to Exiſt in all Nature in Various and Different Proportions, and have explain'd the mediate Sources, from whence they are deriv'd, tho' ultimately from God himſelf.

Besides, that the *Vis Reſtitutiva* is an Imaginary Force invented by Philoſophers, on purpoſe to account for this particular Difficulty in Nature, is Evident from hence, that it is not made uſe of upon any other Occaſion, nor is it connected with the Explanation of any other Phænomenon whatſoever; whereas the ſame Expanſive and Contractive Forces, which we alledge for the Solution of this, are connected with and extended to all other Appearances, we can name, of Solidity and Fluidity, Hardneſs and Softneſs, Gravity and Levity, Cold and Heat, Opacity and Tranſparency, &c.

Farther, the Explication, which is given of the *Vis Reſtitutiva*, ſhews it to be an Imaginary Force, a mere Invention of the Philoſopher, without any Ground or Foundation in Nature or Reaſon; ſince, altho' this *Vis Reſtitutiva* ſhou'd be allow'd to the String *ADB*, when drawn by an External Force to *ACB*, by which it might reduce it to it's former Situation in *ADB*, how the ſame *Vis Reſtitutiva* ſhou'd propel and carry it from thence to *AEB* is inconceivable, unleſs the Force, which reſtores it to it's firſt Situation, has the Power to repel it from that Situation, that is, unleſs the *Vis Reſtitutiva* to a certain Situation, is a *Vis Repulſiva* from it, which is a Contradiction; and for the ſame Reaſon, granting it Poſſible for the *Vis Reſtitutiva* to propel the String from *ADB* to *AEB*, how the ſame *Vis Reſtitutiva* ſhou'd bring it back from *AEB* to *ADB* cannot be Imagin'd, and ſo it may be argu'd in it's Second Progreſs to *ACB*, and Regreſs to *ADB*, or it's Second Progreſs to *AEB*, and Regreſs to *ADB*, or in it's Third, Fourth, Fifth, &c.



This Philoſophy ſeems to have been aware of the foregoing Difficulty, and therefore aſcribes the Progreſſes to the Velocity acquir'd from the Motion of the String, and the Regreſſes to the *Vis Reſtitutiva*; But can there be any Velocity acquir'd, which is not owing to ſome Cauſe? And is there any Cauſe aſſign'd excepting that of the *Vis Reſtitutiva?* And can a Velocity acquir'd from the *Vis Reſtitutiva* act againſt and in Oppoſition to the *Vis Reſtitutiva* from whence it is deriv'd? It is altogether abſurd to ſuppoſe it; and we may as well affirm, that if we Impel a Body one Way, it will move a Contrary one from that Impulſe without any other Direction.

Elaſticity ſolv'd from the Doctrine of the Expanſive and Contractive Forces.

§. 17. On the other Hand, the Expanſive and Contractive Forces give a plain Account of this Phænomenon, for *A* and *B* being Two fixt Points, upon which the Tenſion of the String is made, they are Two Centers of Contraction, towards which the Intermediate Parts of the String are urg'd, and betwixt which they are Attracted and Drawn; Again, the Parts about *D*, which are the fartheſt from the Centers of Contraction, will be the leaſt Affected by their Influences, and conſequently will have leſs of the Contractive and more of the Expanſive Force, to which if we add the Expanſive Force of the Finger drawing the String from it's Contractive Situation, or the Expanſive Force of the Velocity of the Incurring Body *F*, here will be Two Contrary Forces, the Contractive and Expanſive, Acting againſt each other, by which means a Conteſt will be rais'd and continu'd betwixt them, till the one or the other prevails, and mutual Reciprocations excited, till the String becomes Quieſcent.

Thus, when the String is in *C*, the Expanſive Force, tho' Inferior to the Contractive, ſtruggles and acts againſt it, and if it ſhou'd be Increas'd ſo far as to break it, the Expanſive wou'd then prevail and be Superior, and the Contractive Force from *A* and *B* wou'd obtain no farther Effect; but the Expanſive at *C* being Inferior to the Contractive in *A* and *B*, it is forc'd to yield to the Contractive, which reduces the String to *ADB*, notwithſtanding which, a Portion of the Expanſive ſtill ſubſiſting in the String, and being not Entirely vanquiſh'd and ſubdu'd by the Contractive, it now exerts it ſelf towards *E*, ſtill in Oppoſition to the Contractive in *A* and *B*, to which it is always Contrary, till it is again made to yeild to the Contractive, and the String is brought back to *D*; and thus the Progreſſes and Regreſſes are perform'd, the firſt by the Power of the Expanſive Force, and the laſt by that of the Contractive, till the impreſs'd Inferior Expanſive is ſpent and ſuccumbs, and the Contractive prevails, and therewith the String obeys the Superior Force, and at length becomes Quieſcent betwixt the Two Centers of Contraction *A* and *B*.

So likewiſe, for the Caſe is much the ſame, ſuppoſing Two Bodies, which are in an Equal Balance with each other, to be ſuſpended upon their Common Center of Gravity, which being the Point, by which they are detain'd in their Æquilibrium, is a Center of Contraction, and that Force, which is Impreſs'd upon them from the Earth's Contraction, is a Force of Expanſion, by which they tend from their Center of Gravity towards the Earth; if therefore by Impulſe a new Expanſive Force is Communicated to the Balance, the Bodies will riſe and fall by Turns from this Expanſive, till the Force is ſpent and the Contractive prevails, whereby the Bodies become Quieſcent; that is, *D*, by an Expanſive Force, Oſcillating upon *A* and *B* the Contractive ones, will not be much Different (as to the Manner of theſe Forces acting) from *A* and *B*, by an Expanſive Force, Oſcillating upon *D* a Contractive; In both Inſtances, the Expanſive Force will carry the String or the Balance out of the Line *ADB*, and the Contractive will reduce them to it, till the Expanſive is overpower'd and over-comn, and in the End ſubmits to the Contractive.

§. 18. The Expanſive and Contractive Forces are not only capable of ſolving the preſent Phænomenon, which the *Vis Reſtitutiva* cannot do, but alſo, as will be ſhewn afterwards, all the Properties of Matter whether Eſſential or Accidental, and upon which Account we affirm Action or Force, which is divided into an Expanſive and Contractive one, to be the very Eſſence of Matter; What I mean, is, that Matter is Action or Force it ſelf, and not the Support, Subſtratum, or Seat of it; but this we ſhall perhaps have another Opportunity of ſpeaking more largely to.

A Summary Account of the Doctrine of the Expanſive and Contractive Forces, and of their Extenſiveneſs in ſolving the Effects of Nature.

What we ſhall take Notice of at Preſent, by way of Anticipation, is, that this Doctrine makes only Two Principles in Nature, the Expanſive and Contractive, both Contrary to each other, and both reſolvible into one Principle of Action; which, in Reſpect of the Being of a God, is agreeable to our Notions of one Supreme and Superintending Agent, and indeed is an Evident Proof of one, and alſo explains the Reaſon, why ſome have imagin'd Two Gods, the one the Author of Good, and the other of Evil, in Compliance with theſe Two diſtinct and oppoſite Forces; And in Reſpect of Nature, what is more Evident than that the Whole of it, as to the Material or Immaterial Part, is diſtinguiſh'd into Effects, which are either Contrary to each other, or mixt and compounded of ſuch as are?

Thus, as to the Material Part, there are Light, Heat, Tranſparency, Fluidity, Levity, Elaſticity; and in Relation to Colours, Red, Orange, Yellow; to Taſts, Sweet and Luſcious; to Smells, Fragrant; to Sounds, Harmonious and Soft, which fall under the Expanſive, in which yet there is ſome Mixture of the Contractive; whilſt the Contrary Qualities, as Darkneſs, from the Earth's Contraction of the Medium which the Sun Expands, Cold, Opacity, Solidity, Gravity, Unelaſtickneſs; and in Relation to Colours, Blue, Violet, and Black, (for Green Lies Intermediate to both the Orders); to Taſts, Acid and Sower; to Smells, Fœtid; to Sounds, Harſh and Dull, ſeem to derive their Origin chiefly from the Contractive, tho' not without ſome Degree of the Expanſive in their Compoſition.

Also, as to the Immaterial World, and that Thinking Subſtance, which Animates and Informs us, tho' it is Different and Diſtinct from Matter, yet has it's Expanſive and Contractive Forces; Thus Gaiety, Wit, Memory, and Recollection, Levity, Courage, Raſhneſs, and Fool-Hardineſs, Fierceneſs, Hatred, Haughtineſs, and Inſolence, Anger, Revenge, Ill-Nature, and Covetouſneſs, Appear to be deriv'd from the Expanſive Force of our Minds, by which we Repel others from us; On the Contrary, Gravity and Judgment and Reaſoning, a Generoſity and Fear of Offending others and a Love of them, Dejection of Spirit, Clemency and Compaſſion, and the Like, are from the Contractive Force of them, by which we Draw and Attract others to us; and all the Various Paſſions and Affections of our Minds have a Greater or Leſs Degree and Proportion of the Expanſive or Contractive Force in them, or are compounded of them; And by this Means, by the Mind and Matter agreeing in theſe Forces, we ſuppoſe their Union is effected, tho' Thought and the Mind it ſelf is manifeſtly Different from theſe Forces, and in the ſame Manner, as Almighty God is diſtinct from the Univerſe, which yet he has been pleas'd to Fill and Actuate with them.

A Continuance of Motion is produc'd, ſo long as there is a Conteſt maintain'd betwixt the Two Oppoſite Forces, the Expanſive and Contractive.

§. 19. BUT to leave theſe Diſquiſitions at Preſent, which we may perhaps ſome other Time reſume, ſince we only intended to ſhew in General here the Extenſiveneſs of theſe Principles of the Expanſive and Contractive Forces, we ſhall farther obſerve from this Explanation of Elaſticity by them, that a Continuance of Motion is produc'd, ſo long as there is a Conteſt maintain'd betwixt the Two oppoſite Forces, the Expanſive and Contractive, but when the one or the other entirely Prevails, the Effect of the other Ceaſes; thus if, in the Tenſion of a String, the Expanſive Force is leſs than the Contractive, there is a Reciprocation of the Progreſſes and Regreſſes of it, till the Expanſive is Subdu'd and the Contractive is Predominant, by Reducing it at length to a Quieſcence in *ADB*; if therefore now the Expanſive Force, Acting towards *C*, was Conſtant and Regular, and Equal to the Contractive from *A* and *B*, there wou'd be an endleſs Reciprocation of Motion, and the Progreſſes and Regreſſes wou'd be continu'd for ever, from whence a Perpetual Motion wou'd ariſe; but if the Expanſive ſhou'd be Superior to the Contractive, the String wou'd Break and be Diſſolv'd, and the Effects of the Contractive Forces from *A* and *B* wou'd be Deſtroy'd.

Where Two Forces are Equal and Contrary, there will be a Perpetual Motion and Conteſt betwixt them, and if the one or the other prevails, the Effect of the Oppoſite Force will be ſo far ſuperſeded, and this is a General Law of Nature.

§. 20. FROM hence therefore we may lay down this for a Law of Nature, that where Two Forces are Equal, and are Contrary in their Genius and Temper, and Act againſt each other, as the Expanſive and Contractive, there will be a Perpetual Motion and Conteſt betwixt them, neither Prevailing againſt the other; but if the one or the other Prevails, the Effect of the oppoſite Force will be Superſeded, and Vacated in ſome Degree, tho' not entirely Deſtroy'd and Annull'd.

THUS alſo, if *ADB* is conſider'd as a Balance, in which the Bodies *A* and *B* are Equally Pois'd upon *D*, if the Expanſive Force, from Impulſe upon *A* or *B*, is Leſs than the Contractive in *D*, there will be a Reciprocation of Motion till the Balance reſts in *ADB*, and ſubmits to the Contractive in *D*; On the Contrary, if the Expanſive Force, from Impulſe upon *A* or *B*, is Greater than the Contractive in *D*, it will ſtrike off the Body *A* or *B*, and free it from it's Center of Contraction in *D*; But if the Expanſive Force in *A* or *B* is Equal to the Contractive in *D*, ſuch a Body muſt be Perpetually mov'd backwards and forwards about it's Center *D*, by Continual Oſcillations, without being ever Quieſcent in the Line *ADB*; and if *A* or *B* is now taken off, which is an Equal Poiſe to the other, the Remaining Body muſt be carry'd in a Continual Revolution round the Center of Contraction; For ſince neither the Contractive nor Expanſive Force are ſuppos'd to Prevail, but are Equal, there muſt a Perpetual Motion enſue, and ſince it cannot be to the Contractive Force nor from it, for then the one or the other wou'd Prevail, nor yet backwards and forwards by Way of Oſcillation, becauſe one of the Bodies is now taken off from the Æquilibrium which caus'd ſuch Oſcillation, it muſt be in an Orbit round it.

THAT this Law of Nature obtains in all Material Beings, is Evident; Thus in the Contractive Force of Fuel and the Expanſive of Fire, there is a Motion produc'd and continu'd ſo long, as there is a Contention betwixt thoſe Two Forces; If the Expanſive of the Fire is Superior, the Contractive is ſubdu'd, and the Fuel reduc'd to a Light and Expanſive Aſhes, with little or no Contraction belonging to them; If the Contractive Prevails, the Expanſive Ceaſes, and the Fire is Extinguiſh'd; And if an Equal Balance is kept up betwixt the Expanſive of the Fire, and Contractive of the Fuel, by a continual Addition of the Latter, in a juſt Proportion to the Former, the Motion and the Fire becomes Perpetual, the Air, which is always neceſſary to the Being of Fire, having the Nature of the Expanſive, and Concurring with it.

§. 21. **From** what foregoes, the Reaſon, why a Perpetual Motion cannot be found out in our Earth is, becauſe the Contractive Force of the Earth and the Bodies which belong to it, is Infinitely Superior to the Expanſive, deriv'd from the Sun, or from any Subterraneous Fires; which, in all Probability, were originally owing to ſome Accenſion of Inflammable Matter, and that Accenſion to the Sun, or to the Artificial Methods we have of Producing Fire, by the Means and Aſſiſtance of it; and therefore all the Interior Parts of the Earth, we may Reaſonably think, are of a Strong and Contractive Force, and that, the Nearer we come to the Center of it, the Matter is the more Compact and Denſer.

Why a Perpetual Motion cannot be found out, and why yet there is one in the Heavens.

On the Contrary, the Reaſon, why we have a Perpetual Motion in the Heavens, is, becauſe the Expanſive Force of the Sun and the Contractive of the Planets are in their ſeveral Diſtances nearly Equal, and from which Continual Struggle and Conteſt betwixt the Sun and them, the Conſtant Periods, which they keep, do Ariſe. And, as theſe Forces of the Sun and Planets vary, They come Nearer to, or retire Farther from it.

§. 22. **This** Law of Nature is likewiſe manifeſt from the Mixture of what the Chymiſts call *Acid* and *Alkali*, which we have more particularly Diſcours'd of in another Place, and ſhall here only conſider them, ſo far as they juſtify the Preſent Law; for, whilſt neither the Expanſive nor the Contractive Force prevail, there is an Effervеſcence and an Ebullition produc'd, but ſo ſoon as the Contractive has the Aſcendant, a Coagulum or a Precipitation is cauſ'd, and when the Expanſive of Spirit of Nitre, a Bright and Tranſparent Fluid ſucceeds; Thus alſo Winds, Tempeſts, and Hurricans in the Air, Follow from a Contention betwixt the Expanſive of the Sun, and the Contractive of the Earth and Cold, which therefore with us Generally happen betwixt Summer and Winter, that is, in Spring or Autumn, when the Expanſive and Contractive Forces are the neareſt to an Æquilibrium, and before the Expanſive is Predominant in Summer, and the Contractive in Winter.

The foregoing Law farther Evinc'd.

Why Winds and Tempeſts are rather in Spring or Autumn, than in Summer or Winter.

Farther, in Natural Bodies, which are all of them produc'd by a Preceding Fermentation, as Liquids from Fruits, which are evidently Raiſ'd from the Expanſive Force of the Sun, and from the Contractive of the Earth and Soil in which they Grow, there is firſt a Motion and Vegetation ariſes from theſe Two Contending Powers, this Conteſt is afterwards continu'd by Fermentation, which is owing to the Mixture of the Expanſive and Contractive Force, till at length the Expanſive prevails and ſettles in a Fluid, in which the Contractive has it's Effect, which is Evident from it's Continuity and Gravitation, but is Inferior to the Expanſive by it's Fluidity, Lightneſs, and Tranſparency.

How Liquid Bodies are Form'd.

On the other Hand in the Formation of Solid Bodies, as Wood and Metals, there is a Fermentation from the Expanſive and Contractive Force, till at length the Contractive prevails, and makes the Body, like the Coagulum before mention'd in Chymiſtry, Opake, Solid, and Heavy, but yet not ſo, as entirely to Deſtroy or Annull the Expanſive, which Shows and Exerts it ſelf in Elaſticity, Colour, and in a Greater or Leſs Degree of Levity, as the Expanſive is leſs or more ſubdu'd by the Contractive.

How Solid Bodies are Made.

§. 23. **And** from hence we may have a juſt Account of what Earth, Fire, and Water is, the Former being that Matter, in which the Contractive moſt prevails, and the Latter in which the Expanſive; that is, where the Expanſive Force of the Sun has juſt ſo much Power, as to Raiſe the Contractive Force of our Planet into a Fluidity, it becomes Water, where into an Inflammability, it becomes Fire, where into Fermentation, it becomes a Vegetable or a Metal, and where into none of theſe, it becomes Earth; ſo that all theſe Phænomenons in Nature ſeem only to be Deriv'd from the Various Proportions, Mixtures, and Degrees of the Expanſive and Contractive Forces, which Exiſting in Separate and Diſtinct Portions conſtitute all the Bodies we behold, and in one General and Unlimited Diffuſion, that Plenum we contend for, by which all the Material Beings in the Univerſe are Connected into one continu'd Active Subſtance, Originally Deriv'd and Produc'd from one Infinite and Almighty Agent, the Supreme Orderer and Governor of all Things, God; From whence it will Appear, that tho' Space is Full, yet that it is not Equally ſo, there being Different Forces and Actions, ſome

What Earth, Water, Air, Fire, Matter, and Plenum is, and how reduc'd to Geometry.

Sir Iſ. Newt. Princip. Prop. 6. Corol. 3. Lib. 3. Edit. 2. Compar'd with Edit. 1.

Thicker and Denſer, and Others more Feeble, Diluted, and Languid, as thoſe of Gold on the one Hand, and Water or Air, or Æther on the other, in the ſame or Equal Portions of the ſaid Space: This was firſt Affirm'd by us in the Philoſophy, which we ſome Years ago Publiſh'd in Oppoſition to a Vacuum, which has been ſince Subſcrib'd to by the Modern Philoſophy, but without Explaining how Space is not *Equally full*, which we have here done. From hence alſo is Deriv'd a True and Proper *Geometry* of *Matter* hitherto unknown to Philoſophers, becauſe where they make Matter an Abſtracted and Homogeneous Subſtance, it is Impoſſible it's Nature ſhou'd admit of Quantities and Proportions; On the Contrary, we who affirm Matter to conſiſt of Various Degrees of Forces in the ſame Space, it is no Wonder, that we may be allow'd to Diſcourſe of the Mathematicks and Quantities of it.

Geometria
Solidorum
ſive Materiæ.

The ſame Law of Nature Confirm'd from the Immaterial or Thinking Part of it.

§. 24. But to proceed upon the Preſent Law of Nature, which is alſo Confirm'd from the Immaterial and Thinking Part of it; We plainly Experience, that all Quarrels and Diſſenſions, which are properly the Motions and Agitations of Men's Minds, Ariſe from Oppoſite and Different Qualities in them, that is, from the Expanſive and Contractive Forces which belong to 'em; Thus Wit, Gaiety, and Mirth, are conſtantly at Variance with Judgment, Sedateneſs, and Gravity; Vice Combats with Vertue; Inſolence and Pride with Modeſty and Humility; Cruelty with Clemency and Compaſſion; Extravagance and Licentiouſneſs with Sobriety and Goodneſs; and Covetouſneſs and Ill-Nature with Generoſity; and as theſe Principles of our Minds are Diametrically Contrary to each other, and as the Firſt ſeem to be of the Expanſive Sort, or the Repulſive, by which others are Alienated from us, and the Laſt of the Contractive, by which They are Allur'd or Drawn towards us, ſo where-ever we find Men of theſe Tempers, which are Reluctant to each other, we as certainly find they Diſagree, and that the Contention laſts till the one Force or the other, the Expanſive or Contractive, Prevails, and then all is Quiet and Compos'd, tho' the Force which ſubmits to the other is not entirely Deſtroy'd or Annull'd.

Why the Good and Vertuous Qualities of Men's Minds Generally in the Iſſue prevail againſt the Ill, in Bodies and Societies of Men.

§. 25. And ſince, as we have before ſhewn, the Expanſive Force on the Earth is but Small and Inconſiderable in Reſpect of the Contractive, therefore, tho' the Expanſive may ſometimes prevail, yet Generally ſpeaking, and at length the Contractive will; and conſequently from hence it is Evident, that tho' Wit, Gaiety, and Mirth may have it's Proſelytes, and Vice, Pride, Cruelty, Extravagance and Licentiouſneſs, Covetouſneſs and Ill-Nature may prevail for a Time, yet Judgment, Gravity, Sedateneſs and Seriouſneſs, Modeſty, Humility, Clemency and Compaſſion, Sobriety, Goodneſs and Generoſity will have the Strongeſt Force, and be in the End too hard for the other; and thus it was, in part, that the Chriſtian Morals became Superior to all the Ill-Qualities and Affections of Men, which Exerted themſelves in Oppoſition to them, and thus the Vertues of Human Society have been ſtill maintain'd and preſerv'd to it, notwithſtanding the Continual Struggles of the Vices of Men to Extirpate and to Eradicate them.

Why the ſame Obtains in ſingle Perſons, and why they ſeem Contrary to Themſelves.

§. 26. If now we come to the Minds of ſingle Perſons, without Comparing them with thoſe of others, there are always Two Forces obſervable in them, the Expanſive and Contractive, by which the ſame Perſon ſeems Contrary to himſelf in a Thouſand Qualities, and is really Different as the one or the other Prevails; and whilſt there is a kind of Equal Balance betwixt them, there is a continual Conteſt, Agitation or Struggle in a Man's own Breaſt, till the one or the other, is ſubdu'd; Thus every Man has the Seeds in his own Nature of Vertue and Vice, and of all the oppoſite Qualities and Affections we can Imagine, but they are in ſuch an Æquilibrium, and ſo ordain'd by the Almighty and All-wiſe Agent, that it is in every ones Will and Power to determine the Balance on the one Side or the other, that is, to the Expanſive or Contractive; Whilſt this Conteſt laſts, the Mind is in a Ferment and Uneaſy, that is, in it's Paſſage from the Vitious Qualities of the Mind to the Vertuous, or on the Contrary from the Vertuous to the Vitious, but when Either of them Prevails, the Mind is in a State of Compoſure and Quieſcence, and Satisfaction in the firſt Caſe, and in the Laſt in a State, which may be Agreeable for a Time; but when the Contractive renews the Conteſt, as it will do, when the Expanſive is Weaken'd, as in Sickneſs or near Death, there is a Reluctance and Uneaſineſs, a Motion, a Ferment and Agitation in the Mind, which cauſes the Greateſt Pains, which can Appertain to it; And from hence, that is, from the Different Degrees and Proportions

From hence a Pſycheometria

portions of the Expanſive and Contractive Forces in Men's Minds are their Natures and Identities aſcertain'd, and therefore the Powers and Faculties of it are as much Reducible to Mathematicks and Proportions, or a *Pſycheometria*, as any other Quantities whatſoever, The Elements of which I promiſ'd in the *Principles of Philoſophy*.

From hence the Foundation of Morality, and the Reaſon of Religion.

This will alſo give us an Account of what Morality is, and what the Foundation of it, ſince Almighty God has been pleaſ'd to Implant thoſe Original Principles in us, by which we are Diſpos'd to acquire all our Good or Ill-Qualities from the Contractive and Expanſive, and at the ſame Time has Endu'd us with a Faculty and Power to determine our ſelves to the one or the other; but leſt this Faculty and Power ſhou'd be Ill-Imploy'd by us, that is, leſt the Principles of Natural Religion ſhou'd not Sway and Incline us to that which is Good, he has alſo given us a Reveal'd one, whoſe Doctrines and Precepts tend the ſame Way with the Contractive Force of our own Minds, which is to Incline them to all the Vertuous Affections and Properties of our Natures, which are Contrary to the Expanſive and Repulſive of them, and which fall in with Love and Benevolence, Charity and Goodneſs, and all the Contractive Forces which belong to them.

Why Sobriety of Thought and Judgement prevails againſt Gaiety and Wit.

§. 27. Let us farther Conſider, what theſe Expanſive and Contractive Forces of the Mind are Abſtracted from Morality, or the Vertuous and Vitious Inclinations it Poſſeſſes, and we ſhall ſtill find the ſame Law of Nature obtains; Thus Memory, Recollection, Wit, and a Quickneſs of Thought and Apprehenſion is deriv'd from the Expanſive Force of the Mind, as Perception, Judgment, Reaſoning, and Solidity is owing to the Contractive Force of it; for in the firſt, we may obſerve a kind of Elaſticity in the Production of our Ideas, and a Volatility as well as Incoherence of them, and in the ſecond a Contraction by their Cloſeneſs, Connexion, and Gravity; and as in the other Caſes, ſo in this, the Mind, when it is Agitated betwixt theſe Two Forces, is in a ſort of Conteſt with it ſelf, and uneaſy, till it is ſettled in the Contractive.

Why Men of Wit are Inclin'd to Vice, and Men of Judgment to Vertue.

We may farther take Notice here, that as we have made the Vitious Propenſities of our Minds to be chiefly deriv'd from the Expanſive Force, and the Vertuous from the Contractive, and Memory, Wit, Quickneſs and Gaiety of Thought to be the Reſult of the Former Force, and Judgment or Reaſoning the Effect of the Latter, ſo we likewiſe in Fact and Experience find, that thoſe who are the Wittieſt and the Gaieſt are generally the moſt likely to be carry'd into Vice, and thoſe who are of the beſt Reaſon and Judgment to be determin'd to Vertue, and in Conſequence of it to Religion, which is the Grand Promotor and Aſſertor of it.

How the Mind is united to Matter, and yet Diſtinct from it.

§. 28. I wou'd not be here thought to make the Nature of the Mind to conſiſt in the Expanſive and Contractive Forces, or Action in General, ſince That we have ſaid is the Eſſence of Matter, and which will ſolve all the Phænomenons and Senſations we perceive from it, but Action will not give a Solution of Thought and Intelligence; we therefore affirm the Mind to be a Thinking Immaterial Subſtance, to which yet there are a certain Kind of Expanſive and Contractive Forces belonging, and which are Indications and Characteriſticks of the Genius and Temper of the Mind, in which they Reſide, and by the Intervention of which Forces it ſeems Probable, that it is united with Matter.

How the foregoing Law of Nature is juſtify'd by the Union of the Mind with Matter.

§. 29. To which, if we now Extend this Law, that is, to the Union of the Mind with the Body, we ſhall find it ſtill the ſame; for thus whilſt the Mind and Body are in their Natural State, the Contractive Force of the Mind joins it with the Contractive of Matter, and the Expanſive of the Mind, being in an Æquilibrium with the ſame Contractive of Matter, continually keeps the Fluids in Motion, and Circulates the Blood and Spirits, and all other the Juices, which are Requiſite to the Animal Oeconomy.

The Cauſe of Lethargies, Comas, Jaundice, Dropſies, &c.

But Firſt, If the Contractive of Matter is too Powerful for the Expanſive of the Mind, the Æquilibrium is broken, and the Expanſive of the Mind ſinks beneath the Contractive of the Body, as in Lethargies, Comas, Jaundice, and Dropſies, and the other Diſtempers, which proceed from a Viſcidity, Flaccidneſs, Thickneſs or Languor of the Blood and Serum, or too Great a Quantity of them, whilſt yet the Contractive of the Mind remains, by which it can Reaſon, Perceive, and Judge as at other Times; ſo that the very ſame Principle, namely an Æquilibrium betwixt the Expanſive and Contractive Force, which ſolves the Revolutions in the Heavenly Syſtem, accounts likewiſe for the Circulation of the Blood and the other Fluids in a Human one, excepting that there it is the Expanſive and Contractive Force of Matter, whereas here it is the Expanſive of the Mind or of the Juices of the Body, which is Analogous to it, and the Contractive of Matter;

The Cauſe of Fevers and Phrenzy.

Second, If the Expanſive of Matter is too Powerful for the Expanſive of the Mind, the Contractive of the Mind ſtill continues, ſo far as to preſerve it's Union with the Body, but is diſturb'd by the Superior Expanſive of Matter joining with the Expanſive of the Mind, from whence an Extreme Volatility and Diſſipation of Thought ariſes, an Incoherence of Ideas, and a ſurprizing Quickneſs in their Motion, as in Drinking Spirituous Liquors, in Fevers, and in a Phrenzy: And in both theſe Caſes, when the Contractive Force of Matter in the Firſt is too Great, and the Expanſive Force in the Laſt, the Mind Reſults from the Body, a Diſſolution of the Union Enſues, and it Departs with it's own proper Expanſive and Contractive Forces from the Body, which it had hitherto Actuated and Inform'd;

The Cauſe of Melancholy.

Third, If the Contractive Force of the Mind by any Ways or Means is ſo far Increas'd, as to break the Æquilibrium betwixt the Forces of the Mind and of Matter, as by Great and Intenſe Study, by an Extreme Concern for the Good of others, by Afflictions in the Cauſe of Religion and Vertue, or too Mighty a Zeal, Concern, and Sollicitude for them, which we have ſhewn are all of a Contractive Nature, the Mind may be caſt into a Depth of Melancholy, and tho' it's Reaſoning and Judgment is ſtill Preſerv'd, the Body may be brought into an Ill and Languid State, and the Mind grow Heavy, Dull, and Unactive.

The Cauſe of Madneſs and Diſtraction.

Lastly, If the Expanſive Force of the Mind is likewiſe Increas'd beyond an Æquilibrium with the Forces of Matter in the Body, by too Exceſſive a Pride, Covetouſneſs, Ambition, Revenge or Cruelty, which are of an Expanſive and Repulſive Force, or by any other Vices of the like Selfiſh Complexion, a too Great Expanſion ariſes in the Mind, and by Conſequence a Madneſs and Diſtraction, by which the Ideas of it are Interrupted and Incoherent, Acquire an Exceeding Swiftneſs and Velocity, and the Fluids of the Body are put into a Wild Ferment, and the Whole Maſs and Compoſition into the Higheſt Diſorder, and from hence Anger and Fury, which owes it's Origine to theſe Expanſive Qualities of the Mind, has been juſtly Term'd and Eſteem'd a ſhort Madneſs.

How Good Men are Happy after Death, and Ill Men Miſerable.

In theſe Two laſt Caſes, if the Diſturbance is very Great, the Union betwixt the Mind and Body is Diſſolv'd, and Melancholy or Madneſs Equally deſtroy the Harmony betwixt both, whilſt the Mind departs Compos'd and Satisfy'd in the Firſt Caſe, and in the Laſt, Roil'd and Uneaſy, Full of Wretchedneſs, Pain, Anxiety, and Miſery. But whilſt the Mind and Matter continue United, it is more Difficult to Cure the Former Diſturbance of the Æquilibrium than the Latter, becauſe it is harder to Raiſe a Contractive Force into an Expanſive, than to Depreſs an Expanſive to a Contractive, ſince, all the Expanſive Forces, of what kind ſoever in the Earth we Inhabit, bear a very ſmall Proportion to the Contractive, and for which Reaſon we ſaid, tho' there might be a Perpetual Quieſcence, there cou'd not be a Perpetual Motion; thus likewiſe all Animate Beings are but few in Proportion to the Inanimate, and the Aſſiſtances in Nature to the Raiſing the Contractive Force into the Expanſive, are much Fewer than thoſe which we have to Depreſs the Expanſive to the Contractive; And from hence, it is much Eaſier to Extinguiſh a ſmall Fire, than to Throw into Fumes and Vapour a like Quantity of Water.

Why Melancholy more Difficult to Cure than Madneſs.

Concerning the Diſtempers Incident to this Union, and the Rational Methods of Curing them in Conſequence of this Law.

§. 30. From what we have alledg'd, it may be eaſily Infer'd, that, in theſe Four Caſes, there are Different Ways in Phyſick to be purſu'd to Reſtore the Æquilibrium, and that the Forces of the Mind, in all Preſcriptions in that Science, ought to be as Carefully, and Punctually Examin'd and Attended to, as thoſe of the Blood or of the Fluids of the Body;

In the Firſt, the Chief Intention ought to be to Raiſe the Expanſive Force of the Blood and Animal Juices, by Spirituous Liquors moderately us'd, or by Exerciſe, or by a Diminution of the Quantity of them by Abſtinence, or by all of them together;

In the Second, the Principal Intention ſhou'd be to Depreſs the Expanſive Force of them, by Cooling and Contractive Medicines, and by a Regular and Thin Diet, and all other Methods, which are Fitted to Allay the Heat and Efferveſcence of the Blood and Animal Juices;

In the Third, Medicines will be of little Force, but Action, Mirth, and Company, and all the Innocent Diverſions of Muſick, and the Agreeable Entertainments of Wit and Gaiety, will prove the moſt Effectual to raiſe the Contractive Force of the Mind into a juſt Expanſive; and Riding and Travelling into Diſtant and New Scenes is not a little Conducive to the ſame End.

In the Laſt, Precepts of Vertue and Religion, and the Impreſſions of Reaſon, Sobriety, and Judgment, and Exerciſing the Mind in that Way, will in all Probability have more Influence, than all the Drugs which can poſſibly be Invented or Preſcrib'd; and I have ſometimes thought, that the Chriſtian Religion, which, as we have ſhewn, is of a Contractive Nature, may probably have as Real and Neceſſary an Effect in Curing Demoniacks, or in theſe latter Ages Madmen, as it has had in Reducing Men from Vice, Immorality, Ill-Nature, and Extravagance, which likewiſe, as Madneſs, are of an Expanſive Nature, to Sobriety, Vertue and Goodneſs, which are of a Contractive one.

How the Mind is Diſtinct from the Body, and will Survive it.

From all which we may reaſonably Conclude, that as there are theſe ſeveral Maladies Incident to our Natures, which have Diſtinct Origins, ſo that the Mind is a Subſtance Different from the Body, and which will Survive it; ſince, according to this Law, which we have Evinc'd to be a General one in Nature, where one Force prevails againſt another, the Force, which ſubmits, is not Deſtroy'd or Annull'd, but ſtill continues; and as it is Evident, that an Expanſive and Contractive Force of Matter is preſerv'd even to the Body diſſolv'd from the Mind, ſo it is Equally Rational to think, that the Expanſive and Contractive Force of the Mind is Conſtant and Permanent upon it's Diſſolution from the Body; beſides which, the Contractive Force of the Mind, it's Reaſoning and Judgment, is not much Affected by the Contractive Force of the Body being too Great, as in the firſt Caſe; in the Second, it is, by the Expanſive Force being ſo, of which therefore when it is acquitted by a Diſſolution from it, it muſt be unaffected by it; in the third Caſe, the Contractive of the Mind is Increas'd, and in the laſt, the Expanſive; from whence it is Manifeſt, that the Forces of the Mind in any of theſe Caſes are not, nor can be Diminiſh'd, much leſs Annihilated by it's Separation and Diſſolution from the Matter, with which it is United.

The Nature of Dreams, and the Reaſon of Them.

In the Union of the Mind with the Body, we ſhall only farther Inſtance in Dreams, that in a Natural State, where the Forces of the Mind and of Matter are in an Æquilibrium, the Blood and Fluids circulate Regularly, and Various Ideas are Exhibited to the Mind, according to the Various Temper, Craſis, or Action of ſuch Fluids, as they paſs thro' the Brain, the Place of the Mind's Reſidence; but if the Contractive Force of the Blood and Juices is Increas'd beyond the Natural State, if they become Colder and Chiller than ordinary, Repreſentations of Water are produc'd, as in ſome ſmaller Degrees of Melancholy, if the Expanſive is Increas'd, as in Fevers, they Change into thoſe of Fire; In the firſt Caſe, the Mind is more Compos'd, and in the laſt, more Diſturb'd and Uneaſy, and the Images in the Mind carry an Analogy with the Expanſive or Contractive Forces of the Blood and Fluids, which Impreſs them; and our not Dreaming ſometimes at all ſeems to ariſe from the Contractive Force of the Blood and Fluids being too Powerful for the Forces of the Mind, ſo long as it is united with them, as in an Exceſs of Eating, or from too Great a Quantity of the Expanſive, as in taking in too Much of Spirituous Liquors, both which Oppreſs and Over-turn the Forces of the Mind for the Time, that is, During the Union of the Mind with Matter; and if the Exceſs is carry'd to too Great a Degree, the Mind, when it cannot over-come, Reſults and Rebounds from theſe Forces, by which it is Diſunited and Separated from them.

Concerning the Diſtempers Incident to the Body conſider'd by this Law; with the Cauſes of Colds, Agues, Small-Pox, Fevers, and Peſtilence.

§. 31. If we now conſider the Body it ſelf, we ſhall find it Incident to thoſe Diſtempers, which cou'd not be otherwiſe Accounted for, than upon this Law and the Forces of it; for how comes it to paſs that Fevers, Colds, and Agues are the Common Ailments in theſe Climates, whilſt in Hotter ones Plagues and the moſt Peſtilential Diſtempers are the Produce of them? And why is the Small Pox in Particular almoſt every where Allotted to our Natures, unleſs in Countries of the moſt Exceſſive Heats? Fevers are Evidently from too Great an Expanſive Force in our Blood and Juices, and Colds from too Great a Contractive one, and in Agues there is a Reciprocation of and a Conteſt betwixt both; and it is no Wonder in our

Climate, where theſe Principles of the Expanſive and Contractive prevail in their Turns, in Summer and Winter, that they ſhou'd Induce the ſame Qualities and Properties into the Blood and Fluids, and by Conſequence Excite Fevers, or Impreſs a Chillneſs, a Damp and Cold upon them; and as in Spring and Autumn, the Expanſive and Contractive are in a kind of Conflict by the Winds and Tempeſts we obſerve at thoſe Times, ſo it is not ſtrange that ſuch an Effect is Propagated to the Fluids of the Body, and that Agues are caus'd, in which the Expanſive and Contractive Forces in the Blood and Juices Reciprocally Triumph and Yield; But that which occaſions the Original Diſturbance and Diſorder, in this laſt Diſtemper, is the Contractive, as Agues proceed from Cold, and the Burning Fit, Experience't in them, ariſes from the Exaſperation of the Expanſive by the Oppoſition of the Contractive, which we have Evidenc'd is the Law of theſe Forces, and therefore the Hot Paroxyſm ſucceeds the Cold one, as is known.

How the Bark of Peru, *and other Medicines Operate in the Cure of Aguiſh Diſtempers.*

THE Way therefore to Prevent or to Cure ſuch Aguiſh Diſtempers is to Aſſiſt the Expanſive either to Repel the Contractive before it's Admiſſion into the Blood and Juices, or to Drive it out afterwards, which is done by Riding and Exerciſe, by Hot Vegetables, Roots, and Herbs, by Bitters, and eſpecially by the Bark of *Peru*, or other Barks of a like Nature, and by a Moderate uſe of the moſt Spirituous Liquors, all which have an Expanſive Force, and tend to the ſubduing of the Contractive; and this ſeems to be the real Method, by which the ſaid Bark Operates, which, if ſo, will be a Confutation of a Thouſand Fancies concerning it, and it's Power of Locking up Pores, or Abſorbing the Febrifick Matter, and of doing Many more Feats of Activity, which no one ever Dream't of, Except the Phyſician or the Philoſopher; but above all, an Employment of the Mind in all the Senſations and Faculties of it, and Raiſing it's Expanſive by Study, or by Wit and Diverſion, or any Way, which is the moſt Agreeable to it, ſeems to Carry the Greateſt Force towards the ſubduing the Contractive of the Blood and Fluids of this Diſtemper.

Why not to be Given in the Paroxyſm.

FROM hence it is alſo Evident, that theſe Remedies are not to be apply'd in the Paroxyſm it ſelf, becauſe, when the Contractive is in it's full Power, the Expanſive will only add to it's Triumphs, and render it more Pertinacious and Obſtinate to be Over-comn according to the preſent Law; that is, the Conteſt will be the Greater by an Addition of the Expanſive, in like Manner, as the more Expanſive Force we give to the String or ſtretch'd Wire, whilſt the Contractive Force continues fixt at the Centers of the Tenſion, the ſtronger will be the Vibrations betwixt the Expanſive and Contractive; Beſides which, ſince the Expanſive Force is the Cauſe of Digeſtion, and ſince any Aliments, which we take in, are in ſome Meaſure of a Contractive Nature, that is ſuch, as want to be Digeſted, and ſince the Expanſive Force always Acts in Oppoſition to the Contractive, the Expanſive Force in the Animal Oeconomy is weaken'd, and taken off from ſubduing the Contractive of the Blood and Juices, by Exerting it ſelf in the Digeſtion of the Aliment or Medicine Receiv'd.

Why Agues in Spring more Eaſily Cur'd than Thoſe in Autumn.

WE muſt likewiſe ſay, from hence it may be Infer'd, which, as the Phænomenons before, no Philoſophy has yet Accounted for, that an Ague, which conſiſts in a Conteſt betwixt theſe Expanſive and Contractive Forces, is more eaſily Cur'd, when it begins in the Spring than in the Autumn; becauſe the Expanſive Force in the Summer, Experience't from the Sun's Rays, very much Contributes to the ſubduing of the Contractive Force, whereas the Contractive Force of the Winter-Colds ſupports and continues that of the Blood and Juices, and conſequently falls on the Side of the Force, which wants to be Vanquiſh'd and Subdu'd.

Why Riding and Exerciſe Beneficial in Colds and Conſumptions.

THUS alſo in Colds and Catarrhs the Contractive Force Prevails in the Blood and Fluids, and Requires the Expanſive of Riding and Exerciſe, and a Moderate uſe of Spirituous and Warm Liquors to Diſſipate and Diſſolve it; and if, notwithſtanding, the Contractive Increaſes, a Conſumption many Times enſues, and a Languor and Inactivity is Induc'd upon the Blood and Juices; Nature ſinks and droops, by means of the Contractive, and a Hectick, or ſlow and ſilent Fever accompanies the Diſorder; becauſe there is a continual Conteſt betwixt the Contractive, which ſpreads it ſelf all over the Body, and the Expanſive of the Blood and Fluids, by which they Circulate; and conſequently Soft and Warm Liquors, as Aſſes Milk, which are Nouriſhing and Contribute to the Expanſive, as alſo Gentle Riding and Exerciſe, are alike Beneficial, as in Colds.

Wherein the Difficulty of Phyſick Lies.

IT muſt here be Obſerv'd, that when the Intention is to Conquer and Surmount the Contractive, the Expanſive muſt be Proportion'd in ſome Meaſure to it, and the ſame may be ſaid of the Contractive, when the Expanſive is to be Curb'd and Allay'd, and herein ſeems to conſiſt the chief Skill in Phyſick, Namely, Firſt, to know of what Nature and Degree the Expanſive or Contractive Force is, which is to be Reduc'd into Order, which requires the Sagacity and Penetration of one well vers'd in the ſeveral Diagnoſticks of Diſtempers Incident to the Human Frame and Compages; and Second, to be fully Acquainted with the Expanſive and Contractive Forces of Medicines, and to be Able to Determine what Degree of the Expanſive or Contractive Force is Proper to be Apply'd upon the Preſent Emergence.

THUS in Agues, where the Contractive Force is Great, as is Evident by it's Shaking the whole Animal Syſtem, and Obtaining the ſame Effect in the Blood and Fluids, as an Extreme Cold in the outward Parts of the Body, Strong Bitters, and Spirituous Liquors are found Neceſſary, which, in a Conſumption, wou'd be Prejudicial, where the Contractive being leſs is to be prevail'd upon by more Gentle Expanſives and Milder Applications; for ſo a vaſt Weight is to be Remov'd by a Prodigious Degree of Velocity, which, if Apply'd to a Smaller, wou'd produce an Exceſſive Velocity likewiſe, and, in the Animal Syſtem, ſo Great a one, as might Endanger the Diſſolution of it, as much as the Contractive will, if not ſubdu'd, Depreſs and Sink it.

From whence Fevers and Peſtilential Diſtempers, and How Cur'd.

ON the Contrary, Fevers and Peſtilential Diſtempers ariſe from the Prevalence of the Expanſive, and are the Natives of Hot Seaſons and Countries, and therefore it is Reaſonable to Think, that Cold and Contractive Medicines are what we ſhou'd have Principally Recourſe to in ſuch Caſes, as Water, Lemmons, *&c.* but this is to be done with ſome Prudence and Caution, becauſe, if a Contractive Force is added to the Blood from ſuch Applications, the Fever may be Increas'd by Exciting and Exaſperating the Expanſive, which always acts in Oppoſition to the Contractive, and conſequently it may not be Improper to Infuſe theſe Contractive Forces into the Blood with a Mixture of the Expanſive. And ſince the Writing of this I find, that *Aromatick Acids* were of the Greateſt Service at the Plague of *Marſeilles.*

Why the Small-Pox a General Diſtemper Excepting in Hot Countries.

THE Small-Pox manifeſtly is deriv'd from a Prevalence of the Contractive, and conſequently, Cordials and Spirituous Liquors, which are of an Expanſive Force, if Nature cannot do it, are Aſſiſtant to the Expelling of it; Every one is Subject to this Diſtemper, becauſe Every one has more of the Contractive than the Expanſive, in his Blood, excepting in Exceeding Hot Countries, where the Expanſive prevails, and for the ſame Reaſon Some never have Them.

Concerning other Animate Beings, and the Expanſive and Contractive Forces of them.

§. 32. LET us now Deſcend to the Creatures, which are below us, and amongſt thoſe, whoſe Senſes have moſt of the Expanſive Force, we may reckon the Volatile Kind, and amongſt thoſe, whoſe Senſes have moſt of the Contractive, the Aquatick; the one Inhabiting that Elaſtick Medium, the Air, and the other the Phlegmatick one of Water, from each of which their Senſitive Faculties derive their ſeveral Tinctures, and from whence we find the utmoſt Life, Quickneſs, and Vivacity, and almoſt even Wit and Humour in the Former, and in the Latter, an Eminent Torpor and Dullneſs; in the Land-Animals likewiſe, which partake of Earth, Air, and Water, we ſee a Degree of Senſe ſomething Intermediate to them both; And by the ſame Method we might Diſtinguiſh all the Sundry Species of Animals from each other, by their Expanſive and Contractive Forces, but it is at preſent ſufficient for us to ſhew, that theſe Forces obtain and prevail in all Nature, and that the Law of 'em before mention'd is Eſtabliſh'd in the ſeveral Beings of it.

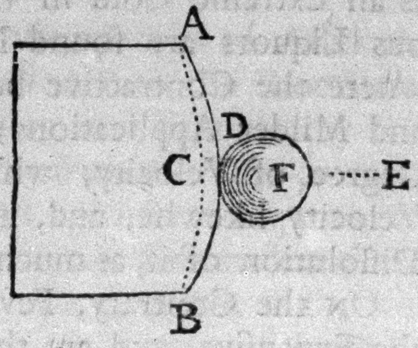
From whence is Concluded the Infinite Superiority of the Human Syſtem, and the Immortality of the Soul.

§. 33. WHAT therefore we ſhall farther ſay here is only This, that the Great Diſtinction betwixt Human Minds and the Senſitive Faculties of Animals is, that the Firſt have a Contractive Force by which they Reaſon and Judge, whereas the Laſt, at the Moſt, have only an Expanſive in the Compariſon; that is, their Faculties are ſuch, from which Ideas are ſtruck out by the Expanſiveneſs or Elaſticity of them, and by the ſame Force remember'd, but are not ſtrong enough to Retain thoſe Ideas, ſo as to Reaſon, Conſider, and Judge of Them; The Mind therefore has a Force Infinitely Superior to theſe Small and Momentany Vibrations of the Faculties of other Animals, and conſequently Infinitely more Durable and Laſting, as the Vibrations of the Heavenly Bodies upon their Center, that is, their Revolutions round it, are more Permanent than the Oſcillations of the Wire of a Virginal, or as the Solid Strokes of the

the Expanſive of Marble or Gold upon the Æthereal and Elaſtick Plenum are of a more Eternal Nature, (for, unleſs thoſe Subſtances are Annihilated, thoſe Pulſes will always Remain and Continue), than the Temporary Glances of the Expanſive Force of a Glow-Worm, or of the Flaſhes of Lightening; and it is from theſe Grand and Noble, theſe Strong, Sublime, and Magnificent Forces of the Mind, that is, from the Contractive, by which it is Capable of Reaſon, Morality, Vertue, and Religion, of which no other Beings are, that we may juſtly Conclude it's Immortality, whilſt it's Expanſive is Common to it, in ſome Meaſure and Degree, with other Animate and Senſitive Creatures.

The Modern Doctrine of Elaſticity, as apply'd to Natural Bodies Explain'd and Examin'd.

§. 34. Having thus Finiſh'd what we Intended at preſent to propoſe concerning this Law of Nature and of the Expanſive and Contractive Forces, we ſhall Return to our Examination of the Modern Doctrine of Elaſticity; in Order to Explain which in Natural Bodies, the Surface *ADB* is ſuppos'd to be Compreſs'd, by the Incurring Body *F*, Inwards to *ACB*, and by the *Vis Reſtitutiva* to be Reſtor'd to it's Firſt Situation in *D*, with the ſame Celerity with which it is Compreſs'd, if the Bodies are perfectly Elaſtick; But we ſhall ſee now the Shortneſs and Defectiveneſs of ſuch Principles, as well as the Falſhood and Untruth of them;



For Firſt, the *Vis Reſtitutiva*, as we have ſhewn, is an Imaginary Thing, and has no Foundation in Nature for it's Support, ſince the Inſtance of the String or a Wire, Stretch'd betwixt two Fixt and Immoveable Points, is no Proof or Eviction of it;

Second, Granting this *Vis Reſtitutiva*, by the foregoing Explanation of it from a ſtretch'd Wire or String, the Surface *ADB* ought to be Compreſs'd to *ACB*, by the Incurring Body *F*, the *Vis Reſtitutiva* ought likewiſe to reſtore the Compreſs'd Surface to it's Former Situation in *D*, and by the Velocity acquir'd to go beyond it towards *E*, then the *Vis Reſtitutiva* is to draw it back from thence to *D*, and by the Velocity acquir'd, the Surface is again to be carry'd towards *C*, and ſo Alternately the Progreſſes and Regreſſes of the Surface are to be perform'd, till it becomes Quieſcent in *D*; which if ſo, ſuppoſing any other Body, after the Repulſion of *F* to *E*, is Apply'd to the Surface *ADB* thus agitated, and ſuppoſing ſuch Body is barely Apply'd to it, without any Incurring Velocity, it muſt be in ſome Degree Repell'd from it towards *E*, and nearly with the ſame Force as *F* is, which is Contrary to all Fact and Experience;

Third, Granting likewiſe this Imaginary *Vis Reſtitutiva*, by which the Surface *ADB*, when Compreſs'd by the Incurring Velocity to *ACB*, Reſults with the ſame from *C* to *D*, what wou'd be the Conſequence of it? not the Repulſion of *F* from *D* to *E*, but from *C* to *D*, which wou'd prove a very ſlender Account of the Reflection of Bodies at ſeveral Diſtances from the Surfaces, on which they Incurr'd, when, by this, they wou'd not recede one Tittle from them;

Fourth, As to the Experiment, which is made uſe of to Confirm this Compreſſion of the Surfaces of Bodies and the Reſtitution of them to their Firſt Situation, namely, that if you take Two Globes of Glaſs or Ivory, and Paint the Quieſcent one with Ink or any other Colour, and let the Impingent one fall upon it, the Impingent Globe will be Colour'd in a Broad Spot, tho', according to the Nature of Spherical Figures, It ought only to be Ting'd or Colour'd in a Single Point; The Reaſon of which Broad Spot upon the Impingent Globe is thought therefore to be this, that the Surface of the Quieſcent Body is Compreſs'd upon Impaction, and conſequently, that the Impingent is by that means Colour'd in a larger Circuit, than otherwiſe it wou'd be, but ſince we find the Body, upon which the Impaction is made, ſtill Spherical after ſuch Concourſe and Compreſſion, it muſt have Reſtor'd it's Surface to it's former Situation; As to This Experiment We ſay;

That It by no means proves the *Vis Reſtitutiva*, or the Compreſſion of the Surface, for which it is alledg'd; Becauſe it is not Evinc'd, that this Broad Spot of Ink, which is Impreſs'd upon the Impinging Globe, may not be cauſ'd by an Electricity or Attraction of the Impingent to a certain Circuit, or by a Repulſive Force in the Globe upon which the Impaction is made, which Qualities may be

Excited in the one or the other by the mutual Action betwixt them; it being moreover a known Fact, that a Body falling upon a Fluid, as the Ink here is ſuppos'd to be, Daſhes it in a Circuit upwards, and makes it Riſe towards the Body which is the Aggreſſor, and ſeems to be owing to the Law before mention'd, where the Contractive of the Ink acts in Oppoſition and Contrary to the Expanſive of the Incurring Velocity.

It may yet be Diſputed, whether this Experiment will ſucceed in all Elaſtick Bodies, for by what Trials I have made, it do's not betwixt Two Globes of Marble; and conſequently, if ſo, there may be an Elaſticity, where there is no Alteration of the Surface, and therefore no *Vis Reſtitutiva* in it, and which can be no other ways accounted for, than by the Expanſive Forces Reſident in Bodies in Various Proportions and Degrees, according to what we have already Mention'd and Explain'd.

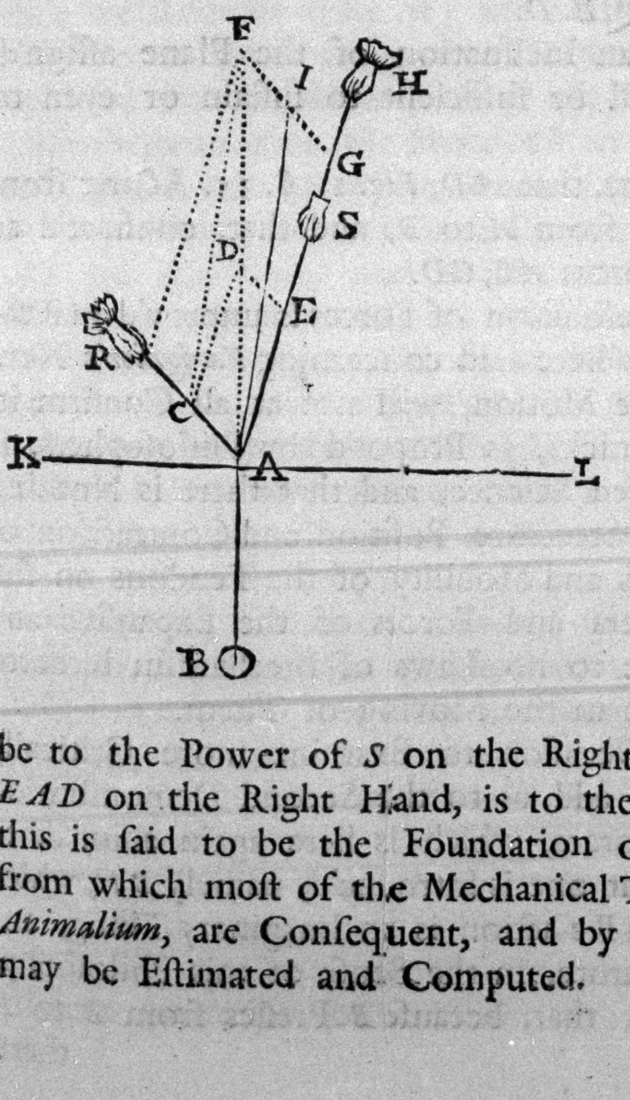
Fifth, As to what is urg'd againſt the *Carteſians*, who make Elaſticity or the Reflection of Bodies to conſiſt in the Continuation of the ſame Motion, tho' in an oppoſite Direction, it is a ſufficient Confutation of ſuch a Fancy to ſhew them, that according to them, all Bodies upon Impaction ought to be Reflected, whereas in Fact and Experience ſome Bodies are not, as thoſe which are Eſteem'd to be Unelaſtick; but at the ſame Time it is no Confirmation of the Preſent Doctrine, which Introduces a Compreſſion of Surfaces and a *Vis Reſtitutiva* of them, as much unknown in Nature, and which has as little Foundation in it, as the Continuation of Motion, where no Motion is Continu'd.

Sixth, From hence therefore all which is ſaid, in Theorem the *29th*, That if Two Bodies perfectly Elaſtick Impinge upon each other, their Relative Velocity before and after Impaction will remain the ſame, that is, after Concourſe, that they will retire from each other with the ſame Celerity with which they approach'd, is without any Grounds in Nature and Fact, it is an Abſtracting Reaſoning, and all the Rules of Congreſs determin'd from thence, in Problem the *3d*, and the Algebraick Calculations form'd thereupon, are mere Notions and Chimeras, as are alſo Theorem 31, 32. and Problem 4.

See §. 11, 12, 13.

Dr. Keill's Introduct. Lect. 14.

§. 35. The next Doctrine we ſhall Enquire into in this Philoſophy, is concerning the Forces and Powers of Bodies, which act againſt each other, ſo as to produce an Æquilibrium in them. Let B be a Weight ſupported by Two Powers R and S, which draw it, by the Mediation of Two Strings, according to the Right Lines AR and AS; The Point A is conſequently urg'd by Three Powers, Two of which act in the Direction of AR and AS, and the Third is the Force of Gravity in B, Tending in the Right Line AB Perpendicular to the Earth; The Power R on the Left Hand will be to the Force of Gravity, as AC to AD, or, as the Sine of the Angle DAE on the Right Hand to the Sine of the Angle CAE, comprehended betwixt both the Forces, and = to AB the Repreſentation of the whole Force; and the Power S on the Right Hand will be to the Force of Gravity, as EA to AD, or, as the Sine of the Angle CAD on the Left Hand, to the Sine of the Angle CAE, comprehended betwixt both the Forces, = AB the Repreſentation of the whole Force; and the Power of R on the Left Hand, will be to the Power of S on the Right Hand Reciprocally, as the Sine of the Angle EAD on the Right Hand, is to the Sine of the Angle CAD on the Left; And this is ſaid to be the Foundation of the New Mechanicks Publiſh'd by *Varignion*, from which moſt of the Mechanical Theorems, contain'd in *Borellus*'s Treatiſe *de Motu Animalium*, are Conſequent, and by which the Forces and Powers of the Muſcles may be Eſtimated and Computed.



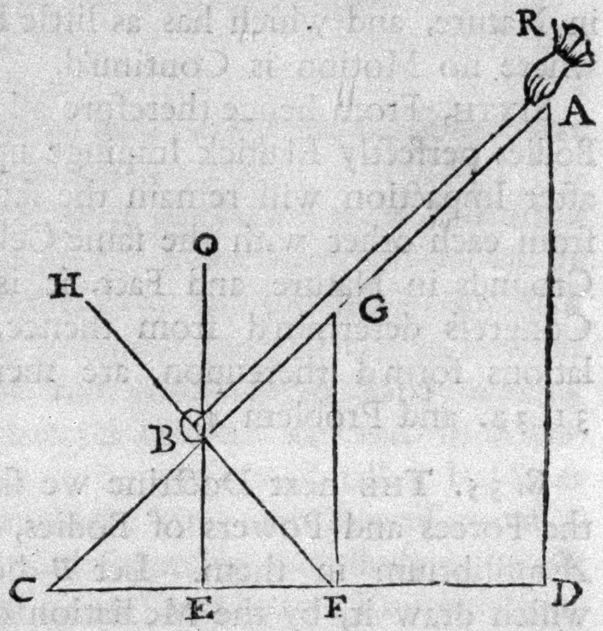
Concerning the Powers of Bodies Drawing againſt each other, and in oppoſite Directions.

Dr. Keill's Intr. ad Ver. Phyſ Lect. 14. Theorem 33. and 34. and Corollaries.

THE Demonſtration of which Theorem is upon this Suppoſition, that *AD*, Acting from *A* to *D*, is Equal to the Force of Gravity in *B*, and which is Repreſented by *AB*, and that *AD* the Diagonal Force is Reſolv'd into the Lateral *AC*, *CD*, but ſince, in every Triangle, the Sides are as the Sines of the Angles oppos'd to thoſe Sides, $AC.CD = AE$:: Sine of the Angle $ADC = DAE$. Sine of the Angle *DAC*; from whence it follows, that any Two Powers will be to each other Reciprocally, as the Sines of the Angles, which the Lines of the Directions contain with the Line of Direction of the Third Power; Moreover *AD*.*AC*:: Sine of the Angle *DCA*, or it's Complement $DCR = CAE$. Sine of the Angle $CDA = DAE$; and in like Manner, the Power Acting according to the Right Line $AB = AD.AE$:: Sine of the Angle *CAE*. Sine of the Angle $ADE = CAD$. *Q. E. D.*

AFTER this comes Theorem the 34*th*, which affirms, That if a Heavy Body *B* is Incumbent upon an Inclin'd Plane, and is ſupported and kept from Deſcending by a Power *R*, which acts Parallel to the ſaid Plane, the Power *R* will be to the Weight of the Body *B*, as the Sine of the Angle of Inclination to the Radius, or *R*.*B*::*AD*.*AC*.

FOR *B* is acted or urg'd by Three Powers, from *B* towards *E* by it's Gravity, from *B* towards *A* by the Power *R*, and from *B* towards *H* by Re-action, ſince *B* Preſſes on the Plane *AC* towards *F*, and is therefore by Re-action Repreſs'd towards *H* in a Line Perpendicular to the Plane; Conſequently, if we Draw the Line *OB*, we ſhall have the Caſe of the Preceding Theorem, where Three Powers act againſt each other ſo, as to produce a Quieſcence or an Æquilibrium in *B*; and *R* the Power on the Right Hand is to *B* the whole Force or Sum of the Forces, as the Sine of the Angle on the Left Hand *HBO* is to the Sine of the Angle Comprehended betwixt both the Forces *HBR*, that is, as *BG* to *GF*; for *BG* is the Sine of the Angle $BFG =$ to the Angle *HBO*, becauſe *FG* and *BO* are Parallel, alſo *FG* is the Sine of the Angle *GBF*, which is a Right one = to the Angle *HBR*, But by 8. Elem. 6. *BG*.*FG*::*FG*.*GC*, by 4. Elem. 6, ::*AD*.*AC*, and therefore *R*.*B*::*AD*.*AC*. *Q. E. D.*



Hence it follows, That there may be ſuch an Inclination of the Plane aſſign'd, that, upon it, the leaſt Power Imaginable ſhall be ſufficient to ſuſtain or even to raiſe the Greateſt Weight whatſoever.

The Preceding Doctrine Examin'd.

§. 36. THE foregoing Demonſtrations preſume, that *AD*, *Fig*. 1. §. 35. Acting from *A* to *D*, is Equal to *AB*, or to a Force Acting from *A* to *B*, and that, conſider'd as a Diagonal, it is Reſolvible into the Lateral Forces *AC*, *CD*.

BUT we ſhall afterwards ſhew, that ſuch a Reſolution of Forces is unprov'd in Reaſon, and unjuſtify'd by Experience, and what is here ſaid concerning *Varignion's* New Mechanicks, and *Borellus's* Account of Muſcular Motion, will not at all Confirm it, till it is Evinc'd, that the Doctrine of Mechanicks, as Propos'd by Philoſophers, is ſomething Real in Nature, and not an Abſtracted Science, and that there is Nothing more to be Conſider'd in the Muſcles, than the Structure, Poſition and Contraction of the Fibres on the one Hand, and the Paſſiveneſs and Mobility of the Tendons on the Other, and that there are not Certain Powers and Forces of the Expanſive and Contractive in the Mind, which are Reducible to no Laws of Mechaniſm hitherto Known, which have their Influence and Effect in the Moving of Them.

Borellus de Motu Animalium Propoſ. 4 & 7.

WE ſhall however poſſibly take another Occaſion to Examine more Critically into the Reaſonings of that Author, and only add, as to the Second Demonſtration here alledg'd, that beſides the Reſolution of Forces, which is here again aſſum'd, to make *B* conſiſt of Three Powers, a very Pleaſant one is Introduc'd, namely *BH*, which is ſuppos'd to be deriv'd from Re-action, which Re-action is an Imaginary Thing, and wants a Proof of it's Exiſting any where in Nature, in the Senſe of this Philoſophy; for farther, is it not very abſurd to Conclude, that, becauſe *B* Preſſes from *B* to *F*, therefore, and for that Reaſon it Preſſes from *B* to *H,* a Way which is the Direct Contrary? Not to Inſiſt, that it is altogether Inconceivable how *B* ſhou'd Preſs perpendicularly upon the Plane in the Direction *BF,* when by Confeſſion it Preſſes Obliquely upon it in the Direction *BE*; Since, if it's Force and Tendency is from *B* to *E,* I cannot have any Apprehenſion, how it's Force and Tendency ſhou'd be from *B* to *F,* and yet upon this Contradiction the Re-action *BH* depends.

Besides, If this Proportion is True, that *R.B::AD.AC,* if *AD* is = 0, or Infinitely Small, that is, if *AC* approaches Infinitely near to *CD,* the Force *R* will likewiſe be Infinitely Small, and therefore will be able to Support the Weight in *B,* and preſerve it in an Æquilibrium, and conſequently the leaſt Addition of Force will Move *B* towards *R,* or Elevate it, which is Impoſſible; for let *B* be a Hundred Pounds Weight of Lead, it can neither be ſtaid from Deſcending, if there is any Deſcent at all, by an Infinitely Small Force, nor much leſs can it be Rais'd towards *R,* but by a very Great one; which ſhews, that this Demonſtration is a Thing of mere Abſtraction, and *B* muſt not be conſider'd to have any Forces in it ſelf, but ſuch as *R* may Conquer in the Proportion of *AD* to *AC,* which is ſaying juſt Nothing at all, for by the Inſtance alledg'd it is Manifeſt, that when *AD* is Infinitely Small, and *R* is ſo, yet *B* ſhall Remain unaffected by it, and can neither be kept in an Æquilibrium nor be Elevated towards *R*.

But to Enquire a little farther into *Varignion*'s New Mechanicks, Let us conſider, that, Granting the Force *AD,* which acts in Oppoſition to *AB,* may be reſolv'd into *AC, CD,* and conſequently, that every Diagonal Force may be reſolv'd into it's Lateral ones, it is True, that according to this Reaſoning, *Fig.* 1. §. 35. the Force *AC*. Force *AE* :: Sine of the Angle *DAE*. Sine of the Angle *DAC*; and if the Force to be ſupported in *B* is ſtill Greater, and *AF* is an Oppoſite one Equal to it, *AR.AG*:: Sine of the Angle *DAE*. Sine of the Angle *DAC*; and therefore, *AC.AE::AR.AG,* or *AC.CD::AR.RF,* which is certain, by Elem. 6. But *AG, AR,* Acting at a Greater Diſtance from their Center *A,* than *AE, AC,* and in the ſame Inclination to *AD,* will be leſs Forces and will ſupport a leſs Weight in *B,* tho' they are here made the Repreſentations of Greater Forces, as *AF* is Greater than *AD*.

Thus it will be Harder to Raiſe the Body *B* to *A* at the Diſtance of *AL,* by a Force apply'd in *L,* than at the Diſtance *AK,* by a Force apply'd in *K*; that is, the Force of Raiſing Bodies is Increas'd in Proportion, as the Center of Action approaches Them, as the Force of Depreſſing Bodies in a Lever or Balance is Increas'd the farther we Remove from it; and conſequently *AE, AC* are Stronger Forces, and have a Power to Raiſe a Greater Weight in *A,* than *AG* and *AR* have, and yet *AG* and *AR* are the Repreſentatives of the Stronger Forces.

Supposing now the Force *AF* to be Reſolv'd into *AC, CF,* or *AC, AI,* it is Manifeſt, that ſince *AF* is the ſame, *AR, AG* ought to be Equivalent to *AC, AI,* which is Impoſſible; for *AC* is a Greater Force than *AR*, becauſe the Inclinations to *AF* are the ſame, and *R* acts at a Greater Diſtance from *A* than *C* do's, which Weakens and Enervates it; On the other Hand, *AI* is a Greater Force than *AG* is, becauſe, at much the ſame Diſtance of *I* and *G* from *A,* it acts nearer to *AF,* that is, in a perfect Oppoſition to *B,* for thus it is much Eaſier, that is, a Force has more Power, to Raiſe a Weight in *A* when it is apply'd Directly, than when Obliquely to it; if therefore *AC* is a Greater Force than *AR,* and *AI* than *AG,* it is Plain, that *AC, AI* cannot be Equal to *AR, AG,* and yet by this Doctrine they ought to be, being both Equal to *AF*.

Farther, *AE.AC*:: Sine of the Angle *CAD*. Sine of the Angle *DAE,* and *AI.AC*:: Sine of the Angle *CAD*. Sine of the Angle *IAF*; As therefore the Sine of the Angle *IAF* is Leſs in Compariſon with the Sine of the Angle *CAD,* than the Sine of the Angle *DAE* is, ſo ought *AC* to be Leſs in Compariſon with *AI* than with *AE,* that is, *AI* will be Greater than *AE*; and by the ſame Reaſoning and Enlarging the Angle *FAI,* till it comes to *FAG,* any Line betwixt *AI* and *AG* will Repreſent a Force Greater than *AE,* whereas we have ſhewn *AE* to be Greater in it's Force than *AG,* and yet *AG,* or the next Line to it, by what foregoes, will be in it's Force Greater than *AE,* which is Abſurd.

Lastly, If we conſider only the Fundamental Proportion of this Doctrine, that $AE . AC ::$ Sine of the Angle CAD. Sine of the Angle DAE, it will be liable to Objections; for as the Sine of the Angle CAD is Greater than the Sine of the Angle DAE, ſo AE muſt be Greater in it's Force than AC, which is not Evident; becauſe, tho' AC is more Oblique than AE in it's Action and therefore Weaker, yet Reciprocally C acts nearer to A, than E do's, and therefore upon that Account is Stronger; and conſequently AC and AE may be ſo diſpos'd in Reſpect of AD, if not in this Scheme, yet in an Aſſignable one, where the Obliquity of AC may be Compenſated by the Length of AE, in which Caſe, the Forces AC, AE may be Equal, notwithſtanding the Sine of the Angle DAE may be Leſs than the Sine of the Angle CAD.

CHAP. VII.

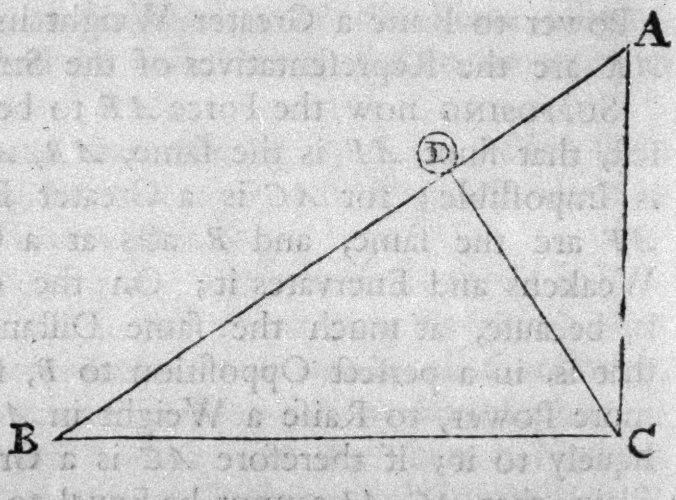
Concerning the Deſcent of Heavy Bodies in Inclin'd Planes, and the Oſcillation of Pendulums.

Concerning the Deſcent of Heavy Bodies in Inclin'd Planes. Theorem the Firſt. Dr. Keill's Intr. ad Ver. Phyſ. Lect. 15. Theorem 35. Hugen. Horolog. Oſcillator. Prop. 7. Par. 2.

§. 1. IN Order to Explain and Aſcertain this Doctrine, it is Suppos'd and Preſum'd, that the Force of Gravity is every where the Same and Alike, altho' in Different Diſtances from the Center of the Earth, it is ſaid to be Reciprocally Proportional to the Squares of the Diſtances; the Reaſon of which Suppoſition is, becauſe the Differences of the ſeveral Diſtances of Projectiles from the Center of the Earth are very Small and Inconſiderable in Compariſon with their Diſtances from the ſaid Center, and therefore may be Eſteem'd as Nothing. It is farther told us, that the Motion of Heavy Bodies is here ſuppos'd to be Perform'd, either in Planes Inclin'd to the Horizon, or in Curve Superficies, ſuch as Spherical and Cycloidical ones, and in Spaces perfectly Free and Unreſiſting.

And the Firſt Theorem in this Doctrine is, That the Deſcent of an Heavy Body upon any Inclin'd Plane is a Motion Equably Accelerated; Alſo, That the Velocity, which an Heavy Body, Falling down from it's Reſt upon an Inclin'd Plane, in any Given Time Acquires, is to the Velocity Acquir'd in the ſame Time, by an Heavy Body falling Perpendicularly, as the Height of the Plane to the Length of it. Let the Inclin'd Plane be AB, upon which let the Heavy Body D Deſcend;

First, by Corol. 1. Theorem 34, the Force, with which a Body endeavours to Deſcend upon any Inclin'd Plane, is to the Abſolute Force of Gravity, with which it wou'd Deſcend in a Perpendicular, in a Conſtant Reaſon of the Sine of the Inclination of the Plane to the Radius, or as the Height of the Plane to it's Length; and Conſequently, ſince the Abſolute Force of Gravity of the Body D continues the Same and Unalter'd, the Force will Remain the ſame, with which it Endeavours to Deſcend upon the Plane AB, That Force therefore will always act with the ſame Uniformity upon the Heavy Body D, and, by Law the Second, will continually ſuperadd Equal Increments of Velocities, in the ſame Manner, as is done in Heavy Bodies falling in a Perpendicular. From whence it follows, that the Deſcent of Heavy Bodies in an Inclin'd Plane is a Motion Uniformly or Equably Accelerated. *Q. E. D.*



Second, The Increments of the Velocities of Heavy Bodies, falling in a Perpendicular, and in an Inclin'd Plane, which are produc'd in the ſame Indefinitely ſmall Time, are to each other, as the Forces, by which they are produc'd, But the Forces are in a Conſtant Reaſon, namely, as the Length of the Plane AB to it's Height AC, and therefore the Increments of the Velocities, ariſing from thence, will be in the ſame Reaſon, and by 12. Elem. 5. the Sum alſo of the Increments of the one will be to the Sum of the Increments of the other, in the ſame Reaſon; that is, the Velocity of the Heavy Body falling in a Perpendicular is to the Velocity of an Heavy Body Deſcending, in the mean Time, upon an Inclin'd Plane, as the Length of the Plane to the Height of it. *Q. E. D.*

Corol. 1. THE Velocities of an Heavy Body falling in an Inclin'd Plane are as the Times, in which they are Acquir'd.

Corol. 2. WHATEVER has been Demonſtrated in Theorem 17. concerning a Motion uniformly Accelerated will be likewiſe True concerning the Deſcent of Bodies in Inclin'd Planes; Namely, That the Space deſcrib'd by an Heavy Body falling in an Inclin'd Plane in a given Time, Computed from the Beginning of it's Motion, will be the half of That, which is deſcrib'd by it, in the ſame Time, with the Velocity laſt Acquir'd; Likewiſe, That the Spaces, deſcrib'd and computed from the Beginning of the Motion, are in a Duplicate Reaſon of the Times or the Velocities, and the Velocities and Times in a Subduplicate Reaſon of the ſaid Spaces.

See Principles of Philoſoph. Chap. 5. Part 1. §. 33.

Corol. 3. HENCE the Aſcent of an Heavy Body up any Inclin'd Plane is a Motion uniformly Retarded, in like Manner, as in the Aſcent of a Body in a Perpendicular, and it is accompany'd with the ſame Properties and Symptoms.

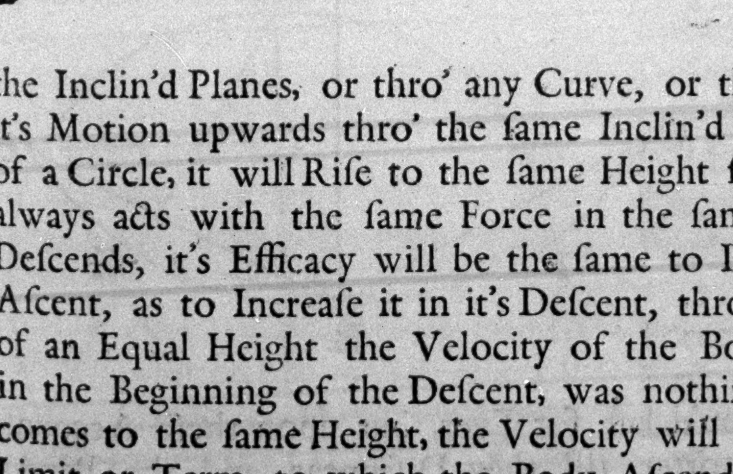
Schol. IF we have Recourſe to Experiments, we ſhall find them Conformable to the foregoing Reaſonings, which it will be Eaſy to Try in Planes, which are not very much Inclin'd; ſince the Motions, being perform'd with a leſs Degree of Velocity, may be Exactly and Critically Meaſur'd, which do's not happen in Perpendicular Deſcents, where the Exceeding Swiftneſs of the Motion leaves no Room for any Accurate Obſervations. It is here to be Noted, that the Planes are ſuppos'd to be perfectly Poliſh'd, and that the Motion is not Obſtructed by any Uneveneſs or Roughneſs of the Surface.

§. 2. AND from hence, Theorem *36th*, It is Demonſtrated, *Fig.* §. 1. That the Time, in which the Inclin'd Plane *AB* is deſcrib'd, is to the Time, in which the Perpendicular *AC* is deſcrib'd, as *AB* the Length of the Plane to *AC* the Length of the Perpendicular;

The other Theorems Recounted, which Relate to the ſame Doctrine.

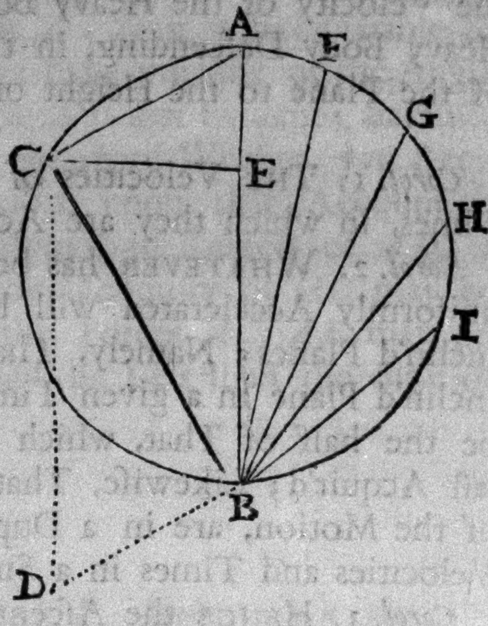
THE *37th*, *Fig.* §. 1. That the Celerities of Heavy Bodies, upon any Inclin'd Plane, and in a Perpendicular, are Equal, when the Heavy Bodies, falling from the ſame Height, come to the ſame Horizontal Line, that is, from *A* to *B* and *C*.

Dr. Keill's Intr. ad Ver. Phyſ. Lect. 15. Theorem 36, 37, 38, 39, 40. Hugen. Horolog. Oſcillator. Prop. 6, 7, 8, 9, &c. Par. 2.

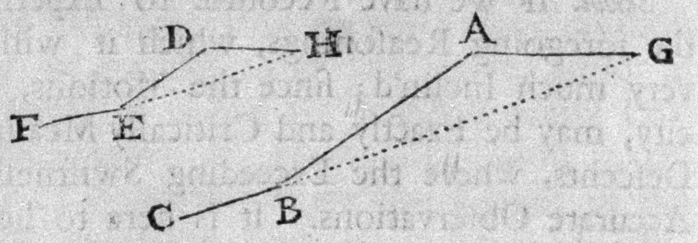


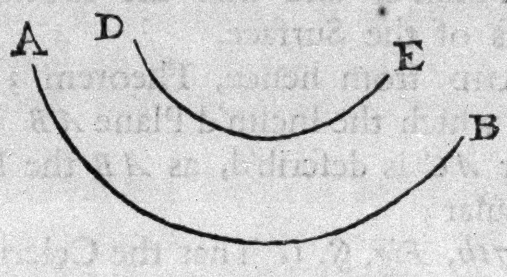
THE *38th*, That if a Body Deſcends in a continu'd Motion from the ſame Height, thro' any Contiguous Inclin'd Planes, *AB*, *BC*, *CD*, or *GC*, *CD*, or *ED*, it will always Acquire the ſame Velocity at the End in *D*, which is Equal to That, which is Acquir'd by it's falling Perpendicularly from a like Height, or from *E* to *F*; From whence it is Infer'd, that, if a Body Deſcends thro' the Circumference of a Circle, or thro' any Curve Lines, which are ſuppos'd to Conſiſt of an Infinite Number of Strait ones, it always Acquires the ſame Velocity, as if it had Deſcended in a Perpendicular from the ſame Height; and if, after it's Deſcent thro' the Inclin'd Planes, or thro' any Curve, or the Circumference of a Circle, it Changes it's Motion upwards thro' the ſame Inclin'd Planes, or Curve, or the Circumference of a Circle, it will Riſe to the ſame Height from which it Fell; becauſe, ſince Gravity always acts with the ſame Force in the ſame Plane, whether the Body Aſcends or Deſcends, it's Efficacy will be the ſame to Diminiſh the Velocity of the Body in it's Aſcent, as to Increaſe it in it's Deſcent, thro' the ſame Line or Space, and in Points of an Equal Height the Velocity of the Body will be the ſame; But the Velocity, in the Beginning of the Deſcent, was nothing, and therefore, in it's Aſcent, when it comes to the ſame Height, the Velocity will be 0, or nought, which Point will be the Limit or Term, to which the Body Aſcends; and conſequently, if a Body Deſcends thro' the Arc of a Circle, or a Curve, to the loweſt Point of that Arc, and afterwards, by the Velocity there Acquir'd, Aſcends thro' an Equal Arc, it will Aſcend and Deſcend thro' Equal Arcs or Spaces in Equal Times;

THE 39*th*, That, if a Circle is plac'd Perpendicular to the Horizon, and from the Higheſt and Loweſt Point of it Two Inclin'd Planes, *AC, BC*, be Drawn to the ſame Point of the Circumference, the Times of the Deſcents thro' either of the ſaid Planes will be Equal to the Time, in which any Heavy Bodies fall Perpendicularly thro' the Diameter *AB*; and therefore all Planes, which are Terminated by the Upper or Lower Point of the Diameter and by the Circumference of a Circle, however Inclin'd, are deſcrib'd in the ſame Time; As *AC, BC, BF, BG, BH*, &c.



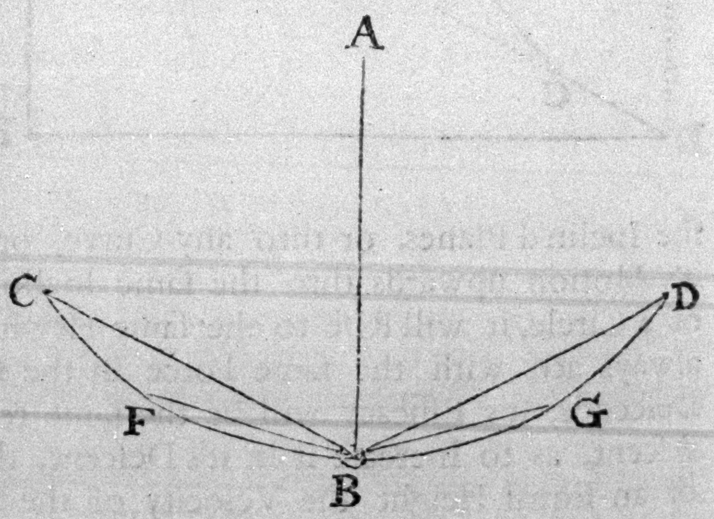
THE 40*th*, That, if Two Heavy Bodies Deſcend upon Two or More Planes, *GABC, HDEF*, that are Similarly Inclin'd and are Proportional, The Times, ſpent in Deſcribing of 'em, are in a Subduplicate Reaſon of the Lengths of the Planes; And the ſame may be ſaid of Two Curve Superficies, *AB, DE*, which are Similar, and have a Similar Poſition, conſider'd as conſiſting of an Infinite Number of Inclin'd Planes, namely, that the Times, ſpent in Deſcribing of them, are as the Roots of the Curves or Lengths.





The Vibrations of the Pendulum from hence explain'd. Dr. Keill's Intr. ad Ver. Phyſ. Defin. Theorem 41.

§. 3. THESE ſeveral Theorems being prov'd by a Geometrick Reaſoning, and Depending upon the Principles above, in the Definition preceding the 41*ſt* Theorem they are apply'd to the Pendulum, or any Heavy Body Swinging by a ſmall Thread upon a fixt Center, which is here given as the Definition of one; If therefore ſuch a Pendulum Oſcillates about ſuch a Center, and deſcribes the Arc of a Circle by that Oſcillation, there will the ſame Motion Arrive to a Body thus Oſcillating, and it will be the ſame Caſe, as if a Body ſhou'd be Mov'd in a Spherical Surface perfectly Hard and Poliſh'd; Becauſe a Motion is ſuppos'd about the Center entirely Free and Abſtracted from the Air's Reſiſtance, which in Heavy Pendulums is very Small and Inconſiderable; If therefore the Pendulum is now drawn to *C* from it's Perpendicular Situation in *AB* and permitted to Swing, it will deſcribe an Arc of a Circle in it's Fall or Deſcent to that Situation, and there Acquire a Velocity, which wou'd Carry it off in a Tangent from *B*, but being Retain'd in a Circle by the Thread, it Riſes in an Arc to the ſame Height in *D*, from which it fell, according to the foregoing Theorems, where, loſing all it's Velocity, it again Deſcends by it's Gravity to it's Perpendicular Situation, and by the Velocity there Acquir'd mounts to it's firſt Height in *C*, and ſo, by Aſcending and Deſcending, it's continual Vibrations are perform'd in the Circumference of a Circle; and if the Motion of Pendulums was not Obſtructed by the Air, and by the Friction in the Center of Rotation, theſe Vibrations wou'd laſt for Ever, but upon theſe Accounts the Arcs deſcrib'd Grow Shorter and Shorter, till they Diſappear, and the Pendulum becomes Quieſcent.



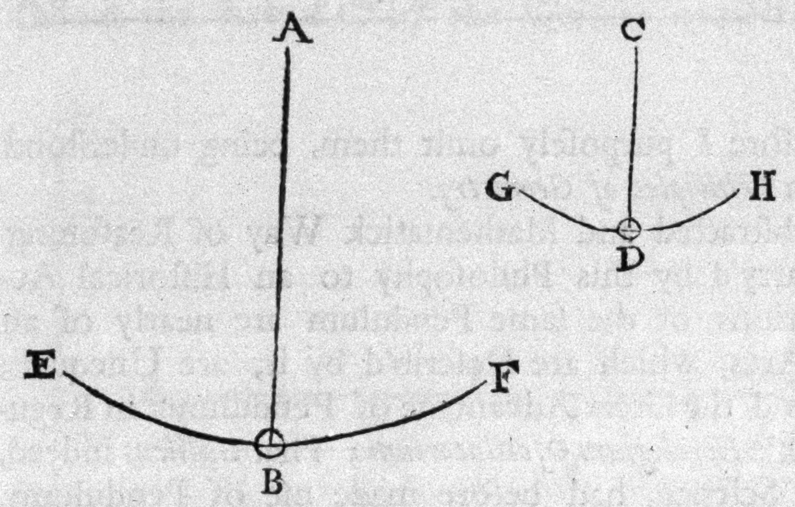
The Vibrations of Pendulums in Unequal

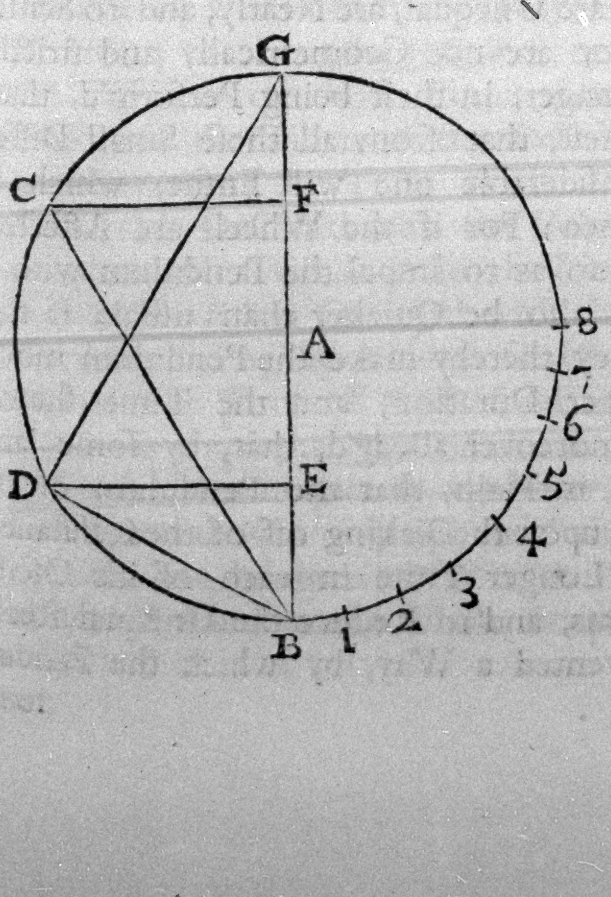
§. 4. AFTER which it is affirm'd, Theorem the 41*ſt*, That the ſmall Vibrations of the ſame Pendulum, however Unequal they are, very Nearly, and to Senſe, are perform'd in the ſame Time, or, which is the ſame, the Oſcillations in Unequal Arcs, if the Arcs are not too Large; becauſe, in ſuch a Caſe, the Arcs and Subtenſes do not much Differ, but, by the foregoing Theorems, the Subtenſes, drawn from any Point of the Circumference to the Bottom of the Diameter, are perform'd in Equal Times; And this Theorem is ſaid to be juſtify'd by Experience, for if Two Pendulums of an Equal Length are ſet a-Swinging, ſo that the one ſhall Deſcribe much Greater Arcs than the other, the Times of the Oſcillations ſhall be almoſt Equal, for in an Hundred Oſcillations there will ſcarcely be the Difference of the Time of One.

Arcs perform'd very nearly in Equal Times. Dr. Keill's Intr. ad Ver. Phyſ. Theorem 41.

§. 5. The 42*d* Tells us, That the Times or Durations of the Oſcillations of Two Pendulums, which deſcribe Similar Arcs, *EF, GH*, are in a Subduplicate Reaſon of the Lengths of the Pendulums *AB, CD*; Becauſe, by the foregoing Theorems, ſince the Arcs are Similar, the Time of the Deſcent thro' *EB* will be to the Time of Deſcent thro' *GD*, in a Subduplicate Reaſon of *EB* to *GD*; that is, half the Times of the Oſcillations will be in a Subduplicate Reaſon of half the Arcs, and therefore the Times of the whole Oſcillations will be in a Subduplicate Reaſon of Them; but the Arcs or half Arcs being Similar are as the Semidiameters, which deſcribe them, or as the Lengths of the Pendulums, and conſequently the Durations or Times of the whole Oſcillations will be in a Subduplicate Reaſon of thoſe Semidiameters or Lengths; From whence it follows, that, on the Contrary, the Lengths of the Pendulums are in a Duplicate Reaſon of the Times or Durations, in which the Oſcillations are Perform'd; And ſince the Durations or Times of the Vibrations are Reciprocally, as the Number of Vibrations perform'd in the ſame Time, it will be Eaſy, from the Number of Vibrations Given, which are made by one Pendulum *P* of a known Length in a Time Given, to Determine the Number of Vibrations, which are made in the ſame Time by another Pendulum *p* of a known Length; for as *P, p* Repreſent the Lengths of the Pendulums, Let *N, n* Expreſs the Numbers of the Vibrations of the ſaid Pendulums, and *T, t* the Times; *N* therefore is here Given, and *n* is the Number to be found; By the Preſent Theorem $T . t :: \sqrt{P} . \sqrt{p}$, and by what has been now alledg'd, $T . t :: n . N$, conſequently, $n . N :: \sqrt{P} . \sqrt{p}$, or $\sqrt{p} . \sqrt{P} :: N . n$, but $\sqrt{P}$, $\sqrt{p}$, and N, being known, *n* likewiſe will be Aſcertain'd; On the Contrary, from the Number of Vibrations Given, *N, n*, which are perform'd by the Two Pendulums in the ſame Time, and from the Given Length of one of Them *P, p* the Length of the other may be Defin'd, for $P . p :: T^2 . t^2 :: n^2 . N^2$, by what forego's, therefore $n^2 . N^2 :: P . p$.

The Times or Durations of the Vibrations of Pendulums in a Subduplicate Reaſon of the Lengths of the Pendulums. Dr. Keill's Introduct. Theorem 42.



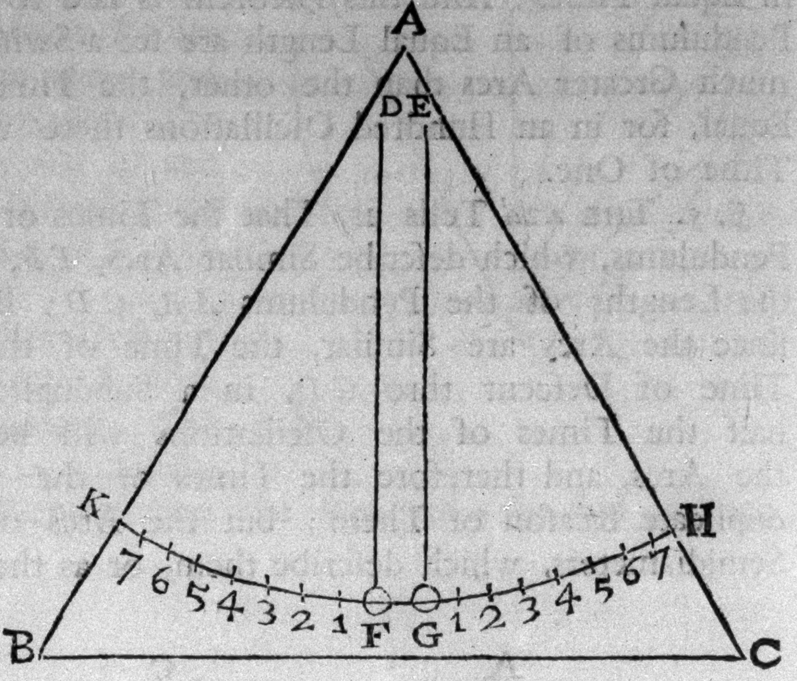


§. 6. The 43*d* Informs us, That the Velocity of a Pendulum, in it's Loweſt Point *B*, is as the Subtenſe of the Arc, which it Deſcribes in it's Deſcent; which Depends upon the Truth of the preceding Theorems; if therefore, from the ſaid Loweſt Point, ſuch Arcs be taken upon the Circumference of a Circle, deſcrib'd by the Pendulum, that their Subtenſes ſhall be, as 1, 2, 3, *&c.* Reſpectively, and ſome Acting Force Impels the Pendulum upwards, thro' the Firſt, Second, or Third Arc, *&c.* the Velocities of the Pendulum, mov'd by theſe Forces, will, in the Loweſt Point, be as 1, 2, 3, *&c.* Reſpectively; by which means, we may Impart Different Velocities to a Pendulous Body in any Reaſon aſſign'd, and thoſe, which are deriv'd

The Velocity of a Pendulum in it's Loweſt Point, as the Subtenſe of the Arc, which it Deſcribes in it's Deſcent. Dr. Keill's Introduct. Theorem 43.

riv'd from the Percuſſion of another Body, may be compar'd with one another, as well as with others, which are Originally Given.

Thus, if Two Pendulums of the ſame Length, *DF*, *EG*, hang Cloſe together, ſo that the Pendulous Bodies touch, and the one is drawn from it's Perpendicular to the Point 5 in one Arc, and the other to the Point 3 in the Oppoſite, and are then let Looſe; by the Theorems above, they will come to the Perpendicular at the ſame Time, and the Velocities with which they ſtrike each other will be as 5 and 3; and if, after Percuſſion, the Firſt Riſes to 3, and the Laſt to 5, their Velocities will be Exchang'd, and will be as 3 and 5 to Contrary Sides; And by a like Method, the Rules of Motion, both in Hard and Elaſtick Bodies, before Explain'd, may be Reduc'd and Submitted to Experience; The Demonſtrations of theſe ſeveral Theorems are Celebrated and Known, and therefore I purpoſely omit them, being underſtood by any one, who knows the Common *Principles of Geometry.*



The Hiſtory of Pendulums, and the Advances made in that Science, and by Whom.

§. 7. Thus far we are got in the Abſtracted and Mathematick Way of Reaſoning upon Pendulums, and now we are carry'd by this Philoſophy to an Hiſtorical Account of Them; That the leaſt Vibrations of the ſame Pendulum are nearly of an Equal Time or Duration, altho' the Arcs, which are Deſcrib'd by it, are Unequal; That *Chriſtian Hugens*, from hence, ſhew'd the Great Advantage of Pendulums in Regulating the Motions of Automatons, in his *Horologium Oſcillatorium*; That *Galileus* indeed, the firſt Author and Inventor of this Science, had before made uſe of Pendulums, in his Obſervations in Aſtronomy and Nature, which require an Exact Meaſure of Time; That *Hugens*, notwithſtanding, was the Firſt, who Introduc'd Automatons with Pendulums, and Prov'd them, by Experiments, far to Exceed thoſe, which before Obtain'd, whoſe Librators were Horizontal; That from thence Theſe Automatons were generally Receiv'd, ſome of which have been ſo Artificially made, as to give a Meaſure of Time, much Juſter and more Exact than the Motion of the Sun, which ſhews the Apparent or Relative Time only, but not the Real and Abſolute; From whence it comes to Paſs, that Pendulums, at Certain Times, ſhew the Hour Different from the Apparent one, and ſometimes Fifteen or Sixteen Minutes more or above what is Pointed out by the Sun-Dial, and at others, ſo many Leſs, and it is not, Excepting Four Times in a Year, that the Pendulum and the Sun Agree;

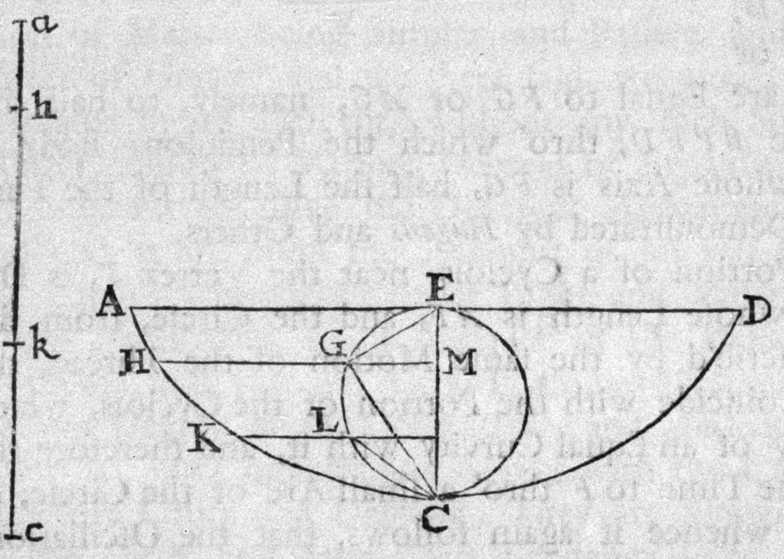
Dr. Keill's Aſtronom. Lect. 26. Pag. 413. Edit. 1.

It is farther ſaid in this Hiſtory of Pendulums, that, altho' the Vibrations of the ſame Pendulum, where the Arcs deſcrib'd by it are Unequal, are Nearly, and to Senſe, of an Equal Time and Duration, yet, ſince they are not Geometrically and ſtrictly ſo, but the Greater Vibrations are ſomething Longer, in their being Perform'd, than the Leſs, and by that means Differ, it is manifeſt, that from all theſe Small Differences taken together, at Length a very Conſiderable one will Enſue, which is Matter of Fact, and what we find by Experience; For if the Wheels are Affected with a Kind of Stiffneſs, as in Cold Weather, ſo as to Impel the Pendulum with a Leſs Force, the Oſcillations being Shorter will alſo be Quicker than uſual; If the Wheels have too Great a Lubricouſneſs, and they thereby make the Pendulum move in Larger Arcs, the Oſcillations are of a Longer Duration, and the Time ſhewn by the Pendulum proceeds Slower; It is alſo moreover alledg'd, that, by ſome late Experiments in the *Philoſophical Tranſactions*, it is Plain, that the Pendulum of an Automaton, Performing it's Vibrations in Vacuo, upon the Taking off of the Reſiſtance of the Air, deſcrib'd Greater Arcs, and was a Longer Time in each of it's Oſcillations; To Remedy this Inaccuracy of Pendulums, and to Reduce the Unequal Reciprocations of them to Equal Times, *Hugens* Invented a Way, by which the Pendulous Body ſhou'd be carry'd in the Arc of a Cyclois, but, by the Nature and Properties of that Figure, the Times of the Deſcents of Heavy Bodies, thro' any Arcs to the Loweſt Point or Vertex of it, are Equal, and therefore, if the Pendulous Body always Moves in the Arc of a Cyclois, the Times of it's Oſcillations will be exactly Equal, whether the Pendulum Vibrates in Greater or Leſs Arcs.

§. 8. In order therefore to Demonſtrate this Property of the Cyclois, Theorem the 45*th.* it is propos'd to be Prov'd, That, if a Body is urg'd in a Right Line towards a Center, by Forces which are Proportional to the Diſtances from the ſaid Center, Let it fall from any Height, It will always come to the Center in the ſame Time; and that Time is to the Time, in which the Body can Deſcribe the ſame Path with a uniform Velocity and Equal to That, which is Acquir'd at the End of it's Fall, as the Semiperiphery of a Circle to it's Diameter.

The Cyclois Introduc'd by Hugens, *in which all the Vibrations of a Pendulum are Equal, tho' the Arcs are Unequal.*

The 46*th* Shews, That, in a Cyclois, whoſe Axis ſtands Perpendicular to the Horizon, and whoſe Vertex is Inverted, the Times, in which a Body, urg'd by the Force of Gravity and let fall from any Point in the ſaid Cyclois, arrives at the Vertex, are Equal, and, to the Time of it's Perpendicular Deſcent thro' the Axis, are in the Proportion of the Semiperiphery of a Circle to it's Diameter. Thus let ACD be a Cyclois, whoſe Axis is CE and it's Generating Circle ECG; ſince the Tangent in any Point H is Parallel to the Chord CG drawn in the Generating Circle Form'd about the Axis EC, by the Writers upon this Figure it is manifeſt, that the Body in it's Deſcent is Accelerated with the ſame Force in H, as if it had Deſcended thro' the Right Line GC; But the Force, with which it is Accelerated in GC, is to the Force of Gravity, as MC to GC, by what foregoes, and $MC.GC::GC.CE$, by Elem. 6. Prop. 8. Therefore the Force, with which the Body is Accelerated in H, is to the Force of Gravity, as GC to CE; by the ſame Reaſoning, the Force of Gravity is to the Force, with which the Body is Accelerated in any other Point K, as CE to CL, and conſequently, *ex Æquo*, the Force, with which the Body is Accelerated in H, is to the Force, with which it is Accelerated in K, as GC to LC, or as the Double of GC to the Double of LC, that is, by the Writers upon this Figure, as the Curve of the Cyclois HC to the Curve KC; The Forces therefore, with which a Body is Accelerated in it's Deſcent upon a Cyclois, are as the Lengths of the Curve to be Deſcrib'd; Let us now ſuppoſe the Right Line ac Equal to the Length of the Curve AC, and let a Body be Conceiv'd to be urg'd with the ſame Forces in the Right Line ac towards c, with which the Body is urg'd in it's Deſcent thro' the Curve AC; But the Forces, with which the Body is urg'd in any of the Points of the Cyclois H and K, are as the Lengths HC, KC, or hc, kc, that is, the Forces in any Places, are as the Diſtances of thoſe Places from the Point c, and therefore, by the Preceding Theorem, the Times of the Deſcents from any Height are Equal.



Dr. Keill's Intr. ad Ver. Phyſ. Lect. 15. Theorem 45, 46.

Hugen. Horolog. Oſcillator. Prop. 25. Par. 2.

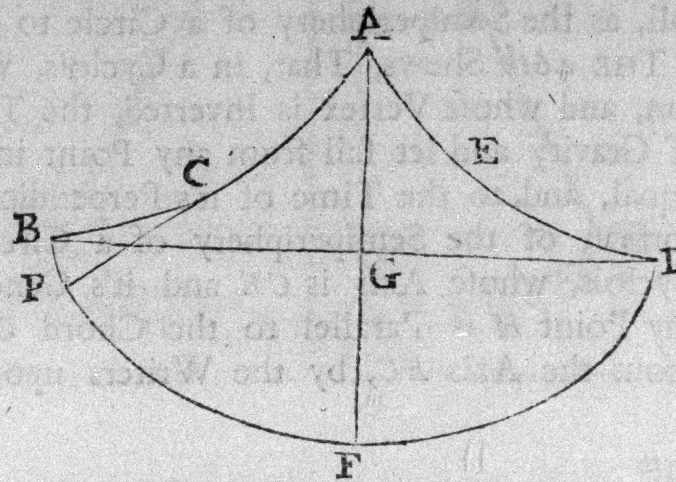
Moreover, the Time of the Deſcent from a to c is to the Time, in which ac or $2EC$ is Deſcrib'd with the Velocity Acquir'd at the End of the Fall, as the Semiperiphery of a Circle is to the Diameter, by the Preceding Theorem; but the Time, in which $2EC$ is Deſcrib'd with the ſame Velocity, is Equal to the Time, in which the Body falling by it's own Gravity Deſcends thro' EC the Axis of the Cyclois; from whence the Time of the Deſcent thro' ac, or AC is to the Time, in which the Body Deſcends thro' the Axis of the Cyclois, as the Semiperiphery of the Circle to the Diameter; Conſequently, the Time, in which the Body Deſcends in the Cyclois thro' the Arc AC, and Aſcends thro' that of CD, that is, the Time of the Motion thro' the whole Cyclois ACD is to the Time of the Perpendicular Deſcent thro' the Axis of the Cyclois, as the whole Periphery of the Circle to it's Diameter.

§. 9. If

How to make a Pendulum Vibrate in a Cyclois. Dr. Keill's Intr. ad Ver. Phyſ. Theorem 46. Hugen. Horolog. Oſcillator. Definit. & Prop. 6. Par. 3.

§. 9. If therefore a Pendulous Body Vibrates in a Cyclois, whether it Performs Greater or Leſſer Arcs, the Oſcillations will be always made in Equal Times; but how to Effect, that a Pendulous Body ſhou'd Vibrate in a Cyclois, is the Difficulty, which *Hugens* has ſhewn the Way to Surmount, in his *Horologium Oſcillatorium*, Part the Third.

Thus, a Curve is to be found, by whoſe Evolution the Curve Given is Deſcrib'd, and Two Plates are to be Bent into the ſame Curvature, betwixt which the Pendulous Body, Hanging by Threads of a Certain and Determin'd Length, do's not Deſcribe a Circle, but ſome other Curve; Let Two Plates, *ACB*, *AED*, be Bent into Similar and Equal Figures, and from the Point *A* let the Thread of the Pendulum be ſuſpended, which, whilſt the Pendulum Oſcillates, Wraps it ſelf Round the Plates, *ACB*, *AED*, to which it always Adheres and Adapts it ſelf; by this Application of the Thread to the Plates, the Motion of the Pendulum in a Circle is continually Interrupted and Hinder'd, and the Pendulous Body is carry'd thro' the Curve *BPFD*; the Curve *ACB* or *AED* is call'd the Evolute, and the Curve *BPFD* is ſaid to be Deſcrib'd by Evolution; If the Curves, *ACB*, *AED*, are two Semicyclois's, whoſe Axes or Diameters of the Generating Circles are Equal to *FG* or *AG*, namely, to half the Length of the Pendulum, the Curve *BPFD*, thro' which the Pendulous Body is carry'd, becomes an entire Cyclois, whoſe Axis is *FG*, half the Length of the Pendulum, according to what has been Demonſtrated by *Hugens* and Others.



The ſmalleſt Arcs of the Cyclois and the Circle nearly Coincide.

§. 10. Furthermore, Since the Portion of a Cyclois, near the Vertex *F*, is Deſcrib'd by the Motion of a Thread, whoſe Length is *AF*, and the Circle, from the Center *A* at the Interval *AF*, is Deſcrib'd by the ſame Motion of the Thread, the Circle, Paſſing thro' *F*, will nearly Coincide with the Portion of the Cyclois, which is next to the Vertex *F*, and is nearly of an Equal Curvity with it, and therefore the Pendulous Body is carry'd in the ſame Time to *F* thro' a ſmall Arc of the Circle, as thro' an Arc of the Cyclois; From whence it again follows, that the Oſcillations of a Pendulum, thro' the ſmall Arcs of a Circle, will be perform'd in Equal Times, ſince thoſe in a Cyclois, with which they nearly Coincide, are ſo.

The Time therefore, in which a Pendulum performs the leaſt Oſcillation in a Circle, is Equal to the Time, in which an Oſcillation is perform'd thro' the Arc of a Cyclois, whoſe Axis is half the Length of the Pendulum; But the Time, in which the Oſcillation in a Cyclois is perform'd, is to the Time of the Perpendicular Deſcent thro' the Axis of the Cyclois, that is, thro' half the Length of the Pendulum, as the Periphery of the Circle to the Diameter; and from hence it is Conſequent, that the Time of Every the leaſt Oſcillation is, to the Time of the Deſcent thro' the Length of the Pendulum, in a Conſtant and Certain Proportion of the Periphery of the Circle to the Diameter of it, Multiply'd into the Square-Root of Two.

The Vibrations of a Pendulum Slower, when Nearer to the Æquator, than when Farther from it.

§. 11. If, in Different Climates and Regions of the Earth, the ſame Pendulum performs it's Oſcillations in Unequal Times, the Times of the Deſcents thro' the Length of the Pendulum in theſe Different Climates will be likewiſe Unequal, and where the Oſcillations Proceed Slower, the Body will Deſcend Slower in a Perpendicular, and in a Given Time will Deſcribe a leſs Space in it's Fall; but it is Certain by Experiment, that in thoſe Regions, which are Neareſt to the Æquator, the Oſcillations of the ſame Pendulum are Slower than in other Places, whoſe Latitude is Greater, and therefore Heavy Bodies, in thoſe Countries, Deſcribe in their Fall a leſs Space in a Given Time, and are leſs Accelerated in their Motion than in Ours, which is farther Remov'd from the Æquator; ſo that by Experiments it is Evinc'd, that the Action of Gravity is Leſs in thoſe Places, whoſe Latitudes are Leſs, than in Places, which are Nearer to the Pole;

Which Decreaſe of Gravity is ſaid to ariſe from the Centrifugal Force, deriv'd from the Earth's Rotation about it's Axis, which is Greater, as the Circuits of the Bodies Revolving are ſo, and is always therefore as the Sine of the Diſtance of the Place from the Pole, which under the Æquator is Greateſt, and under the Pole none; and conſequently, the Force of Gravity, in the Æquator, is the Leaſt, and, in the Pole, the Greateſt. This is a full and ſuccinct Account of the Doctrine of Pendulums, and of the Deſcent of Heavy Bodies in Inclin'd Planes, into both of which we ſhall now Inquire.

The Reaſon of the Deſcent of Heavy Bodies, and their Acceleration to the Earth.

§. 12. As to the Deſcent of Heavy Bodies in Inclin'd Planes, §. 1, we muſt obſerve, that, in Order to juſtify this Reaſoning, the Force of Gravity being Reciprocally Proportional to the Squares of the Diſtances, a Favorite Notion of the Preſent Philoſophy, is Diſcarded, which is it's Firſt Abſtraction, and tho', upon the Account there mention'd, where the Difference of the Diſtances is very Small, the Difference of the Force of Gravity may not be Conſiderable, yet it is ſomething, and takes from the Geometrick Exactneſs of theſe Demonſtrations, but this we Paſs over; And the next and moſt Material Objection againſt this Doctrine is, that it ſuppoſes Matter to be Similar and Homogeneous, to have no Intrinſick Forces of it's own, neither Expanſive nor Contractive, to be entirely Paſſive in it ſelf, and only Acted with one uniform Force of Gravity, and that this Force of Gravity urges it by Continual and Succeſſive Impulſes, by which it is Equably Accelerated; On the Contrary, we have, in our firſt Part of the *Principles of Philoſophy*, endeavour'd to confute this Opinion of Matter being Similar and Paſſive, and being Acted upon by uniform Impulſes of Gravity, and we there ſaid, we wou'd give a Solution of Matter's being Accelerated in it's Deſcent, without any ſuch Suppoſitions; We therefore affirm, that Matter conſiſts of Various Degrees of Expanſive and Contractive Forces, which will be ſufficient to ſolve the Different Appearances we find in it; that Fire do's not Deſcend at all, upon the Account of it's vaſt Expanſive Force, which is oppoſite to the Earth's Contractive; that Light and Volatile Bodies Deſcend leſs than others, which are Heavier, upon Account of the ſame Expanſive Force being more ſenſible in them; and that the Groſſeſt Bodies Deſcend the moſt, as being endu'd with a Greater Degree of the Contractive, and conſequently with a Force, which is not Oppoſite to, but Concurrs and Agrees with the Contractive of the Earth, to which they therefore Unite and Deſcend; They are likewiſe Accelerated, the Nearer they come to the Earth, and have a leſs Tendency to it, the Farther they are from it, for the ſame Reaſon, that the Expanſive Force of Fire obtains a Greater Effect upon Inflammable or Expanſive Matter, when Near, than when at a Diſtance, and for the ſame Reaſon, that all other Forces are ſtronger, in their Actions upon each other, when leſs Retir'd, than when more ſo; And from hence it is manifeſt, that Various Bodies are more or leſs Accelerated to the Earth, according to the Different Degrees, which they have, of the Contractive or Expanſive, and that the ſame Bodies are Accelerated towards it, if of a Contractive Nature, rather in a Reciprocal, than in a Reciprocally Duplicate, Proportion to their Diſtances; for thoſe of an Expanſive Retire actually from it, as Fire, or Endeavour, in ſome Meaſure, to do it, as Light and Volatile Bodies.

Principles of Philoſ. Chap. 5. Part 1. §. 18.

See Chap. 5. of this Book.

See Schol. §. 1.

As to what is here ſaid of Experiments, It is Confeſs'd, that the Perpendicular Deſcents of Bodies cannot be Determin'd by Them, and Thoſe in Inclin'd Planes are own'd not to Agree Exactly with the Doctrine Aſſerted from Abſtraction and Reaſon, which therefore may be as well Aſcrib'd to ſomething in the Expanſive and Contractive Forces, as to the Uneveneſs of the Surface, on which the Experiments are made. Farther, it is not Evident, that Bodies are more Accelerated, Preciſely, as They come Nearer to the Earth, and Leſs, as they Retire from it, ſince Forces do not always Exert themſelves more or leſs, as we Approach to them, or Recede from them; many Times they Exert themſelves to a Great Degree in a near Approximation to 'em, and not at all at ſome farther Diſtance from them, as in Fire, which is of an Expanſive Nature, and in Snow, which is of a Contractive one; and thus it may be, in Reſpect of the Earth, that tho' Heavy Bodies, near it, are vehemently Urg'd and Accelerated towards it, yet, at a Greater Diſtance from it, they may not be Gradually Diminiſh'd in ſuch their Acceleration;

celeration; but this we have Diſcours'd of in another Place, where we conſider'd the Propagation of Action from a Center.

Why the ſeveral Theorems Recounted, §. 2. *are not True, and that Bodies do not Riſe to the ſame Height from which they Fell.*

§. 13. THE ſeveral Theorems, in §. 2, Depending upon theſe Principles of a Similar and Paſſive Matter, without any Intrinſick Forces belonging to it, and upon uniform Impulſes from Gravity, which are all of them Chimerical Fancies and Mere Suppoſitions, all the Demonſtrations, which belong to them, will be only a Mathematick and Abſtracted Reaſoning upon Properties and Things, which have no where an Exiſtence, but in the Mind, which Creates them; Beſides which, in the 38*th* Theorem, mention'd in the ſame Section the 2*d*, It cannot be Conceiv'd, how a Body ſhou'd Aſcend, thro' ſeveral Inclin'd Planes or thro' a Curve, to the ſame Height, from which it fell, by the ſame Action and Impulſe of Gravity, and then Deſcend, and ſo alternately in continual Vibrations; becauſe, tho', ſuppoſing the Body to be Accelerated and to Acquire a conſiderable Velocity by a large Deſcent, that Velocity wou'd be Gradually Diminiſh'd in the Bodies Aſcent in a Spherical Surface, till it was Deſtroy'd, when it came to the ſame Height from which it fell, and then it wou'd again Deſcend and be Accelerated, the Contrary Way, by the Perpetual Action and Impulſe of Gravity, if Matter was at the ſame Time Paſſive, and had no Internal Force of it's own, yet this is not Fact; ſince a Globe of Lead will not riſe to near the Height from which it fell, nor is it Reaſonable it ſhou'd, if it has in it ſelf a Force, Reluctant to a Velocity Impreſs'd, which it has, by being of a Contractive Nature, whereas other Bodies, which are of a more Expanſive and Elaſtick, will riſe to a Greater Height by their concurring with the Force of Velocity Acquir'd, which is likewiſe of an Expanſive one: Moreover, where the Deſcent of Heavy Bodies is Small and Inconſiderable, which is the Caſe of Pendulums, we cannot Imagine, that there is any ſenſible Acceleration, ſo as by a Velocity Acquir'd it ſhou'd Aſcend at all, or at moſt, to a very little Height; We think, that they are rather carry'd down by their Gravity with a moſt Minute Velocity imparted to them, and therefore, that they are ſtop't and hinder'd from Riſing far by the ſame Force, by which they Deſcend. This therefore appears to be the Real Theory of Deſcending Bodies in a Spherical Surface, and that the Expanſive and Contractive Forces, which Reſide in them, Enter into the Account, and are the Reaſon of their Riſing to a Greater or Leſs Height, after their Deſcent, which will but Illy Agree with their Riſing to the ſame Height, from which they fell, by the Paſſiveneſs of Matter and the uniform Impulſes and Action of Gravity; and hence will be ſeen the Vanity of that Proportion, that the Times, ſpent in Deſcribing Similar Curves or Planes Similarly Inclin'd, are in a Subduplicate Reaſon of the Curves or Lengths.

The Doctrine of Pendulums Conſider'd, and the True Theory of them Explain'd.

§. 14. FROM the Deſcent of Bodies, in Curves or Inclin'd Planes, we are Led to the Vibrations of a Pendulum, for which the preceding Doctrine was Principally Contriv'd; and the firſt Step, which is made, is to let us know, §. 3, that the Caſe of Deſcending Bodies, in Curves or Inclin'd Planes, is the ſame with that of the Oſcillations in a Pendulum; that the Center of Suſpenſion, from which the Pendulum Oſcillates, performs the ſame Office, in Retaining the Body in it's Circular Vibrations in the one Circumſtance, as the Spherical Surface do's in the other; that they are alike Accelerated by Gravity and Deſcend by it, and Aſcend by the Velocity Acquir'd, till that Velocity is Loſt by the Action of Gravity, when they again Deſcend, *&c.* But here is the Diſtinction, that, in Bodies Deſcending in Inclin'd Planes, the Gravity of them, and the Velocity ariſing from thence, and the Determination of their Motion from the Inclination of the Planes, are only to be Conſider'd; whereas, in the Pendulum, the Two Former do not only Enter into the Account, and the Latter from the Detention of them in a Circle, but alſo the Center of Suſpenſion has an Effect peculiar to it, and to which there is nothing Analogous in the mere Deſcent of Bodies thro' Inclin'd Planes, and conſequently, the Demonſtrations of the one cannot be Reaſonably Extended to the Properties of the other; for it is not the ſame Thing for a Body to be carry'd Round in a Sling, where there is a Perpetual Centrifugal Force Exerted, and for a Body to Roll upon a Table, whether Plane or Concave, without any Center, from which it Endeavours to Recede.

The Nature of Pendulums, and the Reaſon of their Oſcillation.

The Nature of Pendulums and of their Vibrations therefore ſeems to be this, which will ſufficiently Diſtinguiſh them from the Deſcent of Bodies only upon Inclin'd Planes, that, when any Heavy Body hangs, by a String, from the Center of Suſpenſion, there are Two Contrary Forces, which act againſt each other, the one in the ſaid Center, which is a Force of Contraction, by which it Endeavours to bring the Pendulous Body towards it, the other an Expanſive Force in Reſpect of that Center, by which it Endeavours to Recede from it, by it's Gravitation to the Earth, Theſe, Acting againſt each other and the Contractive prevailing, a Quieſcence enſues; but, if to the Expanſive Force of the Pendulous Body is added the Expanſive of Percuſſion by the Hand or by any other Inſtrument, or of a Greater Weight and Gravity, ſo as to Exceed the Contractive of the Center, the Thread is Broken and the Body Deſcends to the Earth; If by this Percuſſion the Expanſive do's not Exceed the Contractive, there is a Conteſt betwixt the one and the other, by which the Oſcillations are Produc'd; for the Pendulous Body cannot Recede from the Center, and it is leſs from Approaching towards it, than before this New Addition of the Expanſive; and conſequently, the Force muſt be ſpent in Circulating Backwards and Forwards, till at length by the Prevalence of the Contractive in the Center, it becomes again Quieſcent.

Why Heavier Pendulums will Oſcillate longer than Lighter ones.

And First, From hence it is manifeſt, that Heavier Pendulums will Oſcillate longer than Lighter ones, becauſe the Expanſive Force in Heavier Bodies, in Reſpect to the Center of Detention, is Greater than that of Lighter ones, and if there is an Addition of the Expanſive Force by Percuſſion, it will be longer before the Contractive Force of the Center prevails in the one Caſe, than the other; which is Contrary to the Deſcent of Bodies in Inclin'd Planes, where Lighter and more Elaſtick ones will Aſcend and Deſcend to a longer Time than Lead will, which is ſoon Quieſcent.

On the other Hand, this Phænomenon is Explain'd by the Difference of the Air's Reſiſtance, which is leſs in Proportion to Heavier Bodies than to Lighter, but if that is a true Solution, it ſhou'd be told us, why the Reſiſtance of the Air has not the ſame Effect in the Deſcent of Heavier Bodies thro' Inclin'd Planes, which it Apparently has not, and therefore the Solution I have given ſeems to be the moſt Rational.

Why the leaſt Vibrations of the ſame Pendulum are nearly of an Equal Time.

Second, From hence likewiſe is Evident, the Reaſon, why the leaſt Vibrations of the ſame Pendulum are nearly of an Equal Time or Duration, but yet that it will Deſcribe longer Arcs, in ſomething a longer Time, than ſhorter ones; becauſe the Expanſive Force of the Pendulum, which Acts againſt the Contractive of the Center of Detention, is chiefly owing to the Gravitation of the Pendulous Body, by which it Endeavours to Recede from that Center, but that Force being always the ſame and conſtant, and the Gentle Percuſſion, by which it is put into Motion, adding Little to it or Equably doing it, and the Arcs being ſmall, it is Plain, that ſuch Unequal Arcs will be nearly Perform'd in the ſame Time, tho' not Exactly ſo, becauſe Really the ſame Force will Deſcribe a longer Arc in a longer Time, and a ſhorter one in a Shorter; for this Phænomenon the preſent Philoſophy gives no Solution, but takes it for Matter of Fact, that the Vibrations are Perform'd Exactly and Geometrically in the ſame Time, Raiſes Theorems and Proportions upon it, and then Confeſſes, that they are not perform'd Geometrically in the ſame Time, but that longer Arcs Require a longer Time to Deſcribe them, and the Shorter, a Leſs.

Why Pendulums Oſcillate Slower, when nearer to the Æquator, and Quicker, when nearer to the Poles.

Third, From hence laſtly is Explain'd, why Pendulums Oſcillate Slower, when nearer to the Æquator, and Quicker, when nearer to the Poles, becauſe the Expanſive Force of the Sun's Heat Acts contrary to and Enervates the Contractive Force of the Pendulum, by which it Acts leſs againſt the Contractive Force in the Center of Detention, as Bodies, turn'd into Fire and Flame, Gravitate leſs, and put on the Force of the Expanſive; On the other Hand, the Contractive Force of Froſt and Cold, near the Poles, concurrs with and ſtrengthens the Contractive Force of the Pendulum, by which it is Envigorated in it's Action againſt the Contractive Force in the Center of Detention, and thereby the Vibrations are Quicken'd; and for the ſame Reaſon, Pendulums Oſcillate Faſter in Winter than in Summer, and in Colder Seaſons than in Hotter; whereas the Reaſons alledg'd for the Solution of theſe Phænomenons, by the Philoſophy before us, are Various and do not Confirm, but Contradict each other;

for the firſt is ſaid to Proceed from the Earth's Rotation, by which Gravity is Diminiſh'd more in the Æquator than in the Poles, which can be of no Service to Account for Pendulums, whoſe Oſcillations Differ in the ſame Climate, purely upon Account of the Difference of Heat and Cold; and the laſt is ſaid to Proceed from a Difference of the Air's Temperature, which cannot Explain thoſe Phænomenons, which are affirm'd to ariſe from a Different Situation to the Pole and the Æquator.

However, notwithſtanding theſe Miſtakes in the Nature of the Pendulum, and this Philoſophy's being oblig'd to own, that the Oſcillations of it are, in Unequal Times, in Unequal Arcs, tho' it had hitherto Reaſon'd upon the Suppoſition, that they were perform'd, in Equal Times, in Unequal Arcs, it can Paſs all this Over, and thinks to Correct all Irregularities by the Help of the Cyclois, albeit, by ſo many Arguments, as the Cyclois is Introduc'd, by ſo many is the former Doctrine Diſcarded, and yet, which is ſtrange, it Retains and Makes uſe of it; Let us therefore now Conſider, what farther is advanc'd in Relation to that Figure;

And Firſt, in order to Demonſtrate the Property of the Cyclois, which is Wanting, the ſeveral Abſtractions of a Similar, Paſſive, and Gravitating Matter are Preſum'd, which have been before Diſputed; alſo that Gravity Acts by Conſtant and Uniform Impulſes, which is either Falſe, or remains a Queſtion; and that the Motion of Pendulums is the ſame as, and may be Explain'd by, the mere Gravity and Deſcent of Bodies in Inclin'd Planes, which is not Granted; Theſe Points, being not Explicite and Clear, hinder us from allowing *Hugens* to be the moſt Accurate Philoſopher, how much Sagacity and Penetration ſoever we may be willing to Give to his Geometry.

In the ſecond Place, if all theſe Abſtractions and Preſumptions were acknowledg'd and ſubmitted to, the Way, which is preſcrib'd for the Oſcillation of a Pendulum betwixt Two Cyclois's, in order to make the Pendulous Body Deſcribe a Third, is Impracticable and Romantick; for whatever Schemes we may Form to our ſelves, or whatever Mathematick Reaſonings we may Advance, it will be ſtill Certain, that the Oſcillations are Perform'd very nearly in the Arcs of a Circle, ſince, tho' the String of the Pendulum ſhou'd Wrap it ſelf about the Cyclois's, betwixt which it Vibrates, the very Inſtant it departs from them, the Body will be found in the Arc of a Circle, from it's ſtretching the String, by it's Gravitation, to a Radius of it, unleſs we can Imagine a Heavy Body to Oſcillate at the End of a String not ſtretch'd, but bent into a Curve; which muſt be the Reaſon, that Artificers, not perceiving the Advantage, from Experiment, of theſe Cyclois's, uſe no ſuch String, but a Stiff and Inflexible Iron-Rod, at the End of which the Body is affix'd, and which therefore can Oſcillate in no other Figure, than that of a Circle; and from hence it is, that Dr. *Keill* Labours to ſhew, (for no Curves of a Different Nature will), that the ſmall Portions of a Circle and Cyclois Coincide, which is as much as to Confeſs, that, after all theſe Fine Demonſtrations concerning the Properties of the Cyclois's in the *Horologium Oſcillatorium*, the Pendulum will do as well without them, by Oſcillating only in the Plain Arcs of a Circle; It is true, there is ſomething ſubſtituted in the Room of the Cyclois, that is, a Flat, Thin, Iron-Plate, Tranſverſe to the Plane of Oſcillation, by the bending of which, in the Vibrating, the Pendulum is Shorten'd, and by which the ſame Effects are ſuppos'd to be Produc'd, as if the Pendulum had Oſcillated betwixt Two Cyclois's; However this may be found in Practice, no Mathematician can ever Prove, that the ſhortening of the Pendulum, by drawing the Flat Plate up into the Arc of a Circle, is the ſame, in a Geometrick Figure, as the ſhortening of the Pendulum, by ſtriking againſt a Cyclois; and if not, either this Doctrine of the Cyclois is unneceſſary to the Explanation of the Pendulum, or elſe another ought to be Contriv'd, by which it may be Geometrically Evinc'd, that the Shortening of a Pendulum, by the Contraction of the Plate into the Arc of a Circle, is the ſame as a Pendulum, Oſcillating betwixt Two Cyclois's.

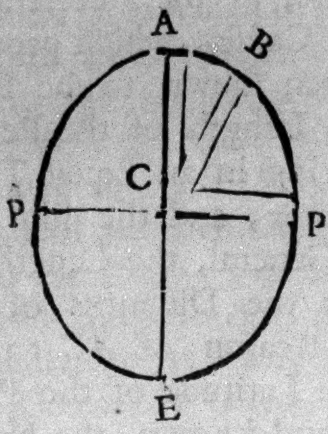
The Doctrine of Pendulums, as apply'd to Determine the Figure of the Earth, which is ſaid to be

§. 15. To conclude this Doctrine of Pendulums, we ſhall conſider, what is alledg'd concerning them, in the preſent Celebrated Philoſophy, to Determine the Figure of the Earth, that is, what Proportion it's Axis bears to the Diameter, Tranſverſe or Perpendicular to it;

Let

that of a Spheroeid, Explain'd and Conſider'd. Sir Iſ. Newt. Princip. Prop. 19, 20. Lib. 3. Dr. Gregory's Aſtronom. Prop. 52. Lib. 3.

Let the Figure *APEp*, whoſe Center is *C*, Repreſent the Earth, *Pp* it's Axis, *AE* any Diameter of the Æquator, Perpendicular to the Axis; Let the Lengths of the Pendulums be Meaſur'd, which Oſcillate in the Places *A* and *P*, in a Cyclois, in a Given Time, and *AC*, *PC*, will be Reciprocally as the ſaid Lengths of the Pendulum, and therefore in a known Proportion; ſo likewiſe in any Intermediate Place, *AC*, *BC*, will be Reciprocally, as the Lengths of the Pendulums, which Oſcillate in a like Space of Time in the Places *A* and *B*, and therefore in a known Proportion.

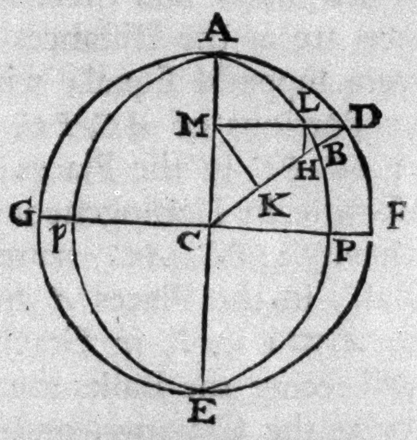


For let *ACP* be conceiv'd to be an Inflected Siphon or Canal, full of a Fluid and Homogeneous Matter; from the Quieſcence of the Fluid it is Evident, that it is in an Æquilibrium in both the Crura, *AC*, *PC*, the Centrifugal Force from the Motion of the Earth about it's Axis, and the Greater Diſtance from the Center of the Earth, Raiſing and Supporting the Fluid, in the Crus *CA*, to a Greater Height, than in that of *CP*; from whence any Portion of the Fluid in *CA* is in an Æquilibrium, or is Equally Heavy, with a like Portion, and alike Situated, of the Fluid in *CP*, which therefore is True of any other Homogeneous Bodies, tho' they are not Fluid; The uppermoſt Points *A* and *P* of the Crura are alike Situated, and conſequently the Homogeneous Bodies, in *A* and *P*, which are as *AC*, *PC*, have an Equal Gravity towards the Center of the Earth; But the Gravity of a Body in *A*, which is as *PC*, is to the Gravity of another Body in *A*, that is Homogeneous to the Former, and which is as *AC*, as *PC* to *AC*, that is, the Weights of Homogeneous Bodies, in a near Situation to each other, are as the Bodies or the Bulks of them, and therefore the Gravities of Homogeneous Bodies, which are Equal and Situate in *A*, and *P*, are as *PC* to *AC*, that is Reciprocally, as the Diſtances from the Center; for ſuppoſing *AC*.*PC*::100.1, ſince *AC*, *PC*, or *A* and *P*, Gravitate Equally, a Part of *AC* Equal to *PC*, or a Part of *A* Equal to *P*, will Gravitate a Hundred Times leſs, or it's Gravity in Reſpect of *P*, will be as 1 to 100; By a like Reaſoning it may be ſhewn, that the Gravity of a Body in *B*, is to the Gravity of an Equal and Homogeneous one in *P*, as *CP* to *CB*; from whence *ex Æquo* the Gravities of Equal and Homogeneous Bodies, whereſoever they are on the Superficies of the Earth, are Reciprocally, as their Diſtances from the Center; But the Accelerating Gravity of a Body is, as it's Abſolute Gravity divided by it's Bulk, and therefore the Accelerating Gravities of Bodies on the Earth's Surface are as the Diſtances of the Places from the Center Inverſely, becauſe the Bulks were ſuppos'd Equal; which may be thus Compriz'd in ſhort; Let *A* and *P* be Similar Portions of *AC*, *PC*, ſince *AC* = *PC* in Gravity, *A* = *P* in Gravity, but the Bulks :: *AC*.*PC* in the Places *A* and *P*, (and what is ſaid of Homogeneous Fluids obtains likewiſe in Homogeneous Solids;) On the other Hand in the ſame Place *A*, *P*.*A* in Gravity :: *PC*.*AC*, namely, the Weights are as the Bulks, if therefore, *A* = *P* in Bulk, in the Places *A* and *P*, *A*.*P* in Gravity :: *PC*.*AC*; for Inſtance, if 100 Parts in *A*, = 1 in *P*, in Gravity, 1 Part in *A* will Gravitate 100 Times leſs than 1 in *P*; and ſeeing the Bulks are ſuppos'd Equal, the Accelerating Forces, in *A* and *P*, will be as the Gravities, and therefore :: *PC*.*AC*, or Reciprocally, as the Diſtances from the Center.

Farther, Since the Oſcillation of the Pendulous Body at *A*, in a Cyclois, is ſuppos'd, from Obſervation, to be perform'd in the ſame Time with the Oſcillation of another Body at *P*, in a Cyclois, and by Prop. 25. Part 2. *Horolog. Oſcillator.* The Time of the Deſcent, thro' the Axis of the Cyclois, is in a Given Proportion to the Time of Oſcillation in the ſaid Cyclois, namely, as the Diameter of a Circle to it's Circumference, and by Prop. 6, 7. Part 3. The Axis of the Cyclois, which the Pendulous Body Deſcribes, is in a Given Proportion to the Length of the Pendulum, Namely, as 1 to 2, and therefore the Time of the Deſcent, thro' the Axis of the Cyclois, is in a Given Proportion to the Time of the Deſcent, thro' the Length of the Pendulum, that is, in a Subduplicate Reaſon of the Former, the Times or Celerities of Deſcent being in a Subduplicate Reaſon of the Spaces Deſcrib'd; It will be Conſequent, that the Time of Deſcent, thro' the Length of the Pendulum at *A*, will be Equal to the Time of Deſcent, thro' the Length of the Pendulum at *P*, ſince the Times of Oſcillation in both the Pendulums are Equal, and they have, both of them, the ſame Given Reaſons to the Times of Deſcent thro' the Lengths of 'em.

But the Spaces perform'd at *A* and *P* in Equal Times are, as the Accelerating Forces or Gravities in the ſaid Places, or the Effects are, as the Cauſes, which produce them, and the ſaid Accelerating Forces or Gravities have been ſhewn to be Reciprocally, as the Diſtances from the Center, and therefore the Length of the Pendulum at *A*, is to the Length of the Pendulum at *P*, Oſcillating in an Equal Time, as *PC* to *AC*, or Reciprocally, as the Diſtances from the Center; and the like may be Demonſtrated of any other Point, as *B*, and therefore in General, the Lengths of Pendulums, Oſcillating in Equal Times, are Reciprocally, as the Diſtances of the Places from the Center of the Earth; Since therefore the Reaſon of *AC* to any other Diſtance *BC*, and the Inclination of *BC* to *AC*, or the Latitude of the Place, and the Reaſon of *AC* to *PC*, in Particular, are found out and known, the Nature of the Figure *APEp* is Determin'd, to wit, the Section of the Earth with the Plane of the Meridian, which Revolv'd upon the Axis *Pp* will produce the Earth's Figure.

If we have a Mind to Determine the Figure of the Earth by the foregoing Method, it is not neceſſary to have a Meaſur'd Length of a Pendulum, Oſcillating in a Given Time, at the very Pole it ſelf *P*, becauſe, by ſeveral Lengths obſerv'd in Different Latitudes, it may be ſafely concluded, what the Length of the Pendulum will be, which Oſcillates in the ſame Given Time at the Pole; Again, in order to ſolve this Problem, it is not neceſſary in Different Places ſo to adjuſt the Pendulum, that it ſhou'd perform it's Oſcillations in the ſame Time; 'tis enough to take a Pendulum, and adjuſt it ſo to one Place, that it ſhall perform it's Oſcillations in a Time Given, and then Transfer it into other Places, and Mark how much the Clock, to which the ſaid Pendulum is affix't for a Balance, is Retarded or Accelerated in the Time of one Revolution of a fixt Star to the ſame Place, as the Places, into which it is Transfer'd, are nearer to the Æquator or the Pole, than that to which the Automaton or Clock is adjuſted, and from that Retardation or Acceleration to compute what Length of the Pendulum is Requiſite to perform the Oſcillations in the ſame Time, in which they were perform'd in the Place, to which the Pendulum was originally Adapted.



From what is above Demonſtrated, it is Collected, ſuppoſing all Things, as before, and *AGEF* to be a Circle drawn Round the preceding Figure, that *DB* is, as the Increment of the Accelerating Gravity, as we Remove from the Æquator towards either of the Poles, or, as the Increment in the Place *B* above the Length of the Pendulum, which Oſcillates at the Æquator in a Given Time; for *AC* Repreſents the Accelerating Gravity, or the Length of the Pendulum, at the Pole *P*, and *CP* the Accelerating Gravity, or the Length of the Pendulum, Oſcillating in an Equal Time, at the Æquator *A*, and therefore *PF* will Repreſent the Increment of the Accelerating Gravity, or of the Length of the ſaid Pendulum, at the Pole *P*; In like Manner, *CB* Repreſents the Accelerating Gravity, or Length of the Pendulum, at *A*, and $AC = DC$, the Accelerating Gravity, or Length of the Pendulum, at *B*; and conſequently, *DB* will Repreſent the Increment of the Accelerating Gravity, or of the Length of the Pendulum, at *B*, above the Accelerating Gravity, or Length of the Pendulum Oſcillating in the ſame Time at *A*.

And from hence, by a Geometrick Reaſoning, it is Prov'd, that ſuppoſing *APEp*, a Section of the Earth with the Plane of the Meridian, to be an Ellipſis, the Increments of the Accelerating Gravity, in Different Places of the Earth's Surface, above the Accelerating Gravity, or the Length of the Pendulum, at the Æquator, is very nearly in a Duplicate Reaſon of the Right Sines of the Latitudes of thoſe Places, that is, for Inſtance, *PF* is to *BD* in a Duplicate Reaſon of *CF* to *MD*, or *PF*.*BD*::*CFq*.*MDq*, and the ſame may be ſhewn of any other Points or Places, or Latitudes, as well as of *P* and *B*; The Demonſtration is too Tedious here to Inſert, but is eaſily Apprehended by Mathematicians.

It muſt be yet Obſerv'd, that what foregoes is True upon the Suppoſition, and *ex Hypotheſi*, that the Earth conſiſts of an Equally Denſe and Uniform Matter, ſince the Fluid, with which the Canals, *ACP*, *BCP*, Fig. 1. were Repleniſh'd, was preſum'd to be Uniform and Homogeneous; but if the Matter, of which the Earth conſiſts, is Denſer towards the Center, than nearer to it's Surface, the aforeſaid Increments of the Diſtances from the Center, by Retiring from the Poles to the Æquator, and Proportional to theſe Diſtances the Increments of the Accelerating Gravity, and the Length of the Pendulum, Oſcillating in a Given Time, by Retiring from the Æquator to the Poles, will be Greater, than what is Aſſerted in the above-mention'd Computation, and the Axis of the Earth will be Leſs, in Reſpect of the Diameters Perpendicular to it; for, if that Matter towards the Center, by which the Earth is there Denſer, is taken away and conſider'd apart, ſo that the Remaining Matter ſhou'd be Equally Denſe, it is Evident, by what has been alledg'd, that the Accelerating Gravity in Different Places of this Equally-Denſe Earth's Surface is Reciprocally Proportional to the Diſtance from the Center; But the ſaid Accelerating Gravity is farther Increas'd by the Addition of the Redundant Matter about the Center, and very nearly, by what has been before Demonſtrated in this Philoſophy, in a Reciprocal Duplicate Proportion of the Diſtance from it.

Since therefore, where we ſuppoſe the Earth Uniformly Denſe, it's Surface is Elevated towards the Æquator, and Depreſs'd towards the Pole, and ſince the Accelerating Gravity at the Æquator, is Leſs than at the Pole, in Proportion of the Diſtance of the Pole from the Center to the Semidiameter of the Æquator, and moreover, ſince the Accelerating Gravity to the Redundant Matter about the Center is Leſs at the Æquator than at the Pole, in a Duplicate Reaſon of the Diſtance of the Pole from the Center to the Semidiameter of the Æquator, which is Leſs than the Former ſimple Reaſon, being a Reaſon of a leſs Inequality, it follows, that, where we ſuppoſe the Earth Denſer towards the Center, the Accelerating Gravity, compounded of both the Former, is Leſs at the Æquator than at the Pole, in a leſs Reaſon, than that of the Diſtance of the Pole from the Center to the Semidiameter of the Æquator; and conſequently, from this leſs Accelerating Gravity at the Æquator, in Reſpect of that at the Poles, the Earth will be more Elevated at the Æquator, than what the preceding Doctrine of an Earth Equally Denſe wou'd Require, which, by the Calculations of this Philoſophy, and ſuppoſing a Mile conſiſts of 5000 Feet, wou'd be $17\frac{1}{6}$ Miles, but if the Earth is Denſer towards the Center, $31\frac{7}{12}$, and therefore the Earth will be nearly Spherical, but Properly and Truly a Spheroeid; The ſame likewiſe obtains in the Length of a Pendulum, Oſcillating in a Given Time, which has been ſhewn to be Proportional to the Accelerating Gravity; namely, where the Earth is ſuppos'd to be Denſer towards the Center, the Length of the Pendulum Oſcillating in a Given Time, is Leſs at the Æquator than at the Pole, in a leſs Reaſon, than that of the Diſtance of the Pole from the Center to the Semidiameter of the Æquator.

§. 16. And from hence this Philoſophy proceeds to Determine the Proportion, which the Axis of the Sun or any Given Planet has to the Diameters, which are Perpendicular to it.

How the ſame Doctrine is Extended to the Sun and the Planets.

First of all let the Proportion be found of the Centrifugal Force in the Middle Circle, betwixt the Poles of the Sun or the Planet Given, to the Centrifugal Force in the Æquator of the Earth, which is done by this Propoſition, that the Centripetal or Centrifugal Forces are Reciprocally, as the Squares of the Periodick Times divided by the Radius's of the Circles; But the Proportion betwixt the Centrifugal Force in the Æquator of the Earth, to the Gravity on the Earth's Surface, is Given, which is, as the Exceſs of the Earth's Diameter at the Æquator to it's Axis, ſince, by the preceding Propoſition, that Exceſs ariſes from the Centrifugal Force alone, and therefore is Proportional to it; and the Proportion of Gravity on the Earth's Surface to the Gravity on the Sun's Surface, or of the Planet Given, is known by that Propoſition, which aſcertains the Proportion of the Quantity of Matter in the Sun, to the Quantity of Matter in any Primary Planet; that is, if the Matter of Two Globes, Gravitating to each other, is Homogeneous in Places Æquidiſtant from the Centers,

Sir Iſ. Newt. Princip. Prop. 4. Corol. 1. Lib. 1.
Sir Iſ. Newt. Princip. Prop. 8. Lib. 3.
Dr. Gregory's Aſtronom. Prop. 48. Lib. 3.

Centers, the Weight of one Globe to the Other will be Reciprocally, as the Square of the Diſtance betwixt the Centers, ſuppoſing them to be Remov'd at Various Diſtances from each other; and conſequently, the Proportion, which is Compounded of theſe Given ones, will be likewiſe Given, to wit, the Proportion, which the Centrifugal Force in the Middle Circle betwixt the Poles of the Sun or Planet Given, has to the Gravity on it's Surface, and is the ſame, as the Exceſs of the Diameter of the Æquator of the Sun or Planet above it's Axis, to the ſaid Axis, and therefore the Proportion betwixt the Sun's or Planet's Axis, and it's Diameter Perpendicular to that Axis, will be Determin'd.

Sir Iſ. Newt. Princip. Prop. 18. Lib. 3.

AND in General it is form'd into a Propoſition, that the Axes of the Planets are Leſs than the Diameters, which are Perpendicular to them; Becauſe, tho' the Planets ought to be of a Spherical Figure, Abſtracting from their Circular Motion Round their Axes, upon the Account of the Equal Gravitation of the Parts on all Hands to the Center, yet by that Circular Motion it comes to Paſs, that the Parts Retiring from the Axes, endeavour to Aſcend towards the Æquators, and therefore the Matter, if it is Fluid, by ſuch Aſcent will Increaſe the Diameters, at the Æquators, and by it's Deſcent Diminiſh them at the Poles; Thus the Diameter of *Jupiter*, by the Agreement of the Obſervations of Aſtronomers, is found to be Shorter betwixt the Poles, than from Eaſt to Weſt; and by the ſame Argument, unleſs our Earth was Higher at the Æquator than under the Poles, the Seas wou'd ſubſide at the Poles and Aſcend towards the Æquator, and there Cauſe an Univerſal Inundation, namely, by the Earth's Revolution, and by the Parts of it thereupon Retiring from it's Axis towards the Æquator.

The Table Conſtructed upon the foregoing Doctrine. Sir Iſ. Newt. Princip. Prop. 20. Lib. 3. Edit. 2.

§. 17. FURTHERMORE, in Reſpect of Pendulums, Oſcillating in a Second of Time, a Table is Calculated of the ſeveral Lengths of them in Various and Different Latitudes, from no Degrees Latitude under the Æquator to 90 under the Poles, upon the foregoing Hypotheſis, that the Earth is uniformly Denſe, and from the Reaſonings upon that Hypotheſis, which have been before Explain'd, and particularly from this Theorem, that the Increment of Gravity, by Proceeding from the Æquator to the Poles, is as the Square of the Right Sine of the Latitude very nearly, as alſo, that the Lengths of Synchronal Pendulums, that is, which Oſcillate, in Equal Times, in Different Places or Latitudes, are as the Accelerating Gravities in thoſe Places or Latitudes; From whence the Following Table is Computed, in which a Line is the *12th* Part of an Inch.

Latitude of the Place.	Length of the Pendulum.		Latitude of the Place.	Length of the Pendulum.	
Degrees.	Feet .	Lines.	Degrees.	Feet .	Lines.
0	3	. 7,468	46	3	. 8,461
5	3	. 7,482	47	3	. 8,494
10	3	. 7,526	48	3	. 8,528
15	3	. 7,596	49	3	. 8,561
20	3	. 7,692	50	3	. 8,594
25	3	. 7,811	55	3	. 8,756
30	3	. 7,948	60	3	. 8,907
35	3	. 8,099	65	3	. 9,044
40	3	. 8,261	70	3	. 9,162
41	3	. 8,294	75	3	. 9,258
42	3	. 8,327	80	3	. 9,329
43	3	. 8,361	85	3	. 9,372
44	3	. 8,394	90	3	. 9,387
45	3	. 8,428			

FROM this Table it is ſaid to be manifeſt, that in Geographical Matters the Earth may be Eſteem'd as Spherical, and that the Inequality of it's Diameters, which is but ſmall, may be more Eaſily and Certainly found out, and Determin'd by the Experiments of Pendulums than by the Eclipſes of the Moon or any other Way. It is likewiſe Conſtructed upon the Hypotheſis, that the Earth is uniformly Denſe, but if it's Matter is Denſer nearer the Center than at the Surface, for the Reaſons alledg'd above the Differences of the Pendulums will be ſomething Greater, than what are Expreſs'd in the foregoing Table; becauſe, tho' Gravity is Reciprocally, as the Diſtance of the Weight from the Center, where the Earth is uniformly Denſe, it will yet be compounded of another Proportion, which will be Reciprocally, as the Square of the Diſtance from the Redundant Matter, and therefore Gravity under the Æquator is leſs to that Redundant Matter, than in the preceding Computation, and the Earth will riſe Higher, and it's Surface be more Elevated, by this Defect of Gravity, and the Exceſs of the Lengths of the Pendulums at the Poles will be Greater, than what is before Defin'd.

The Experiments alledg'd to Prove the Truth of the Preceding Table.

§. 18. Thus far is Reaſon'd and Hypotheſes are Invented, and to Confirm this from Experience, it is told us, that certain Aſtronomers, who have been ſent into Foreign Parts, on purpoſe to make Aſtronomical Obſervations, have found, that the Pendulums of Clocks move Slower, nearer the Æquator, than the Poles, and that the firſt Perſon, who took Notice of this, was Mr. *Richer* in the Year 1672, and in the Iſland *Cayenne*, for, whilſt he obſerv'd the Paſſage of the fixt Stars by the Meridian, in the Month of *Auguſt*, he found the Pendulum of his Clock to move Slower, than according to the Middle Motion of the Sun, with a Difference of $2'.28''$ every Day; he afterwards made a Single Pendulum, which ſhou'd Oſcillate in a Second of Time, by the Beſt Pendulum Clock that cou'd be had, and mark't the Length of this Single Pendulum, and this he did frequently every Week for Ten Months together; Then Returning to *France*, he compar'd the Length of this Pendulum with the Length of an Iſochronal Pendulum at *Paris*, which was Three *Paris* Feet, and Eight Lines, with Three Fifth Parts of a Line, and found it Shorter with the Difference of one Line, and one Fourth of a Line; But by the Slowneſs of the Pendulum-Clock in *Cayenne*, the Difference of the Pendulums is Inſer'd by Computation to be one Line and an Half.

Dr. *Halley* in the Year 1677, at the Iſland of St. *Helen's*, found his Pendulum-Clock to move Slower than at *London*, but did not obſerve the Difference, he yet made his Pendulum Shorter by more than an Eighth Part of an Inch, or one Line and an Half.

In the Year 1682, Mr. *Varin* and Mr. *Des Hayes* found the Length of the Pendulum, Oſcillating in a Second of Time, to be, in the Royal Obſervatory at *Paris*, 3 Feet and $8\frac{5}{9}$ Lines, and in the Iſland of *Goreè*, by the ſame Method, they found the Length of a Synchronal Pendulum to be 3 Feet and $6\frac{5}{9}$ Lines, and the Difference of the Lengths therefore 2 Lines; And in the ſame Year, at the Iſlands *Guadaloupe* and *Martinico*, they found the Length of a Synchronal Pendulum to be 3 Feet and $6\frac{1}{2}$ Lines.

Afterwards in the Year 1697, in the Month of *July*, Mr. *Couplet* the Son Adjuſted his Pendulum-Clock to the Middle Motion of the Sun in the Royal Obſervatory at *Paris*, in that Manner, that the Clock Exactly Agreed with the Sun's Motion for a long Space of Time: Then Sailing to *Lisbon*, he found, in *November* following, that his Clock went Slower than before, the Difference being $2'.13''$ in 24 Hours, and, in the Month of *March* after, Sailing to *Paraiba*, he there found his Clock went Slower, than at *Paris*, $4'.12''$, in 24 Hours; and he Affirms, that the Pendulum, Oſcillating in Seconds of Time, was at *Lisbon* $2\frac{1}{2}$, and at *Paraiba* $3\frac{2}{3}$ Lines Shorter than at *Paris*, tho' it is ſaid, he ſhou'd Rather have made the Differences of the Lengths of the Pendulum $1\frac{1}{3}$ and $2\frac{5}{9}$ Lines, as better Correſponding with the Differences of the Times of Oſcillation, $2'.13''$ and $4'.12''$, But, it is told us, theſe Obſervations are too Groſs to be Rely'd on.

In the Years 1699 and 1700, Mr. *Des Hayes*, Sailing again to *America*, Determin'd the Length of the Pendulum, Oſcillating in Seconds of Time, in the Iſlands of *Cayenne* and *Granada* to be ſomething Leſs than 3 Feet and $6\frac{1}{2}$ Lines, in the Iſland of St. *Chriſtopher's* to be 3 Feet and $6\frac{3}{4}$ Lines, and in the Iſland of St. *Dominick* 3 Feet and 7 Lines.

In the Year 1704, *Feuellè* found the Length of the Pendulum, Oſcillating in Seconds of Time, in *Portobel* in *America*, to be 3 *Paris* Feet and only $5\frac{7}{12}$ Lines, that is, 3 Lines Shorter than at *Paris*, but there was an Error in the Obſervation, for afterwards Sailing to the Iſland *Martinico*, he found the Length of an Iſochronal Pendulum to be only 3 *Paris* Feet and $5\frac{10}{12}$ Lines.

But the Latitudes of the Places above-mention'd are as follow, of *Paraiba* 6°.38′ Southern, of *Portobel* 9°.33′, and of the Iſlands *Cayenne*, *Goreè*, *Guadaloupe*, *Martinico*, *Granada*, St. *Chriſtopher*'s, St. *Dominick*'s, Reſpectively 4°.55′, 14°.40′, 14°.0′, 14°.44′, 12°.6′, 17°.19′, and 19°.48′ Northern, and we may add *Lisbon* about 40°.

The Exceſſes of the Length of the Pendulum at *Paris* above the Lengths of Iſochronal Pendulums, obſerv'd in theſe ſeveral Latitudes, are ſomething Greater than according to the foregoing Table, and therefore the Earth is ſomewhat Higher under the Æquator, than that Calculation makes it, which proceeds upon the Earth's being uniformly Denſe; and conſequently, the Earth is Denſer towards the Center, than nearer to the Surface, unleſs the Heats in the Torrid Zone may give ſome Addition to the Length of the Pendulums.

For Mr. *Picart* obſerv'd, that the Iron-Rod of the Pendulum, which, in Winter-Time and Froſty Weather, was in Length one Foot, being Warm'd and Heated at the Fire, became one Foot and one fourth of a Line.

And Mr. *De la Hire* afterwards obſerv'd, that an Iron-Rod, which, in Winter-Time and Froſty Weather, was ſix Feet in Length, when Expos'd to the Sun's Heat, was ſix Feet and two Thirds of a Line: In the Former Caſe, the Heat was Greater than in the Latter, and in the Latter, Greater than the Heat of the External Parts of an Human Body; For Metals grow exceeding Warm by the Sun's Heat in Summer; But the Pendulum of a Clock is never wont to be Expos'd to the Heat of the Summer's Sun, and therefore never admits of an Heat, Equal to that of the External Parts of an Human Body, and conſequently, the Rod of a Pendulum, in a Clock, three Foot Long, will be ſomething Longer in Summer than in Winter, tho' the Exceſs will ſcarcely be more than one fourth Part of a Line; from whence it is ſuppos'd to Follow, that the whole Difference of the Length of Iſochronal Pendulums, in Various Latitudes, cannot be Aſcrib'd to a Difference of Heat; Nor can this Difference be Attributed to the Errors of theſe Aſtronomers in their Obſervations; for albeit, they do not perfectly Agree, yet the Errors are ſo Minute, that they may be juſtly Neglected and Slighted; and in this they Entirely Conſent, that Iſochronal Pendulums are Shorter under the Æquator than at the Royal Obſervatory in *Paris*, the Difference being about Two Lines or the ſixth Part of an Inch; By the Obſervations of Mr. *Richer* in *Cayenne*, the Difference was one Line and a Half, the Error of Half a Line is eaſily Committed; Mr. *Des Hayes*, by his Obſervations in the ſame Iſland, Corrected that Error and found the Difference to be $2\frac{1}{18}$ Lines; Moreover by the Obſervations made in the Iſlands of *Goreè*, *Guadaloupe*, *Martinico*, *Granada*, St. *Chriſtopher*'s, and St. *Dominick*, and Reduc'd to the Æquator, the Difference was not Leſs than $1\frac{19}{20}$ Line, nor Greater than $2\frac{1}{2}$ Lines, and the Middle Quantity betwixt theſe Two Limits is $2\frac{9}{40}$ Lines, Take away the $\frac{9}{40}$ of a Line on Account of the Heats in the Torrid Zone, and there will Remain the Difference of 2 Lines.

Wherefore, ſince that Difference by the Preceding Table, which is Calculated upon the Suppoſition of the Earth's being uniformly Denſe, is only $1\frac{87}{1000}$ Line, the Exceſs of the Earth's Height at the Æquator above that at the Poles, which was $17\frac{1}{6}$ Miles, being now Increas'd by an Increaſe of the Differences of the Lengths of the Pendulums, will be $31\frac{7}{12}$ Miles; for the Slowneſs of the Pendulum under the Æquator Evinces and Proves a Defect of Gravity, and by how much Lighter the Matter of the Earth is, by ſo much Greater ought to be it's Height, that it may ſupport by it's Weight the Matter under the Poles in an Æquilibrium; And from hence the Figure of the Earth's Shadow, Determin'd by the Eclipſes of the Moon, will not be exactly Circular, but it's Diameter from Eaſt to Weſt will be Greater than that from North to South, by an Exceſs of about 55″, and the Greateſt Parallax of the Moon in Longitude will be ſomething Greater than it's Greateſt Parallax in Latitude, and the Greateſt Semidiameter of the Earth will be 19767630 *Paris* Feet, the Leaſt 19609820, and the Middle 19688725 Nearly.

We ſhall here ſubjoin a Table of the Differences of the Lengths of Iſochronal Pendulums, according to what they were found by the foregoing Obſervations, and then Compare them with the Preceding Table, which was form'd from Calculation, after we have Inquir'd into the Hypotheſes and Principles, upon which it was Made and Contriv'd.

	Northern Latitude.		Length of the Pendulum in Feet and Lines.
	Cayenne	4°·55′	*Richer.* *Newton.* *Des Hayes.* $3 \cdot 7\frac{7}{20}$. $3 \cdot 7\frac{1}{10}$. $3 \cdot 6\frac{1}{2}$. ſomething Leſs. 3·7,350. 3·7,100. 3·6,500.
South. Latitude.	*Paraiba*	6·38	*Couplet* Groſs Obſerver. *Newton.* $3\frac{2}{3}$ Lines Leſs than at *Paris*, $2\frac{5}{9}$ Lines Leſs.
	Portobel	9·33	*Feuellè.* $3 \cdot 5\frac{7}{12}$. 3·5,583.
	Granada	12·6	*Des Hayes.* $3 \cdot 6\frac{1}{2}$. ſomething Leſs. 3·6,500.
	Guadaloupe	14·0	*Varin, Des Hayes.* $3 \cdot 6\frac{1}{2}$. 3·6,500.
	Goreè	14·40	*Varin, Des Hayes.* $3 \cdot 6\frac{5}{9}$. 3·6,555.
	Martinico	14·44	*Varin, Des Hayes.* *Feuellè.* $3 \cdot 6\frac{1}{2}$. $3 \cdot 5\frac{10}{12}$. 3·6,500. 3·5,833.
South. Latitude.	St. *Helen's*	15·0	*Halley.* $1\frac{1}{2}$ Line Leſs than at *London.*
	St. *Chriſtopher's*	17·19	*Des Hayes.* $3 \cdot 6\frac{3}{4}$. 3·6,750.
	St. *Dominick*	19·48	*Des Hayes.* 3·7.
	Lisbon	40·0	*Couplet* Groſs Obſerver. *Newton.* $2\frac{1}{2}$ Lines Leſs than at *Paris*, $1\frac{1}{3}$ Line.
	Paris	48·45	*Richer.* *Varin, Des Hayes.* *Couplet.* $3 \cdot 8\frac{3}{5}$. $3 \cdot 8\frac{5}{9}$. $2\frac{1}{2}$ Lines More than at *Lisbon*, 3·8,600. 3·8,555. $3\frac{2}{3}$ More than at *Paraiba.*
	London	51·30	*Halley.* $1\frac{1}{2}$ Line More than at St. *Helen's.*

§. 19. In Anſwer to all this Doctrine of Meaſuring the Diameters of the Earth by the Lengths of the Pendulum, and thereby Determining the Figure of the Earth; We muſt First ſay, that the Principles are Wrong and Falſe upon which this Philoſophy Proceeds, and Then the Concluſions from the Experiments brought to Confirm them; And First, the Demonſtration, that the Lengths of Pendulums Oſcillating in Equal Times are Reciprocally, as the Diſtances from the Earth's Center, is by no Means rationally Evinc'd; Becauſe First, it is ſuppos'd, that the Earth Conſiſts of an Homogeneous Matter, which is not Prov'd; And Second, that whatever is ſhewn of an Homogeneous Fluid, Equally obtains in Homogeneous Solids, in the Preſent Caſe, which is likewiſe far from being Evident; And Third, that the Preſent Doctrine of Hydroſtaticks is Unqueſtionable, which again is not Manifeſt.

The Demonſtration it ſelf of the Lengths of Pendulums, Oſcillating in Equal Times, being Reciprocally as the Diſtances from the Earth's Center not prov'd upon the Suppoſition, that the Earth is Equally-Denſe.

As to the First, if the Matter of Mold, Clay, Stone, Metals, and a Thouſand Bodies more, of which the Earth Conſiſts, is Various in it's Proper and Internal

Forces, and cannot be Conſider'd as a Similar and Uniform Subſtance, all this Reaſoning falls to the Ground, and till that Point is Clear'd, remains Diſputable and Doubtful; Since, if Matter is Different in it's Forces, the Weights of Bodies will not be, as the Bulks of them, nor the Gravities of Bodies, which are Equal and Situate in *A* and *P*, as *PC* to *AC*, that is Reciprocally, as the Diſtances from the Center, upon which Maxim yet this Whole Demonſtration Depends. See §. 15. Fig. 1.

As to the Second, That Fluids and Solids come under one Denomination in the preſent Caſe, becauſe they Gravitate a-like to the Center of the Earth, and therefore, that a Canal of Solid Matter Extended to the Center, or one half Fluid and the other half Solid, is the ſame, as a Canal of Fluid Matter Extended to the Center, is to aſſume a great Deal without any Proof or Eviction of the Thing; becauſe, tho' all Matter was Homogeneous and had an Equal Force of Gravitation in it ſelf, which is not True, yet it muſt be Confeſs'd, that there is a wide Difference betwixt Matter's being left at Liberty to Exert that Force, as in Fluids, and being Reſtrain'd from doing it by a firm Adheſion of Parts, as in Solids; For whoever Imagin'd before, that a Column of Solid Matter might be Balanc'd by a Column of Fluid, in the Way, and according to the Laws of Hydroſtaticks? When it is Plain, that a Column of Solid Matter, drawn from the Surface of the Earth to the Center, beſides it's Force of Gravitation, has alſo a Force of Coheſion, which can be Reduc'd to no Rules of a Balance, ariſing from mere Gravitation, which is the Caſe of Fluids, and which, it is ſuppos'd, may be ſo Reduc'd.

As to the Third, That the Common Hydroſtaticks are Preſum'd to be Demonſtrated, we muſt ſay, that neither is That in fact True; becauſe the Laws and Rules of Hydroſtaticks are Prov'd upon the Suppoſition, that Nothing is to be Conſider'd in Fluids, excepting their Specifick Gravities, whereas it is Certain, that there are ſome Fluids, which are Specifically Heavier than others, and which yet, by the Spirituouſneſs or the Expanſive Force of them, will Riſe in thoſe, which are Specifically Lighter; Beſides which, we muſt affirm, that, in all Fluids, their Proper Expanſive and Contractive Forces are to be Conſider'd, and not their Specifick Gravities only.

Moreover Fourthly, Granting every Thing, which this Philoſophy Requires or Demands, it is ſomething Extraordinary, that it ſhou'd here Endeavour to Demonſtrate, that the Accelerating Gravities are Reciprocally, as the Diſtances from the Earth's Center, whereas Accelerating Gravity in General, and every other Action, is ſhewn to be Reciprocally, as the Squares of thoſe Diſtances, by this Philoſophy, and is a Truth afterwards aſſum'd, as Prov'd, in this very Propoſition, when it comes to Treat of the Redundant Matter, ſuppoſing the Earth not to be uniformly Denſe; upon all which Accounts it is not Prov'd, that the Accelerating Gravity in *A* is to that in *P*, as *PC* to *AC*. See §. 15. Fig. 1.

See §. 15. Fig. 1. Again, If now we take Two Bodies and place them in *A*, it is ſaid, *P . A* : : *PC . AC*, that is, the Gravities will be as the Bulks; which, as before, ſuppoſes, that in Matter nothing is to be Conſider'd, excepting an uniform Gravity, and the Number of Parts in each Body, which are Accelerated by it, and conſequently, that Matter has no peculiar Expanſive or Contractive Forces, which is once more Deny'd, and till it is Prov'd, it has not, This Demonſtration is, for that Reaſon, as we have already Declar'd, Imperfect and Defective.

See §. 15. Fig. 1. The next Part of this Demonſtration concerns the Nature of Pendulums, which we have before particularly Examin'd, and therefore the Objections, which lie againſt the Explanation of that Doctrine, are Equally Valid againſt the Truth of the Preſent Propoſition; Namely, that it is nothing more than an Abſtracted Reaſoning, is not juſtify'd by Fact and Experiment, and that, what is ſo, Admits of a Different Solution, from what is Given by theſe Principles; what we ſhall farther obſerve here is this, that the Lengths of the Pendulums are affirm'd to be, as the Accelerating Forces or Gravities, which are made to be Reciprocally, as the Diſtances from the Earth's Center; we have ſhewn, there is a Difference betwixt Bodies Deſcending by Gravity, and Oſcillating in a Pendulum, and conſequently, this alſo is a Notion not Prov'd, but Aſſum'd; As to what Follows, it ſo entirely depends upon what foregoes, that there is no Occaſion to take any particular Notice of it, Namely, that the Increments of the Accelerating Gravity, in Different Places of the Earth's Surface, above the Accelerating Gravity, or the Length of the Pendulum at the Æquator, are very nearly in a Duplicate Reaſon of the Right Sines of the Latitudes of thoſe Places, becauſe it ſhows more of the Skill of the Geometer, than the Sagacity or the Truth of the Philoſopher; I ſhall only add, that, as any one wou'd be Aſtoniſh'd to Think, how it was poſſible to contrive a Way, to find out the Diameters of the Earth, by the Oſcillations of a Pendulum, ſo he may leave off that Admiration, when he ſees the Strange and Unaccountable Methods taken to do it; he will rather Wonder, that Men ſhou'd enter into ſuch Conceits, than be ſurpriz'd at the Greatneſs of the Performance; as will yet farther Appear in the Progreſs of this Examination.

See §. 15. Fig. 2.

That the Earth is Denſer towards the Center not Prov'd, nor the Reaſonings upon it Concluſive.

See § 15. Fig. 2.

§. 20. Thus far is ſaid to be Demonſtrated, ſuppoſing the Earth is uniformly Denſe, but if it be not ſo, and it is Denſer near the Center, and Rarer at the Surface, as is Generally Conceiv'd, the foregoing Proportion muſt be Alter'd, and the Accelerating Gravities, and the Lengths of the Pendulums, Analogous to Them, at the Æquator, and Poles, will be in a leſs Reaſon, than that of the Diſtance of the Pole from the Center to the Semidiameter of the Æquator, and this leſs Reaſon is Thought more Accurately to agree with the Experiments upon Pendulums than the Former and Greater: Let us then now ſee how the Caſe ſtands; Canals of Homogeneous Matter were Invented, in which Fluids and Solids ſhou'd be all one; Gravity was affirm'd to be Reciprocally, as it's Diſtance from the Center; Pendulums were made to Oſcillate according to the Will and Pleaſure of the Geometer, without any Proof that they did ſo; and the Earth was Imagin'd to be Equally Denſe, in order to Reduce the Diameters of it to ſome Proportion with the Lengths of the other; but all this not Availing, the Earth is now ſuppos'd not to be Equally Denſe, and to Compenſate for that Inequality, a Certain Maſs of Redundant Matter is Thruſt and Ramm'd to the Center, the Gravitation to which is pronounc'd to be Reciprocally, as the Squares of the Diſtances, whereas before Gravity was Reciprocally as the Diſtances: On the other Hand, that the Earth is Denſer at the Center than Nearer the Surface, whatever we may Surmiſe, is as much Unprov'd, as that it is Equally Denſe, or the Matter of it Homogeneous; ſome have affirm'd a Central Fire, and produc'd Arguments for it, and for what this Philoſophy Alledges, which is Nothing but it's own Authority, it may ſtill Remain a Queſtion; Allowing yet this Earth was Originally a Fluid, by which it might be Imagin'd, that Bodies ſubſided to the Center, according to their Specifick Gravities, and that the Earth therefore became Gradually Denſer from the Surface to the Center, Nothing ſtill of this is Certain or Demonſtrable; we find Bodies Promiſcuouſly plac'd, the Heavier above the Lighter, as well as the Lighter above the Heavier; and it is not Plain, that they may not be ſo Mixt and Confounded together, that there may be more Lighter Bodies, towards the Center, than Heavier, by mutual Coalitions and Coagmentations with one another, from whence their Natural Specifick Gravities might be Impeded in their Action; It is not farther Certain, taking all of Them together, the Gravity of the one with the Levity of the other, that they may not Conſtitute a Force of Gravitation, which may be pretty much Uniformly the ſame thro' the Whole; Likewiſe it is not prov'd, ſuppoſing a Gradual Increaſe of Denſity towards the Center, that a Maſs of Matter heap't about it, will have the ſame Effects as ſuch a Gradual Increment; and laſtly, there is Nothing allow'd to the Peculiar Forces of Matter in it's Expanſion and Contraction, which wou'd entirely Diſturb and Annull every Part of this Calculation, and yet, amidſt this vaſt Uncertainty of Things, a Matter uniformly Denſe or Increaſing in it's Denſity, in it's Approach to the Center, is Aſſum'd, as an Evident and Irreſiſtible Truth, and is accordingly made uſe of in this Demonſtration.

The Figure of the Sun and Planets not from hence Determin'd, nor yet their Denſities.

§. 21. Having from theſe Principles, however Precarious, Determin'd the Diameters of the Earth, and conſequently the Figure of it, This Doctrine goes on to Define the Figures and Diameters of the Sun or of any Planet Given.

See §. 16.

First, By Finding the Proportion of the Centrifugal Force in the Middle Circle, betwixt the Poles of the Sun or the Planet Given, to the Centrifugal Force in the Æquator of the Earth, from this Propoſition, that the Centripetal or Centrifugal Forces are Reciprocally, as the Squares of the Periodick Times divided by the Radius's of the Circles, which Propoſition we have afterwards Examin'd and Conſider'd, and ſhewn, it can be no Foundation, to build any certain Reaſonings in Nature upon.

SECOND, By Affirming, that the Proportion betwixt the Centrifugal Force, in the Æquator of the Earth, to the Gravity on the Earth's Surface, is Given, and that it is, as the Exceſs of the Earth's Diameter at the Æquator to it's Axis, ſince, by the preceding Demonſtration, that Exceſs is Produc'd from the Centrifugal Force alone, and therefore is Proportional to it; But ſeeing that Demonſtration is not Juſt, as we have now ſhewn, the Inference will be Equally Invalid.

THIRD, By Aſſerting, that the Proportion of Gravity on the Earth's Surface, to the Gravity on the Sun's Surface, or of the Planet Given, is known, by a Propoſition, which Aſcertains the Proportion of the Quantity of Matter in the Sun, to the Quantity of Matter in any Primary Planet, which is, if the Matter of Two Globes, Gravitating to each other, is Homogeneous in Places Æquidiſtant from the Centers, the Weight of one Globe to the Other will be Reciprocally, as the Square of the Diſtance betwixt the Centers, ſuppoſing them to be Remov'd at Various Diſtances from each other; which therefore depends upon this Preſumption, that all the Matter of the Earth, Sun, and Planets is Homogeneous and Similar, a Notion, which we have abundantly Confuted, in our Inquiry into the Principles of the Corpuſcular Syſtem, and in our Aſſertion of the Expanſive and Contractive Forces of Matter; and, for the ſame Reaſon, we cannot but Reject all the Subtle and Delicate Calculations of the ſeveral Denſities of the Sun and Planets, which are form'd upon that Hypotheſis, without any Demonſtrations, in Fact and Experience, of any of theſe Matters.

See Principles of Philoſ. and Chap. 5. of this Book.

That it is not Prov'd to be Matter of Fact and Experiment, that the Axes of the Sun, and of the Earth and Planets are Shorter than the Diameters Perpendicular to them.

§. 22. FROM hence, notwithſtanding, it is Concluded, that the Axes of the Sun, the Earth, and the Planets are Leſs than the Diameters, which are Perpendicular to them, and conſequently, that their Figures are not Spherical, but Spheroeidical; it is farther ſaid, that this Proceeds from the Revolution of their Bodies about their Axes, by which the Matter of them is made to Recede from the Poles and Aſcend to the Æquator; that in Particular, the Earth is Higher in the Latter Place than in the Former, by $31\frac{7}{12}$ Miles, and that, if it were not Higher, there wou'd be an Inundation of all the Parts and Regions under the Æquator, by an Aſcent of the Water upon them, in it's Retiring from the Poles; that the Slowneſs of the Pendulum under the Æquator Evinces this, for that proves a Defect of Gravity, and by how much Lighter the Matter of the Earth is, by ſo much Greater ought to be it's Height, that it may ſupport, by it's Weight, the Matter under the Poles, in an Æquilibrium; that the Figure therefore of the Earth's Shadow, Determin'd by the Eclipſes of the Moon, will not be exactly Circular, but it's Diameter from Eaſt to Weſt will be Greater than that from North to South, by an Exceſs of about 55″, and the Greateſt Parallax of the Moon in Longitude will be ſomething Greater than it's Greateſt Parallax in Latitude, and the Greateſt Semidiameter of the Earth will be 19767630 *Paris* Feet, the Leaſt 19609820, and the Middle 19688725 nearly; and to juſtify this Doctrine, it is farther alledg'd, that all Aſtronomers agree in their Obſervations, that the Diameter of *Jupiter* is Shorter betwixt the Poles than from Eaſt to Weſt.

See §. 16.

BUT FIRST, That the Axes of the Sun, the Earth, and the Planets are not prov'd to be Shorter than the Diameters Perpendicular to them, by the Preceding Demonſtrations, we have already ſhewn.

SECOND, To Evidence this to be Matter of Fact, there are only Two Inſtances pretended to, that of the *Earth* and of *Jupiter*; Granting which, is it neceſſary that *Mercury*, *Venus*, *Mars*, and *Saturn* ſhou'd obtain the ſame Figure, and that the *Sun* in Particular ſhou'd? If it is ſaid they all Conſiſt of the ſame Homogeneous and Similar Matter, and are exactly in the ſame Circumſtances, it is Deny'd, and wants to be Prov'd; We affirm on the Contrary, that the *Sun* conſiſts of an Expanſive Force, with ſome Contractive; and the Others of a Various Contractive, Mixt and Blended with a Various and Different Expanſive, as the Planets are more or leſs Remov'd from the *Sun*.

THIRD, But how is it Prov'd, that *Jupiter*'s Diameter is Shorter betwixt the Poles than from Eaſt to Weſt? It is ſaid by the Agreement in the Obſervations of Aſtronomers; And cou'd not the ſame Aſtronomers obſerve the ſame in the *Moon*, in *Mars*, in *Mercury*, in *Venus*, or in *Saturn*, or the *Sun*? If not, why ſhou'd the Obſervations upon *Jupiter* be a Standard for the Reſt? If they cou'd or did, why are not thoſe Obſervations here Expreſs'd? It is too Evident, that in this, as in all other Parts of the preſent Celebrated Syſtem, Nature is not Endeavour'd to be Explain'd by it, but ſubmitted and ſubjected to it; beſides which, we have given Reaſons, why the Obſervations of Aſtronomers are not too much to be Rely'd on, upon Account of the Fewneſs of Obſervers, and the Uncertainty and Difficulty of Obſerving.

The Earth in Particular not Prov'd to be Higher at the Æquator than at the Poles, from Calculation, or from it's Revolution.

FOURTH, How farther is it yet Prov'd, that the Earth's Diameter is Shorter betwixt the Poles than from Eaſt to Weſt, or in the Æquator? Namely, by a Calculation, which makes the Earth Higher in the one Caſe than the other, by 31$\frac{7}{12}$ Miles; but ſince that Calculation depends upon a Precarious Propoſition, which is not allow'd, it can be of no Service to our Conviction: Nor is that Argument more Valid, which is drawn from the Revolution of the Earth round it's own Axis, by which it's Parts are ſaid to recede from the Poles to the Æquator; becauſe, this will be Impoſſible, excepting the Earth was once a Fluid, and the ſame may be ſaid of the other Planets, but whatever our Faith, in the *Moſaick* Hiſtories, may Induce us to believe of the Earth, and may Juſtly require of us, it is not Philoſophically Evinc'd, which, in a Matter of mere Reaſoning, is always Expected; Granting yet, that the Earth and the Planets were originally in a Fluid State, it is not Demonſtrated, that they were at that Time Circulated about their Axes; And laſtly, ſuppoſing they were, a Spherical Fluid, Revolv'd upon an Axis, wou'd not produce a Spheroeid, ſince the Centrifugal Force do's not, in ſuch a Caſe, exert it ſelf in any Manner from the Poles towards the Æquator, but in Tangents to the ſeveral Revolving Circles of the Globe; and conſequently, if the Parts of the Fluid were not by their Gravity Retain'd in thoſe Circles, they wou'd not fly up towards the Æquator, but fly off in Tangents, or in ſome Lines or other Parallel to it, ſo little Reaſon is there to Amuſe us with Imaginary Inundations at the Æquator, if the Earth was not Higher there than at the Poles, Eſpecially, as the Earth is now Conſtituted, unleſs we cou'd ſuppoſe Mountains of Ice, Rolling from thence, ſhou'd overflow the Regions betwixt the Tropicks; Beſides, ſince the Æquator is the Largeſt Circle, and it's Parallels are continually Diminiſh'd, as they Approach to the Poles, and ſince their Circuits are perform'd at once, the Parts under the Æquator will be carry'd Round with a Greater Velocity, and by conſequence will obtain a Greater Centrifugal Force than the Parts, which are nearer the Poles, ſo that it do's not appear at all Reaſonable to Think, that a Leſs Centrifugal Force, nearer the Poles, ſhou'd Prevail over and Surmount a Greater, nearer the Æquator, which yet theſe Fictitious Inundations muſt Suppoſe and Preſume.

Nor from the Slowneſs of the Pendulum at the Æquator.

THE next Endeavour to Prove, that the Earth is Higher under the Æquator than under the Poles, is from the Slowneſs of the Pendulum in the Former Place, which is ſaid to Argue a Defect of Gravity, and by how much Lighter the Matter of the Earth is, by ſo much Greater ought to be it's Height, that it may ſupport, by it's Weight, the Matter under the Poles, in an Æquilibrium.

BUT, if the Slowneſs of the Pendulum ariſes from the Heat under the Æquator, as we have before ſhewn, and ſhall farther prove, this Argument is of no Force; Moreover, tho' Matter or the Pendulum and Pendulous Body, Heated by the Expanſive Force, Impreſs'd at the Æquator, may Weigh leſs than at the Poles, and therefore Deſcend Slower, that Defect of Gravity will not be owing to the one being farther Remov'd from the Center of the Earth than the other, till the foregoing Propoſition of the Lengths of the Pendulums and the Accelerating Gravities, being Reciprocally Proportional to the Diſtances from the Earth's Center, is Prov'd, but we have Evidenc'd, that there is no Demonſtration of ſuch a Propoſition; Nor yet can it be juſtly affirm'd, if the Matter is Lighter at the Æquator than at the Poles, ſuppoſing by the Expanſive Force of Heat, or any other Cauſe, (except that of Reciprocal Diſtances, which is taking for Granted, what is to be Prov'd,) that therefore by how much Lighter the Matter of the Earth is, by ſo much Greater ought to be it's Height, that it may ſupport, by it's Weight, the Matter under the Poles, in an Æquilibrium; unleſs we will allow, that the Solid Matter, under the Æquator, and the Poles, is to be conſider'd as a Fluid, and that it is Reducible to the Common Laws of Hydroſtaticks, which we have already ſufficiently Confuted; for, if Heat and Cold have a Force to produce theſe Effects of making the Pendulous Matter Lighter at the Æquator and Heavier at the Poles, there will be no Reaſon, I hope, from thence to make the Column of Solid Matter from the Surface to the

Center Longer at the Æquator than at the Poles, becauſe there is no kind of Connexion in ſuch a Reaſoning.

AND yet upon theſe Unprov'd and Uncertain Premiſes it is Concluded, that therefore the Figure of the Earth's Shadow, Determin'd by the Eclipſes of the Moon, will not be exactly Circular, but it's Diameter from Eaſt to Weſt will be Greater than that from North to South, by an Exceſs of about $55''$; Whereas this ſo Minute Obſervation is not True in Fact, for, according to Aſtronomers, that Shadow cannot be Determin'd within $12''$ at leaſt; that the Greateſt Parallax of the Moon in Longitude will be ſomething Greater than it's Greateſt Parallax in Latitude, which alſo is ſomething Minute; and that the Greateſt Semidiameter of the Earth will be 19767630 *Paris* Feet, and the Leaſt 19609320; all which is affirm'd, upon it's being ſuppos'd to be Prov'd, that the Earth is $31\frac{7}{12}$ Miles Higher at the Æquator than at the Poles, which is Determining Things again to a wonderful Minuteneſs; ſo happy is this Philoſophy in Explaining Minutiæ, which never were in Nature, as it is very Singular in Neglecting others, as the Expanſive Forces, which certainly are.

Dr. Keill's Aſtronom. Lect. 22. Pag. 321. Edit. 1.

How the Earth is prov'd to be a Spheroeid, from the Regreſſion of the Æquinoctial Points, by this Philoſophy.

Sir Iſ. Newt. Princip. Prop. 66. Corol. 20, 21, 22. Lib. 1. Prop. 21. Lib. 3. Dr. Gregory's Aſtronom. Prop. 64. Lib. 1. See Book 2. of this Philoſophy, Chapt. 5.

§. 23. AND upon this Foundation it is, that it Accounts for the Regreſſion of the Æquinoctial Points, and for the Axis of the Earth, every Annual Revolution, Changing it's Inclination to the Ecliptick twice, and twice Returning to the ſame Inclination; Becauſe it has been already prov'd, if this Philoſophy is True, that if a Body, as the Moon, Revolves about the Earth, there will be a Regreſſion of the Nodes, or a Motion of them in *Antecedentia*, and that the Inclination of it's Orbit to the Plane of the Ecliptick will be Chang'd twice in the Moon's Revolution, and will twice Recover it's Priſtine Poſition; Let therefore ſeveral Bodies be thus Mov'd round the Earth, and they will obtain like Laws with thoſe of the Moon; Let theſe ſeveral Bodies be Multiply'd in *Infinitum*, and there will be a Ring produc'd, which will be Subject to the ſame Changes of Inclination to the Plane of the Ecliptick, and to a Regreſſion of the Nodes; Let now the Globe of the Earth Swell and Extend it ſelf to this Ring; In the Flux and Reflux of the Sea, the ſaid Ring is ſuppos'd to be Fluid, and the Water to lie in an Hollow Channel, within the Surface of the Earth, but in the Preſent Solution the Ring is Imagin'd to become Solid, and to riſe above the ſame Surface, or, which is all one, the Fluid Ring is ſuppos'd to become Solid, and the Globe of the Earth to be diminiſh'd and fall below it; which is ſaid to be the Caſe of the Earth, Conſider'd as a Spheroeid, which has the Nature and Figure of a Sphere with a Circle or Ring of Redundant Matter round it, and adhering to it, and which therefore, having the ſame Axis with the Earth, will Oſcillate together with it, and the Nodes Retire in *Antecedentia*; That the Globe of the Earth will Oſcillate with the Ring is afterwards ſhewn, but take the Ring apart from ſuch Globe, and it's Greateſt Angle of Inclination will be, when the Nodes are in the Syzygiæ; From thence, as the Nodes proceed to the Quadratures, the Ring Endeavours to diminiſh it's Inclination, and Impreſſes the ſame Conatus upon the whole Globe; The Globe Retains this Motion Impreſs'd, till the Ring by a Contrary Conatus Deſtroys it, and Impreſſes a New one to a Contrary Side, by which Means, the Greateſt Motion of the Decreaſing Inclination is in the Quadratures of the Nodes, and the leaſt Angle of Inclination in the Octants after the Quadratures, becauſe the Motion Impreſs'd is ſtill Retain'd, till a Contrary Conatus alters it, which is in thoſe Octants; Then the Greateſt Motion of Reclination or Increaſing Inclination is in the Syzygiæ, and the Greateſt Angle of Inclination in the Octants following, for the ſame Reaſon; And the Caſe is the ſame of a Globe, which has no Ring, which is ſomething Higher at the Æquator than the Poles, or which Conſiſts of ſomething a Denſer Matter; for that Exceſs of Matter at the Æquator ſupplies the Place of a Ring, and altho', the Centripetal Force of this Globe being Increas'd, all it's Parts may be ſuppos'd to Tend downwards, in the Manner of Gravitating Parts of the Earth, yet there will be little Alteration from thence in the foregoing Reaſoning.

AND from hence it is ſaid, by the ſame Reaſon, that the Redundant Matter of the Globe, at the Æquator, cauſes, that the Nodes ſhou'd have a Regreſſion, and therefore, that ſuch a Regreſſion ſhou'd be Increas'd by an Increment of ſuch Matter, and Diminiſh'd by a Diminution of it, and Deſtroy'd by an Ablation of it, if more Matter be taken away than the Redundant, that is, if the Globe is more Depreſs'd, or Rarer at the Æquator than at the Poles, the Motion of the Nodes will be Progreſſive, or in *Conſequentia*.

ALSO, on the Contrary, from the Motion of the Nodes, we may Determine the Conſtitution and Nature of the Globe; Namely, if the Globe always Preſerves the ſame Poles, and the Motion is in *Antecedentia*, the Matter at the Æquator will be Redundant, if in *Conſequentia*, it will be Deficient; Suppoſe an uniform Globe, and made perfectly Round, to be firſt Quieſcent in Unreſiſting Spaces, and then, by ſome Oblique Force Acting upon it's Surface, to be Propell'd forwards, and to Admit of a Motion from thence, partly Circular, and partly in *Directum*; but, ſince the Globe is Indifferently Affected towards all it's Axes, and has not a Greater Propenſity to one Axis, or one Situation of the Axis, than to another, it is manifeſt, that it will never, by any Power of it's own, Change it's Axis, or the Inclination of it; Let there be now a Second or Third Oblique Impulſe Communicated to the ſame Globe, and at the ſame Part of it's Surface, as before, that is, in the Æquator of it's Motion, and the like Motion will be produc'd without any Alteration of the Axis, or it's Inclination; An Homogeneous and Perfect Globe therefore do's not Retain ſeveral Diſtinct Motions, but Compounds them all, and Reduces them to one, and, as to it ſelf, is always Revolv'd in a Simple and Uniform Motion about one Axis only, which is Invariable in it's Inclination; nor can the Centripetal Force change the Inclination of the Axis, or the Velocity of the Revolution Round it; for, if a Globe is conceiv'd to be divided into Two Hemiſpheres by any Plane, which paſſes thro' it's Center, and the Center, to which the Centripetal Force Tends, that Force will Equally urge both Hemiſpheres, and therefore will not Incline the Globe to either Side in Reſpect of it's Revolution; But now, if any Freſh Matter is heapt up, like a Mountain, in any Place betwixt the Pole and the Æquator, it will Diſturb the Motion of the Globe, and Cauſe it's Poles to Shift their Place and Wander upon it's Surface, and to Deſcribe Circles about ſuch Pole, and it's Oppoſite Point, by the Perpetual Conatus, which there is in this New Matter of Receding from the Center of it's Motion, in like Manner, as is done by the Poles of the Ecliptick about the Poles of the Æquator; if this Mountain of New and Acceſſory Matter is Situate in either of the Poles, the Nodes of the Æquator will be Progreſſive, as has been already obſerv'd, if in the Æquator, Regreſſive; if the Mountain of this Freſh Matter is plac'd on one Side of the Æquator, and another Maſs of New Matter is plac'd on the other, ſo that there is a Kind of Libration betwixt them, the Nodes will be Progreſſive or Regreſſive, as theſe Maſſes are Nearer to the Pole or the Æquator, becauſe they may be conſider'd in the Nature of one Maſs, which in the Poles will cauſe a Progreſſion of the Nodes, and in the Æquator a Regreſſion of Them.

AND this is the Sum of the preſent Doctrine concerning the Regreſſion of the Æquinoctial Points, and it's proving the Figure of the Earth to be a Spheroeid.

The foregoing Doctrine Refuted from ſeveral Arguments.

§. 24. IN Anſwer to which, we ſhall FIRST ſay, That this Philoſophy, as we have afterwards ſhewn, Book 2, has not given an Account of the Errors and Irregularities of the Moon, nor of the Preceſſion of the Nodes of it's Orbit, to which this Ring of Redundant and Elevated Earth is Compar'd, and Made Analogous.

See Chapt. 5. Book 2.

SECOND, Tho' ſeveral Diſtinct and Single Bodies, Anſwerable to the Moon, wou'd be ſubject to the ſame Laws of Revolving with it, yet United together and Compacted into one Solid Ring, it is not ſo Plain and Evident, that they wou'd; becauſe in a Solitary or Single Body, and ſo in ſeveral, they Paſs ſucceſſively thro' the Syzygiæ, Octants, and Quadratures, and every Point of their Orbit, and receive Impulſes from the Sun's Action, ſuitable to the Places, where they are; but when theſe ſeveral Diſtinct Bodies are Cemented into one Solid Ring, the Sun Acts upon Bodies, which Communicate with each other, and are at once in the Syzygiæ, Octants, and Quadratures, and all the Parts of the Orbit, in which a Solitary, or ſeveral Solitary Bodies, which do not Communicate with each other, ſucceſſively Revolve; and conſequently, the Effects of ſuch Action of the Sun muſt be Extremely Different in the Firſt Caſe, from what it is in the Laſt.

THIRD, But that which will Puzzle and Embarraſs this Analogy betwixt a Solitary or ſeveral Single Bodies, and a Solid Ring the more, is, that there is nothing, excepting the Action of the Sun, to diſturb the Revolution of the Former, but in the Latter, ſince it is ſuppos'd immediately to Encompaſs the Earth, the Sun and Moon have, each of them, their Particular Influences, and alſo very Oppoſite ones; ſeeing the Sun may be in one Syzygia of the Ring, when the Moon is in the Other, or in Different Quadratures or Octants, which muſt neceſſarily produce Impreſſions upon the Ring, not any ways Conſonant or Agreeable to what are made upon a Single, or ſeveral Single and Diſtinct Bodies.

FOURTH, We are farther to take Notice, that the Earth Revolves about the Sun, and conſequently, the Solid Ring with it, whilſt the Moon Revolves about the Earth, and therefore about the ſame Solid Ring, and that the Axis of the Earth and of the Ring is carry'd always Parallel to it ſelf in it's Annual Circuit; which likewiſe will occaſion a Material Difference betwixt this Caſe, and a Body's being only Revolv'd about the Earth and Sun, without it's being Carry'd with an Axis Parallel to it ſelf about the Sun, but in very Irregular and Enormous Motions about the Earth, as the Moon is.

FIFTH, Another Inſtance, in which the Solid Ring, and a Single or ſeveral Single Bodies Diſagree is, that the one Adheres to the Earth, whereas the other Circulates in Free and Unreſiſting Spaces Round it; For, if it is the ſame Thing, let one Body of the ſeveral be affixt to the Earth, and it will be Subject to the ſame Laws of it's Revolving, as if it perform'd it's Revolution at a certain Diſtance from it, but the whole Solid Ring is ſaid to be Subject to the ſame Laws; therefore the Earth will Revolve in the ſame Manner, if one Maſs of Matter, or a large Mountain is plac'd under the Æquator, as if a Ring of Elevated Matter, or a Circle of Mountains were Continu'd under it, which is too Groſs for this Philoſophy to Affirm.

SIXTH, But farther it is not Evident, nor is it Prov'd, that the Sun at that Immenſe Diſtance, which it has from the Earth, ſhou'd cauſe by it's Action any Particular Alteration by it's Impreſſions upon a Matter, which at the moſt, and by the higheſt Calculation in this Philoſophy, is only $31\frac{7}{12}$ Miles Elevated above the Reſt of it's Surface; Can there be much Difference in the Action of the Sun, which is above 50 Millions of Miles, and others make it 80, Remov'd from us, upon Two Portions of Matter, which are only Diſtant from each other about 31 Miles? And yet ſhall the whole Diameter of the Earth's Orbit about the Sun be conſider'd, as a Point in Reſpect of the fixt Stars, and the whole Earth it ſelf in Reſpect of it's Diſtance from the Sun? This ſhews, how Conſiderable the preſent Philoſophy makes it's own *Minutiæ*, and how fondly it Advances them above thoſe, which it Acknowledges in Nature, and which are yet much more Significant and Important.

SEVENTH, Granting, notwithſtanding, that the Sun do's obtain a Diſtinguiſhing Effect upon Portions of Matter, which are at ſo ſhort a Diſtance from each other, it cannot well be Imagin'd, that the Coheſion and firm Union of the Parts of the Earth ſhou'd not hinder any Impreſſions, which cou'd be made by way of Attraction, more upon one Part than another; at leaſt it is not likely, that they wou'd owe their Oſcillation to a ſmall Prominence or Protuberancy, and not be Determin'd from an Impreſſion upon the whole Globe; and therefore the Ring ſhou'd rather obey the Action of the Sun upon the whole Globe, which is not Pretended to produce any Oſcillation, than the Globe obey the Action of the Sun upon the Ring, which is ſuppos'd to do it.

EIGHTH, Beſides, tho' this Philoſophy ſays, that the Globe holds it ſelf Indifferently to all it's Axes, and therefore Conforms it ſelf to the Oſcillations of the Ring, yet a Weighty and Ponderous one, as Indifferent as it may be to it's Axes, will not be Roll'd any Way, which we Pleaſe, by the Application of a Feather; it is therefore to be ſhewn, that the Action of the Sun upon the Ring, in Diſtinction from the Reſt of the Globe, is any more to it. See Book 2.

NINTH, This is all Argu'd upon the Suppoſition of an Attractive Force in the Sun to draw the Earth towards it, but, if that Attractive Force ſhou'd prove to be an Expanſive one, by which the Earth is Repell'd from it, and which we have, Book 2, Endeavour'd to Evince, the Caſe will be alter'd, and this Philoſophy muſt have ſome New Contrivance to make ſuch a Force Square with it's preſent Reaſonings.

TENTH, But what is ſtill Worſe than all this, is, that the Earth, neither by what forego's, nor by what follows concerning Pendulums, is prov'd to be a Spheroeid, upon which yet the whole Argument Depends, and the Solution of the Preceſſion of the Æquinoctial Points.

Lastly, The ſaid Preceſſion may be Accounted for, by the Sun's Expanſive Force, in which the Earth continually Revolving, and being continually Repell'd by it, Moves thro' a Force, which Retards in ſome Meaſure it's Motion, by which it will, every Annual Revolution, be carry'd or forc'd, in ſome ſmall Degree, in *Antecedentia*, and conſequently, the Interſections of the Æquator with the Ecliptick will be ſo too.

The Different Lengths of Pendulums in Various Latitudes, no Proof of the Earth's being a Spheroid.

§. 25. **It** will be yet ſaid, that it may be ſufficiently Demonſtrated, that the Figure of the Earth is that of a Spheroid, from the Different Lengths of Pendulums in Various Climates and Latitudes, into which we ſhall now Particularly Inquire; in order to do which, it will be neceſſary for us to Examine and Compare the Two preceding Tables, the One made from a Calculation upon the Principles of this Philoſophy, the Other from Experiments.

See §. 17, 18.

And in the Firſt Place, in the Table of Experiments, *§.* 18, there are only Thirteen Latitudes of Places mention'd in all, which, ſhou'd the Lengths of the Pendulums, in each of them, have been Agreeable to what was found by Calculation, *§.* 17, it had given us a Preſumption, but not a Demonſtration that the Hypotheſis was True, namely, that the Lengths of Iſochronal Pendulums are Reciprocally, as the Semidiameters of the Earth, where they Oſcillate; But when of theſe Thirteen Latitudes, there are Two, namely, *London* and St. *Helen*'s, to which there is no Length of the Pendulum Aſſign'd, excepting in Groſs, that at St. *Helen*'s, the Pendulum is $1\frac{1}{2}$ Line Shorter than at *London*, obſerv'd by Dr. *Halley*; when farther there are Two more, *Paraiba* and *Lisbon*, to which alſo there is no Length of the Pendulum Aſſign'd, excepting in Groſs, that at the firſt Place it is $3\frac{2}{3}$ Lines, and at the Laſt $2\frac{1}{2}$ Lines Shorter than at *Paris*, according to the Obſervations of *Couplet*, which are Condemn'd and Corrected by Sir *Iſ. Newton* to $2\frac{5}{9}$, and $1\frac{1}{3}$ Lines; when likewiſe there are Three others, that is, *Cayenne*, *Martinico*, and *Paris*, to which Different Lengths of the Pendulum are Aſſign'd by Different Obſervers, namely, by *Richer* and *Des Hayes* at *Cayenne*, which Obſervations yet Sir *Iſaac Newton* Condemns and Corrects, by *Varin* or *Des Hayes* and *Feuellè* at *Martinico*, and by *Richer* and *Varin* or *Des Hayes* at *Paris*; when moreover there are only Two Obſervers, *Varin* and *Des Hayes*, who Agree in the Lengths of the Pendulums, and in only Three Latitudes, which are near to each other, and do not differ a Single Degree, namely, *Guadaloupe*, *Goreè*, and *Martinico*; and when laſtly there are Four Latitudes, *Portobel*, *Granada*, St. *Chriſtopher*'s, and St. *Dominick*, where there is only one Obſerver of the Lengths of the Pendulum, to wit, *Feuellè* or *Des Hayes*; If we conſider the ſmall Number of Latitudes obſerv'd, the Paucity of Obſervers, the Variety and Diſſonance in their Obſervations, it will be hard for us to Imagine, how any Theory or Hypotheſis can be juſtify'd from hence, and eſpecially how the Diameters of the Earth ſhou'd be aſcertain'd from ſuch Obſervations of the Lengths of the Pendulums in Different Latitudes; ſince, at the moſt, there are only Six Latitudes of the whole Number, the Lengths of whoſe Pendulums are Unconteſted, *Portobel* Obſerv'd by *Feuellè*; *Granada*, by *Des Hayes*; *Guadaloupe*, by *Varin* and *Des Hayes*; *Goreè*, by the ſame; St. *Chriſtopher*'s and St. *Dominick*, by *Des Hayes*; and of theſe Six, Four of them have only one Obſerver, which, if others were to try the ſame Experiments apart, it may be Reaſonably thought wou'd Diſagree as much as the Former.

Besides which, let us ſuppoſe theſe Obſervations True and Exact, even thoſe, which Diſagree, the Lengths of the Pendulums Gradually Increaſe, as they are carry'd from the Æquator to the Poles, in the Table form'd from Calculation; whereas in the Succeeding one, made from Experiments, the Length of the Pendulum at *Cayenne*, according to *Richer*, *Des Hayes*, and Sir *Iſ. Newton*, which is only $4^{\circ}.55'$ Latitude, is Greater than, according to *Feuellè*, at *Portobel*, which is $9^{\circ}.33'$ Latitude, and Equal, according to *Des Hayes*, to the Length of it at *Granada*, which is $12^{\circ}.6'$ Latitude, but Greater according to *Richer* and Sir *Iſ. Newton*, alſo Equal, according to *Varin* and *Des Hayes*, to the Length of it at *Guadaloupe*, which is 14° Latitude, but Greater according to *Richer* and Sir *Iſ. Newton*, again almoſt Equal, according to *Varin* and *Des Hayes*, to the Length of it at *Goreè*, which is $14^{\circ}.40'$ Latitude, but Greater according to *Richer* and Sir *Iſ. Newton*, Farther, exactly Equal, according to *Varin* and *Des Hayes*, to the Length of it at *Martinico*, which is $14^{\circ}.44'$ Latitude, but Greater according to *Richer*, Sir *Iſ. Newton*, and *Feuellè*; And yet on the Contrary, if theſe Experiments any way Correſponded with the abovesaid Calculations, the Length of the Pendulum at

Cayenne ought to be Leſs than at *Portobel*, *Granada*, *Guadaloupe*, *Goreè*, and *Martinico*, tho' they unanimouſly Agree to make it Equal or Greater: Thus likewiſe the Length of the Pendulum ſhou'd be Leſs at *Granada* than *Guadaloupe*, and at *Guadaloupe* than *Martinico*, albeit *Varin* and *Des Hayes* make them Equal; Nay, which is ſtill more Extraordinary, *Richer*, and Sir *Iſ. Newton*'s Correction upon him, makes the Length of the Pendulum Greater at *Cayenne*, which is only 4°. 55′ Latitude, than at St. *Chriſtopher*'s, which is 17°. 19′ Latitude, or at St. *Dominick*, which is 19°. 48′ Latitude.

Moreover, According to the Table of Calculations, the Greateſt Difference betwixt the Length of the Pendulum at the Æquator, and at the Poles, namely, betwixt 3 . 7,468, and 3 . 9,387 Feet and Lines, is 1,919 Line, that is, not quite 2 Lines, but as thoſe Calculations were made upon the Suppoſition of the Earth's being uniformly Denſe, if it's Matter is Denſer nearer the Center than at the Surface, the Difference of the Pendulums will be ſomething Greater, and therefore, in the preſent Caſe, let that Difference be a little more than 2 Lines.

But *Couplet* at *Paraiba*, which is 6°, 38′ Latitude, obſerv'd the Length of the Pendulum to be $3\frac{2}{3}$ Lines leſs than at *Paris*, which is 48°. 45′ Latitude, and which Sir *Iſ. Newton*, upon a Correction of this Groſs Obſervation, as he Eſteems it, makes $2\frac{5}{9}$ Lines leſs, Either of which will be a Confeſſion, that the Difference of the Lengths of the Pendulums is Greater, or about as Great, at the Diſtance of 42°. 7′, as of 90°, which is Impoſſible; Eſpecially, when according to the Table of Calculations, the Difference betwixt the Lengths of the Pendulums at 5° Latitude and 48°, which comes the neareſt to the preſent Caſe, namely, the Difference betwixt 3 . 7,482 Feet and Lines, and 3 . 8,528, is only 1,046, that is, ſomething more than a Line, and not $1\frac{1}{4}$ of a Line, allowing for a Greater Difference upon Account of the Earth's being Denſer at the Center than at the Surface.

At *Liſbon*, which is 40° Latitude, the ſame *Couplet* found the Length of the Pendulum $2\frac{1}{2}$ Lines leſs than at *Paris*, which is 48°. 45′ Latitude, and according to Sir *Iſ. Newton*'s Correction it is $1\frac{1}{3}$, but the Difference betwixt 40° and 48°. 45′ is 8°. 45′, So that here is a Difference of the Lengths of the Pendulums, within $\frac{2}{3}$ of a Line, almoſt Equal to what belongs to a Difference of 90° Latitude, which is Impoſſible; Eſpecially, when we farther conſider, that the Difference of the Length of the Pendulum, which belongs to 40° Latitude, which is 3 . 8,261 Feet and Lines, and of that, which belongs to 48° Latitude, which is 3 . 8,528 Feet and Lines, is no more than 0,267, or not much above $\frac{1}{4}$ of a Line in the Table of Calculations.

Dr. *Halley* obſerv'd at St. *Helen*'s, which is 15° Latitude, that the Length of the Pendulum was $1\frac{1}{2}$ Line leſs than at *London*, which is 51°. 30′ Latitude, ſo that, according to this Experiment, the Difference of only 36°. 30′ Latitude will require almoſt as Great a Difference in the Lengths of the Pendulums, as the Difference of 90° Latitude, which is again Impoſſible; Eſpecially, when we farther conſider, that the Difference of the Length of the Pendulum, which is over againſt 15° Latitude in the Table of Calculations, and of that, which ſtands oppoſite to 50° Latitude in the ſame Table, Namely, of 3 . 7,596 and 3 . 8,594 Feet and Lines, is no more than ,998 of a Line, that is, not one entire Line.

According to *Des Hayes*, the Length of the Pendulum at *Guadaloupe* and *Martinico*, which are 14° and 14°. 44′ Latitude, is $\frac{1}{2}$ a Line leſs than at St. *Dominick*, which is 19°. 48′ Latitude, which is the Difference of $\frac{1}{2}$ a Line for a Difference of a little more than 5° Latitude, and yet there is but about 2 Lines Difference for a Difference of 90° Latitude; and in the Table of Calculations, the Length of the Pendulum at 15° is 3 . 7,596, and at 20°, 3 . 7,692, from whence the Difference of the Lengths, for a Difference of 5°, will be only ,096 of a Line, which will fall very much ſhort of ,500 = $\frac{1}{2}$ of a Line, and cannot be repair'd by ſuppoſing the Earth Denſer at the Center.

Again, according to *Richer*, the Length of the Pendulum at *Cayenne*, which is 4°. 55′ Latitude, is $1\frac{1}{4}$ Line leſs than at *Paris*, which is 48°. 45′ Latitude, but according to *Des Hayes* $2\frac{1}{18}$, and by the Table of Calculations the Length of the Pendulum at 5° Latitude is 3 . 7,482, and at 48° Latitude 3 . 8,528, from whence the Difference will be 1,046, which is much Leſs than either $1\frac{1}{4} = 1{,}250$, according to *Richer*, or than $2\frac{1}{18}$ according to *Des Hayes*; and neither of 'em bear any Proportion to the Difference of the Pendulum's Lengths for the Difference of 90° Latitude; ſince the Difference, in the Preſent Caſe, is 43°.50′ Latitude, to which *Des Hayes* aſſigns a Difference of the Length of the Pendulum almoſt Equal to that, which belongs to a Difference of 90°, *Richer* is ſomething too High, and both Diſagree very much with what the Calculation makes it.

And by the ſame Method of Examining we ſhall find, that the few Remaining Experiments bear no Analogy, in the Differences of the Lengths of the Pendulums at any Intermediate Latitudes, with that ſuppos'd Difference, which is betwixt them under the Æquator and Poles; nor yet, that they in any Meaſure Correſpond with the Differences of the Lengths, aſcertain'd in the Table of Calculations; which cannot but be a full Confutation of the preſent Theory of Pendulums, and the Computed Lengths of them, in Various Latitudes, deriv'd from it.

From whence the Different Lengths of Pendulums in Various Latitudes and Climates, as well as in the ſame do Really ariſe.

§. 26. But to ſtrike at the Foundation of all this Reaſoning we farther affirm, that the Shortneſs of Synchronal Pendulums at the Æquator, and the Increaſe of their Lengths towards the Poles, do's not ariſe from the Elevation of the Earth in the one Place, and the Depreſſion of it towards the others, but from the Various Temperature of the Air and Climate, and particularly with Relation to the Heat and Cold Experienc'd in them, which from Different Cauſes may be Different in the the ſame Climates or Regions, and nearly the ſame in Different ones; ſince we do not find all Countries Equally Hot or Cold, which are in the ſame Latitude, nor Differently Hot or Cold, which are in Different ones; And from hence there may be ſome Account given of the Variety and Diſagreement of Obſervations in the ſame Latitudes, as alſo of the Length of the Pendulum not being Increas'd or Diminiſh'd in Proportion to it's Removal from the Æquator or Approach to it.

Thus at *Cayenne*, the Reaſon, why the Length of the Pendulum was leſs according to *Des Hayes*'s Obſervations, by ſomething more than $\frac{1}{2}$ a Line, than according to *Richer*'s Obſervations, might probably be, that the Experiments of the Former were made in an Hotter or Dryer Seaſon or Air, and thoſe of the Latter in a Colder or Moiſter; for it is known, that betwixt the Tropicks their Rain is their Winter.

The Length of the Pendulum at *Paraiba*, according to *Couplet*, was $3\frac{2}{3}$ Lines leſs than at *Paris*, becauſe the Temperature of the Air is much Hotter in the one Place than the other.

Feuellè obſerv'd the Length of the Pendulum to be leſs at *Portobel*, which is 9°.33′ Latitude, than *Richer* or *Des Hayes* did at *Cayenne*, which is only 4°.55′ Latitude, becauſe the Heats were Greater, it is likely, at *Portobel* than at *Cayenne*, when thoſe Obſervations were made, or the Weather and Seaſon Dryer at the firſt Place, and Moiſter at the Laſt.

In like Manner, the Length of the Pendulum, according to *Varin* and *Des Hayes*, was much the ſame at *Granada*, *Guadaloupe*, *Goreè*, and *Martinico*, whoſe Latitudes are 12°.6′, 14°.0′, 14°.40′, 14°.44′, becauſe we may juſtly Imagine, the Heats of thoſe Places are nearly the ſame, or the Seaſons of the Year, in which the Obſervations were made, were ſo far Different, as to Compenſate for the Difference of the Climates, and Render the Temperature of the Air very much Equal; and *Feuellè*'s Pendulum at *Martinico* was Shorter than *Varin*'s and *Des Hayes*'s, becauſe he obſerv'd in an Hotter or Dryer Seaſon.

Dr. *Halley*'s Pendulum at St. *Helen*'s was Shorter than at *London*, becauſe the Heats were more Extraordinary at 15° Latitude than at 51°.30′.

Des Hayes's was Shorter at St. *Chriſtopher*'s than at St. *Dominick*'s, *Couplet*'s at *Lisbon*, and *Des Hayes*'s at *Cayenne*, than at *Paris*, for the ſame Reaſon.

And laſtly, *Varin*'s and *Des Hayes*'s was Shorter at *Paris* than *Richer*'s by $\frac{2}{45}$ of a Line, becauſe the Firſt obſerv'd in an Hotter or Dryer Seaſon, and the Laſt in a Colder and Moiſter.

This Account therefore depends upon the Suppoſition, that the Lengths of the Pendulum are to be Diminiſh'd in an Hotter or Dryer Climate and Temperature of the Air, and to be Increas'd in a Colder or Moiſter. But it is Matter of Fact and Experiment, and ſo acknowledg'd by this Philoſophy, that Pendulums move Slower in the ſame Climate, in Summer than in Winter, in an Hotter than a Colder *Craſis* or Temperature of the Air; and, as Dryneſs ariſes from Heat and Moiſture from

Cold, there is the ſame Reaſon to affirm, that in ſome Degree, a Pendulum moves Slower in a Dry, if ſomething Hot, than in a Moiſt Seaſon, if Cold, and we have Endeavour'd from the Expanſive and Contractive Forces to give a Solution of this Phænomenon; For it is Plain, that an Expanſive Force makes a Pendulous Body Lighter, and to Deſcend Slower, and a Contractive Heavier, and to Deſcend Quicker; It is therefore Manifeſt, that if a Pendulum moves Slower in an Hotter or Dryer *Craſis* or Temperature of the Air than in a Colder or Moiſter, to make it Oſcillate in the ſame Time, that is, in the Second of a Minute for Inſtance, the Pendulum muſt be ſhorten'd in the firſt Caſe, and lengthen'd in the Laſt; becauſe, if the Force of the Pendulous Body is Diminiſh'd, ſo that it moves Slower, it muſt be carry'd Nearer to the Center of Suſpenſion, that it may Deſcribe a Similar Arc of a leſs Circle in it's Oſcillation in the ſame Time, that a Greater Force Deſcribes a Similar one of a Larger; and on the Contrary, if the Force of the Pendulous Body is Increas'd, ſo that it moves Faſter, it muſt be carry'd to a farther Diſtance from the Center of Suſpenſion, that it may Deſcribe a Similar Arc of a larger Circle in the ſame Time, that a Leſſer Force Deſcribes a Similar Arc of a Leſs.

Besides which, ſince the Oſcillations of a Pendulum, which we have before ſhewn, Proceed from the Conteſt, which there is betwixt the Expanſive Force of the Pendulous Body and the Contractive Force of the Center of Suſpenſion; As the Expanſive Force of the Pendulous Body, that is, in the Preſent Caſe, it's Gravitating, is Diminiſh'd by the Expanſive of Heat, it muſt approach Nearer to the Contractive Force of the Center of Suſpenſion or Rotation, and as the ſame Expanſive Force of the Pendulous Body, that is, it's Gravitating, is Increas'd, it muſt Retire farther from the Contractive Force of the Center of Suſpenſion, to Produce the ſame Effect, that is, to Meaſure the ſame Time; becauſe the Nearer any Force is to a Contrary, the more it Partakes of and Communicates with that Force, and is Govern'd by it, and the farther it is from it, it is the leſs Affected with it, whilſt both Exert their Effects in the ſame Time; Thus in the Common Deſcription of a Circle, the Expanſive Force is Slower, the Nearer it is to the Center, which is Quieſcent, and Quicker the more it is Remov'd from it, in Order to produce Two Concentrical Circles, whoſe Times of Deſcription are notwithſtanding the ſame.

The Objections againſt the preceding Explanation Anſwer'd.

See §. 18.

§. 27. But it is objected to this Explanation of the Lengthening and Shortening of Pendulums from Heat and Cold, that, from the Obſervations of *Picart*, the Iron-Rod of the Pendulum, which in Froſty-Weather was one Foot Long, being heated at the Fire, was only one Foot and $\frac{1}{4}$ of a Line, and that, from the Obſervations of *De la Hire*, the Iron-Rod, which in the like Froſty-Weather was Six Feet Long, in the Summer-Heats was only Six Feet and $\frac{2}{3}$ of a Line, that indeed the Summer's Sun do's make Metals exceeding Warm, which are Expos'd to it, but that the Rod of a Pendulum in a Clock is never Expos'd to the Heat of the Summer's Sun, and never has an Heat Equal to that of the External Parts of an Human Body, becauſe, the Pendulum will always be perceiv'd Cold to them; and therefore the Rod of a Pendulum, which is Three Feet Long, will be ſomething Longer in Summer-Time than in Winter, by an Exceſs of little more than $\frac{1}{4}$ of a Line, and conſequently can be ſhorten'd no more, which cannot poſſibly give an Account, why the Pendulum ſhou'd be ſhorten'd at the Æquator, 2 Lines or more; from whence it is Infer'd, that the whole Difference of the Length of Pendulums, which in Various Climates are Iſochronal, cannot be aſcrib'd to the Different Heat of thoſe Climates, nor yet to the Errors of the Obſervers, which are Small and Inconſiderable; and in this they all Agree, that the Iſochronal Pendulums are Shorter under the Æquator, than at the Royal Obſervatory at *Paris*, by a Difference of about 2 Lines.

In Anſwer to which we ſay, that, becauſe the Length of the Pendulum is only Increas'd about $\frac{1}{4}$ of a Line by Heat, and therefore can be ſhorten'd no more upon that Account, is no Argument, that it may not be ſtill ſhorten'd upon the Account of it's Slowneſs, and that ſuch Slowneſs is not owing to Heat; Since the Expanſive Force of Heat Diminiſhes the Contractive, or the Weight, of the Pendulum, and what is Lighter Deſcends Slower; The Obſervations therefore of *Picart* and *De la Hire* do not Overthrow what we have ſaid, but Confirm it, and Evince, that the Pendulum is to be ſhorten'd, by Reaſon of Heat's Swelling and Increaſing the Length of it by it's Expanſive, and we add, that it is likewiſe to be ſhorten'd, becauſe Heat by it's Expanſive Increaſes the Slowneſs of it.

'Tis alſo acknowledg'd, that Metals do admit of a Great Degree of Heat or Warmth from the Rays of the Sun in Summer, and tho' the Pendulum is not Expos'd to the open Violence of it, it partakes of the Effects, which are Communicated to the whole Air, by which it becomes of a Sultry Temper and Diſpoſition, even in Places, which are not Obnoxious to the Impreſſions of the Direct Rays from the Solar Subſtance; and albeit the Heat of the Pendulum may not Exceed the Heat of the External Parts of an Human Body, yet conſidering, that the Heat of thoſe External Parts is mightly Increas'd in Summer, in Reſpect of what they have in Winter, the Heat of the Pendulum will receive a Proportionable Augmentation, compar'd with what it has in Froſty Weather, and ſuch a one as may be ſufficient to produce it's apparent Slowneſs.

As to the Errors of Obſervers, we do not Charge any upon them, but have Endeavour'd to ſhew, that the Variety of Obſervations, even in the ſame Region and Climate, may be juſtly Accounted for in the Way we have Propos'd; On the Contrary, *Couplet* is made to be a Groſs Obſerver, and other Obſervations are Eſteem'd Erroneous by this Philoſophy, becauſe they do not ſo exactly Square and Agree with it's Suppoſitions, and the Calculations upon them; which is a very unfair Method of Judging and Determining concerning the Truth of Experiments, and is really Endeavouring to make Nature ſubmit to our Speculations and Fancies, whereas our Reaſonings and Imaginations about it ought to be Accommodate and Conformable to Nature; but this is not the only Inſtance of this Way of Proceeding in the Preſent Philoſophy, I have ſhewn in my *Principles of Natural Philoſophy*, that it takes the ſame Courſe in Accounting for the Propagation of Sounds, and that it has done the like in Aſtronomy I have alſo Evinc'd, which was the chief Reaſon, or elſe I am Miſinform'd, of the Complaints of Mr. *Flamſteed*, and his Burning the Copies of his Aſtronomical Obſervations, which were Printed under other Men's Directions, becauſe they had Alter'd and Mangled them, and made them Different from what he obſerv'd, on Purpoſe to Confirm the New Notions Introduc'd in the Phyſical Aſtronomy.

For in the Preſent Caſe, why ſhou'd one Obſerver be Prefer'd to Another, why ſhou'd *Couplet* be a Groſs one, and *Varin* and *Des Hayes* more Accurate? Is there any Thing alledg'd in the Genius of the Men, or in the Pendulums which they us'd, which ſhou'd make the one more to be Depended upon, than the other? *Couplet*'s Obſervation is Corrected; but how? Namely, by ſuppoſing the Principles of this Philoſophy True, upon which it Calculates, whereas thoſe Principles ought to be prov'd True by thoſe Experiments it Preſumes to Correct; Either we muſt fix the Certainty of Experiments, or elſe entirely Diſcard them, and if thoſe Experiments ſeem to Claſh and Interfere with each other, we muſt find out Principles, which will Anſwer thoſe ſeeming Contradictions, or Reject the Whole as a Fallacious Buſineſs; but to take ſome Experiments, which Agree with our Hypotheſes, and to Slight and Diſregard, or Tamper with others, which do not, is a Cunning and Artificial Procedure, but not an Honeſt and a True one, and is more ſuitable to the Character of a Sophiſter and Jugler in Reaſon, than of a Philoſopher.

As to the Agreement of Obſervers in this, that Iſochronal Pendulums are Shorter under the Æquator than at the Royal Obſervatory at *Paris*, there is an Evident Reaſon for it, if Heat and Cold are the Grand and Principal Regulators of them, as we have hitherto Endeavour'd to Shew and to Demonſtrate.

Concluſion upon this Whole Doctrine.

§. 28. I Shall Conclude this Doctrine of Pendulums with Obſerving, that in my *Principles of Natural Philoſophy*, which, upon the Publiſhing of them, I immediately ſent to Sir *Iſ. Newton*, Chapt. 5. §. 16. I had Affirm'd, that the Reaſon, why Pendulums did not Oſcillate Equably in Different Climates, was the Difference of the Medium, in which the Oſcillations were made, what that Difference of the Medium was, I had no occaſion then to Conſider; I added, Referring to Sir *Iſaac Newton*'s Princip. Prop. 20. Lib. 3. and Dr. *Gregory*'s Aſtronom. Prop. 52. Lib. 3. That we cou'd not Reaſonably Attribute this Inequality of the Motion of the Pendulum to an Alteration in the Figure of the Earth in Various Parts of it, however Ingenious ſome Calculations might be in order to Prove it; Upon a Second Edition of his Principles, this Point was Labour'd with much more Accuracy than in the Former, but whether he has Prov'd what I there Deny'd, I now leave Others to Judge, and whether I had not ſome Grounds to Affirm, that it was an Ingenious Calculation only.

Dr. Keill's Intr. ad Ver. Phyſ. Lect. 16. Theorem 47, 48, &c. See Principles of Philoſ. Chap. 5. §. 6. Book 1.

The Nature of Projectiles.

As to the Doctrine of Projectiles, which follows in this Philoſophy, and that the Line Deſcrib'd by them is a Parabolick Curve, we have already taken Notice of it in our *Principles of Natural Philoſophy*, and ſhewn, that it entirely Depends upon the Suppoſition of Matter's being Similar and Homogeneous, and that it is Acted by uniform Impulſes of Gravity, neither of which Hypotheſes we Can or are Willing to Allow.

ALL that we ſhall farther ſay is, that Bodies, when Projected, perform Various and Different Figures, according to the Greater or Leſs Reſiſtance of the Medium, and the ſeveral Degrees of the Expanſive and Contractive Forces, with which they are Endu'd, as alſo according to the Proportion of the Expanſive Force, which is Communicated to them from the Projection, and of the Contractive Force of Gravitation, by which they are Impell'd to the Earth; and Caſes, diſtinctly put in Reſpect to each of theſe Forces, wou'd ſupply us with many New Theorems unknown to the Preſent Doctrine, which only conſiders one Caſe, namely, where the Matter is the ſame, and a-like, and where the Force of Gravitation is ſo too, and Acts by Continual and Invariable Percuſſions upon it, by which it is Accelerated towards the Earth's Center.

BOOK II.

CONCERNING THE
PHYSICAL ASTRONOMY.

THE PRINCIPLES of the PHILOSOPHY OF THE EXPANSIVE and CONTRACTIVE FORCES.

BOOK II.

Concerning the PHYSICAL ASTRONOMY.

CHAP. I.

Concerning the Laws of Nature and Motion.

§. 1. WE have in ſome Chapters of our Former Book Examin'd into the Principles, by which the Mechanical Powers have hitherto been Accounted for; We might now Proceed to the New Hypotheſis rais'd to Explain them, but ſince That is deriv'd from a Law of Motion, concerning the Compoſition of Forces, aſſerted in the Preſent Philoſophy, it will be Neceſſary for us to defer the Conſideration of it, till we come to Enquire into the Law it ſelf, and the Foundations and Reaſons, on which it is Eſtabliſh'd; In Order to which we ſhall conſider the Laws of Nature in the Method they are Propos'd to us, and which, together with the Opinions concerning Matter and Motion, which it Eſpouſes, and were before Conſider'd, are the Baſis of all the ſucceeding Philoſophy.

The Laws of Nature and Motion conſider'd.
Sir Iſ. Newt. Princip. Mathem. Corol. 2. Leg. Mot.

§. 2. THE Firſt Law of Nature or Motion affirm'd is, that every Body perſiſts in it's State of Motion or Reſt Uniformly in Directum, unleſs ſo far as it is oblig'd to change that State by ſome Force or other Impreſs'd upon it; Thus, it is ſaid, Projectiles continue in their Motion, unleſs ſo far as they are Retarded by the Reſiſtance of the Air, or Thrown to the Ground by the Force of Gravitation; A Globe or Cylinder, which Revolves upon it's own Axis, continues to Move, till it is made to Ceaſe, by ſome External Renitency to it; And the Large and Immenſe Bodies of the Planets and Comets preſerve their Progreſſive and Circular Motions to an unlimited Time, becauſe their Spaces have little or a very Inſenſible Reſiſtance in them.

Firſt Law of Nature or Motion explain'd.
Mr. Whiſton Phyſico-Math. Prælect. 5. Art. 1.
Dr. Keill's Intr. ad Phyſ. Lect. 11. Lex. 1.
Sir Iſ. Newt. Princip. Math. Lex. 1.

§. 3. WE ſhall not conſider the Reaſon, at preſent, of a Stone Falling to the Ground, or a Body Revolving upon it's Axis, or the Planets and Comets Preſerving their ſtated Periods, or whether Comets are Mov'd at all in a Circuit, or not; what we ſhall obſerve is, that for a Proof of the Law of Nature, it is ſuppos'd, that Nothing hinders a Projectile from Moving on for ever, excepting the Air, and it's own Proper Gravitation; That Nothing reduces a Body Revolv'd round it's Axis to a Quieſcence, excepting the Air, *&c*; That Nothing obſtructs the Circumgyration of the

The Inſtances alledg'd improper to Evince this firſt Law of Nature or Motion.

the Planets, unleſs an Infinitely ſmall Reſiſting Medium, and therefore they may move on to Innumerable Ages; And laſtly, That Planets and Comets are carry'd Round in a Circular and Progreſſive Motion, that is, in a Motion which is Compounded of a Direct, and a Centripetal; All which are Problems in Philoſophy, which require an Accurate, and Juſt Solution, and therefore are Improperly brought to juſtify the Firſt Law of Nature, before it is more certain than from an Hypotheſis only, that Motion is Stopt or Continued from theſe Cauſes; Since, for all that is yet Prov'd, Bodies may Ceaſe to Move after they are put into Motion by their own Innate and Contractive Forces, according to what has been before Explain'd, and others may continue to Move longer than in Proportion to the Force Impreſs'd by their own Proper Expanſive.

Whether this Law of Nature or Motion can be juſtify'd from a True Idea of Matter and Motion.

§. 4. SINCE therefore theſe Inſtances of Fact can ſignify nothing to the Aſcertaining the preſent Law of Nature or Motion, till they are Evidenc'd to proceed from the Cauſes aſſign'd to them, which cannot be done, in Reſpect of the Motion of Projectiles in particular and of the Planets, excepting upon the Suppoſition of this Law of Nature, it is manifeſt there is no Proof of it to be expected from them; The next Thing we ſhall conſequently inquire into, is, whether ſuch a Law of Nature or Motion can be deriv'd from a True Idea of Matter and Motion, or even from that, which this Philoſophy Propoſes.

If there are Innate Expanſive and Contractive Forces in Matter this Law will not be True.

§. 5. THAT it cannot from a True Conception of Matter, as it really Exiſts, is Evident, ſince we find ſome Matter to Gravitate, as Lead, and other to Aſcend, as Fire, whereas this Law ſuppoſes a perfect Inertia in Matter, conſider'd in it ſelf, without any other Force belonging to it; for if Matter, as was juſt now mention'd, has an Innate Force of Gravitation and Contraction, or of Aſcenſion and Expanſion, tho' a Motion is Impreſs'd upon it, it will not be neceſſary, that it ſhou'd Continue in that Motion, till ſome External Force puts a Stop to it, ſince it's own Innate Force of Gravitation may give a Check, or it's Expanſive, as in Flame, an Addition to it.

If there is a Perfect Inertia in Matter, the Leaſt Force Impreſs'd will be Equally capable of Moving the Greateſt, or the Minuteſt Body.

§. 6. THE Idea of Matter, which this Philoſophy aſſerts, is, that it is Endu'd with a Perfect Inertia, and therefore, if it is in Reſt or in Motion, it muſt continue ſo, unleſs we ſuppoſe it can Move it ſelf, when at Reſt, or Stop it ſelf, when in Motion; But if there is an Abſolute Inertia in Matter, ſo that it has no Force or Activity of it's own, it will be conſequent, that the Leaſt Impreſs'd Force will be capable of Moving the Greateſt Body Equally with the moſt Minute; for whilſt Matter is Nothing elſe but a Maſs of Something, which neither Acts nor Reſiſts, if we take a Greater or a Leſſer Portion of it, it will be the ſame; And for a Parallel Reaſon, that 3 Nothings are Equal to 5 or 100, ſince a Sum or Aggregate of 3 Portions of Inaction in Reſpect of Motion, will be all one with 5 or 100.

Motion and Reſt may as well be affirm'd of an Abſtracted Idea, as of Matter, which has an Entire Inertia.

§. 7. THE Truth is, as we have before obſerv'd, Matter without any kind of Force, whether of Activity or Reſiſtance, that is, when we make it no more than an Extended and Impenetrable Subſtance, is not any thing elſe than an Abſtracted Idea, it is a Notion of the Mind, and we may as well affirm a Mathematical Surface, or Solid to perſiſt in it's State of Motion or Reſt, as Matter to do it, whilſt we conſider Nothing in Matter but Space, and without any kind of Force belonging to it; and it will be eaſy for us to band a Thought about of our own Forming, as we pleaſe, tho' it will be ſcarcely a Queſtion, whether an Abſtracted Idea, any more than Space which is one, is capable of any Real Motion at all, becauſe it certainly is not.

The Vis Inertiæ, *as defin'd by* Sir Iſ. New*ton, ſeems to be little elſe than a Contradiction.*
Sir Iſ. Newt. Princip. Math. Defin. 3.

§. 8. IF the foregoing Sections are True, it will be farther Difficult to account for another Property, which is aſſerted concerning the Inertia, that it is an Innate Force, by which Matter is very hardly, and with Reluctance, made to change it's State of Reſt into Motion, or the Contrary, and indeed ſo Difficult, as will require a Sagacity capable to Reconcile Contradictions; for Matter, by the foregoing Property of it's Inertia, will continue in the Motion or Reſt Impreſs'd upon it, becauſe it has no Force of it's own, but in this Second Property it will be hard to put it out of the State in which it is, becauſe it has a Force of it's own; that theſe Philoſophers may therefore be conſiſtent with themſelves, we muſt tell them, that their Notion of Matter is well Adapted to ſolve both, being an Abſtracted one, which may, on that Account, be with or without Force, according to the Humour they are in, of making an Inſignificant and Trifling, or a very Weighty and Important Buſineſs of it.

§. 9. To Conclude, all that can be ſaid for the Inertia of Matter is, That it is Repugnant to our Notions of it, that Lead ſhou'd Move it ſelf, when in Reſt, or that Fire ſhou'd Determine it ſelf to Reſt, when in Motion, but this does not Evince, that Matter may not have ſome kind of Active Principle in it, becauſe it is ſuppos'd to have none in both theſe Caſes, but the Contrary; for therefore Lead will Determine it ſelf to Reſt, when put into Motion, for this Reaſon only, that it was Difficult to put it into Motion, and Fire wou'd Determine it ſelf to Motion, tho' an External Force was us'd to Quench it, the Firſt from it's Innate Contractive Force, and the Laſt from it's Innate Expanſive. That is, the Contractive Force is Reluctant to the Expanſive, and the Expanſive to the Contractive, but this is not an Inertia, but Force or Action.

The contractive Force has a Reluctance to the Expanſive, and the Expanſive to the Contractive, which is not an Inertia, but Reſiſtance and Action.

§. 10. A Second Law of Nature affirm'd is, that all Motion in it ſelf is Rectilinear, or directed from one Point to another in a ſtrait Line, which is ſuppos'd to follow from the Nature of Motion, ſince it cannot be conceiv'd without ſome Determination from the Point, from which it Commences, and according to the Former Law it muſt Perſevere in that Determination, till it is Chang'd by ſome Foreign Impreſſion; from whence it follows, that where any Body is Mov'd in a Curve, it is made to do it from the Direction and Influence of an External Force, and where ſuch External Force Ceaſes, it will Relinquiſh the Curve, and Proceed again in a ſtrait Line, which is a Tangent to it, at the Point of the External Force's Ceaſing; Thus a Stone whirl'd Round in a Sling deſcribes a Circle, whereas, when it is once quit of it, it flies off in a Tangent.

The Second Law of Nature or Motion Explain'd.

Mr. Whiſton. Prælect. Phyſ. Math. 5. Art. 2. Dr. Keill's Introduct. Sir Iſ. Newt. Princip.

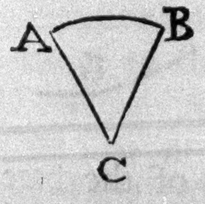
§. 11. That Motion of what kind ſoever muſt have ſome Determination or other is manifeſt, but that a Rectilinear is more Natural to it than a Circular, we deny, ſince it is only offer'd to be Prov'd by the preceding Law of Bodies Perſevering in that Form or Condition of Motion, which is firſt Impreſs'd; Since therefore, that Law is either Uncertain or Falſe, it will be Impoſſible for us with any Safety to depend upon what is Concluded from it; The Motion of Fire Acts in all Kind of Directions, as is Evident from the Undulations of the Flame of it; Water Spilt upon the Ground makes a Thouſand Irregular Forms, *&c.* and ſo it is in Hard Bodies Dropt upon it, which acquire Various Determinations, according to their Different Nature and Action.

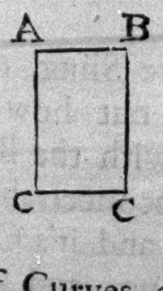
A Rectilinear Motion not neceſſary, or the moſt Natural to Bodies.

§. 12. But that which is more Unfortunate to this Philoſophy is, that a Motion from a Perſeverance of it in one and the ſame Direction, in which it firſt begins, is no more Prov'd to be naturally Rectilinear than Circular, if there may be a Circular Determination, as well as a Rectilinear; and that there in Fact is, is Evident from the very Generation of a Circle, which does not nor can conſiſt of an Infinite Number of ſtrait Lines, as is generally Imagin'd, but the firſt Progreſs it makes is in a Curve; ſince Two Points in a Circle, which are Equidiſtant from a Third, muſt neceſſarily lie in a Curve, according to *Euclid*, and if they approach Infinitely near to each other, will make an Infinitely Small Convexity; But in Deſcribing a Circle there is nothing more to be obſerv'd than the Flux of the Point of the moveable Extremity of the Radius, as in Deſcribing a Right Line the ſame Point is to be obſerv'd, whilſt the whole Radius is carry'd Parallel to it ſelf, which Motions are Expreſs'd in the Figure annext; which if Impartially conſider'd, we ſhall find the Curve *AB* to be as Natural a Determination, where *C* is fixt, and *A* is mov'd, as the Right Line *AB*, where *A* and *C* are both Equably Mov'd. Nor, in this Deſcription, is *AB* in *ACB* any more Retain'd in a Curve, and kept from performing a Strait Line, by a Force in *C*, than *AB* in *ABCC* is preſerv'd in a Direct Line, and kept from performing a Curve, by a Force in *CC*; that is, it is not more Natural, that *C* ſhou'd be moved at the ſame Time that *A* is, than that *C* ſhou'd be fixt whilſt *A* is mov'd, or, which is all one, a Parallelogram is not a more Natural Figure than a Circle.

A Rectilinear not more Natural than a Circular Motion.

Elem. 3. Prop. 2.





§. 13. It is very plain in Mathematicks, that the Circle, the Parabola, Hyperbola, Ellipſis, the Cycloïs, and the whole Order of Curves, are as much deſcrib'd by Determinations peculiar and diſtinct to themſelves, as a Strait Line is, and if we begin in any one of thoſe Determinations, we

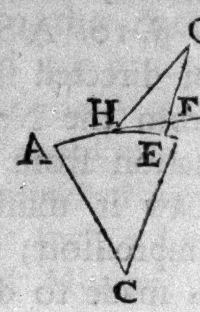
This Rectilinear Motion is aſſum'd as the moſt Natural in Order to Eſtabliſh the

ProjectileForce, whereas the Projectile Force ought to be prov'd to Eſtabliſh the Naturalneſs of the Rectilinear Motion.

always end with it; why therefore a Rectilinear Determination ſhou'd be more Proper to Motion than any other will not be eaſily Comprehended, unleſs by entering into the Deſign of Affirming it, which is to Introduce the Neceſſity of a Projectile and a Gravitating Force in the Elliptick Orbits, which are deſcrib'd by the Heavenly Bodies according to this Philoſophy; That Projectile and Gravitating Force therefore is to be prov'd to Confirm this Law, whereas this Law is on the Contrary Eſtabliſh'd to prove ſuch a Gravitating and Projectile Force.

The Portion of a Circle by this Philoſophy may be as well Reſolv'd into a Centripetal Force and a Secant, as a Centripetal Force and a Tangent.

§. 14. Besides even according to a Law of Motion, which is afterwards alledg'd in the Preſent Philoſophy, where it is ſaid the Diagonal Force is Equal to that of the Sides of a Parallelogram, it is not Neceſſary, that a Body, which deſcribes a Curve, ſhou'd be drawn from the Tangent, or it's firſt Rectilinear Determination, towards the Center of it's Motion; ſince *HE* the Diagonal, which is ſuppos'd to be an Infinitely Small and Strait Line, that is, an Infiniteſima of the Circle, may as well be Expreſs'd by *GE* and *HG* a Secant, as by *FE* and *HF* a Tangent.



The Projectile and Centripetal Direction a Creature of the Mind.

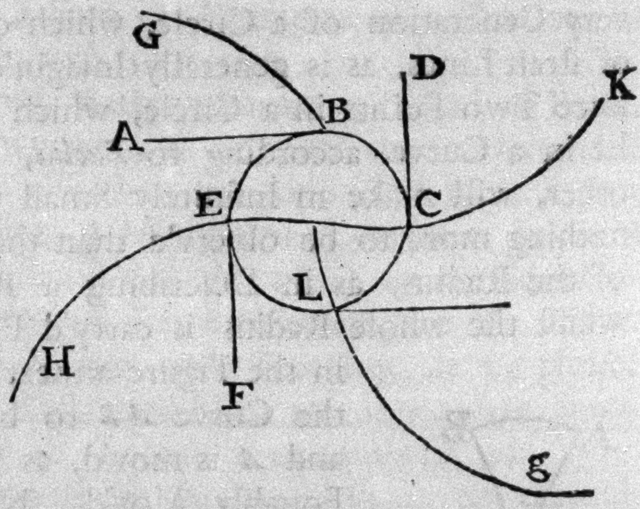
§. 15. That this Projectile or Tangent, and Centripetal Motion is therefore a Creature of the Mind, whilſt it is ſuppos'd neceſſary to Form a Curve, is Evident, ſince, as in §. 12, *A* and *B* may as juſtly be Imagin'd to Tend to *C* and *C* in the ſecond Figure, which yet will not be acknowledg'd, as *A* and *B* to *C* in the Firſt, which conſequently is not prov'd; On the other Hand, *H* may be as Agreeably preſum'd, when the Centripetal Force Ceaſes, to go off in a Secant *HG*, as in a Tangent *HF*, according to the Preceding Section.

A Rectilinear Motion as Compounded, as a Curvilinear, and therefore not more Natural.

§. 16. Farther it is confeſs'd in the Preſent Philoſophy, according to §. 14, that a Rectilinear Motion is Reſolvible into Ten Millions of Determinations, why therefore that ſhou'd be of a Simpler and Plainer Nature than a Motion in a Curve, which cannot well be Reſolv'd into More, is unaccountable; But what is more ſo is, That this Law ſuppoſes a Body to Relinquiſh the Curve, and to Move again in a ſtrait Line, when the External Force Ceaſes, which is to make it Perſiſt in a Rectilinear Motion according to a Force Impreſs'd, but not in a Curvilinear, or to give it an Inertia in the one Caſe, and to take it away in the other; for the Impreſſion is Made, tho' the Force is Diſcontinu'd.

The Inſtance of the Sling Conſider'd.

§. 17. The Inſtance in Fact to prove this Law, is that of a Stone or any other Body mov'd in a Sling, which, when it's Reſtraint is taken off, is ſaid to Proceed in a Tangent, which is ſo far from being true in Reality, that I believe no one ever Found or Experienc'd a Stone to be Slung in a Tangent; For let *CBEL* be the Circle, in which the Sling is Revolv'd from *C* to *B*, *E*, and *L*, if the Projectile goes off in a Tangent, It muſt do it, if we take the chief Points in the Circle, either at *C*, *B*, *E*, or *L*; in the Firſt and Third Caſe, it will be therefore Projected Perpendicular from or to the Horizon; and in the Second and Fourth, Parallel to it, with contrary Directions; whereas in the Second Caſe it is Notorious, that it Proceeds in a Curve not below the Tangent *AB*, which might be ſolv'd by the Gravity of the Projectile, from which it is Determin'd into a Parabolick Circuit, but above it, and by the Force of the bare Projection; and the ſame is very Probable in the other Caſes, in ſome Meaſure and Proportion.



A Conatus to a Motion in a Direct Line from the Center, not the ſame as a Conatus to a Motion in a Tangent.

§. 18. It ſeems to be very plain, that, in this Circular Motion of the Sling, the Body detain'd in it Recedes from the Center by it's Tenſion of it, but how it ſhou'd in every Point retire from the Center, in the ſame Direction with the Radius, and yet depart from it, in a Line Perpendicular to the Radius, is Inconceivable, unleſs it can be affirm'd, that it's Conatus to a Motion in the Tangent, and it's Conatus to a Motion in a Direct Line from the Center, is the ſame Thing; and yet the Conatus to Motion in a Tangent is term'd the Centrifugal Force.

§. 19. We

The Motion of the Sling which is Circular, is not Reducible to any Rectilinear Motions.

§. 19. We cannot but farther ſay, that the Motion of the Sling is to be judg'd of by it's own proper Determination, that is, a Circular, which is no more Reſolvible into any other more Simple ones, as of a Tangent and a Direct Force to the Center, than a Rectilinear Force is, which is ſaid, when conſider'd as a Diagonal, to be Reſolv'd into the Sides of a Parallelogram, of which it is the Diagonal, concerning which we ſhall ſay more afterwards; The Curve of a Parabola is not to be Meaſur'd by any Portion of it's Diameter, it is not Reducible to any Strait Lines, nor is the Circle or rather the Perimeter of it; and as the Curves are Inexpreſſible by any Right Lines, ſo are the Forces likewiſe, ſince the Cauſes and Effects muſt be Proportional; from whence it Enſues, that all Determinations of Curves are in their Motion Peculiar to themſelves, and can be no more Expreſs'd by Right Lines, than Right Lines can be Expreſs'd by them.

The Centrifugal Force of a Sling, as here apply'd, not proper to Explain the Centripetal of the Planets.

§. 20. It is alſo very much to be Queſtion'd, how a Centrifugal Force, as in the Sling, ſhou'd be anſwerable to a Centripetal in the Real Effects of it, and yet the Centrifugal of the Sling is brought to explain the Centripetal of the Planets; for tho' ſo much as it endeavours to Recede from, ſo much it is Kept to the Center, yet the Actual Force is not the ſame, whether it Retires from or Tends to the Center, ſince the one is in a Contrary Direction to the other. If therefore a Body in the midſt of it's Motion is ſet looſe from the Reſtraint it lies under from the Sling, it will not find it ſelf in the ſame Conditions (ſetting aſide the Tangent or Projectile Force) as if it really Tended to the Center, ſeeing the one in an Abſtracted Reaſoning, without conſidering any Foreign or External Action, wou'd make it fall below the Tangent, and the other carry it above it; Not to mention the Peculiar Forces, by which Different Planets tend Differently to their Centers, which cannot be Expounded by the Abſtracted one of a Sling.

Matter is ſuppos'd to be Entirely Paſſive in order to make Motion Rectilinear, which Suppoſition cannot be Granted.

§. 21. Lastly, a Rectilinear Motion is ſuppos'd to be the moſt Natural, becauſe Matter is preſum'd to be perfectly Paſſive and Obedient to the Impreſſions made upon it, and the moſt Simple Impreſſion is Imagin'd to be that of a Right Line; but if Matter is not entirely Paſſive, which has been Prov'd, or if a Curve Line is as much a Single Determination (as it is Peculiar to it ſelf) as a Right Line is, which has been likewiſe Evidenc'd, or laſtly, if a Right Line is or may be Compounded of ſeveral Determinations, as well as a Curve, which this Philoſophy affirms, it is far from being True or Demonſtrable, that Motion is in it ſelf Rectilinear, and conſequently is no more a Law of Nature or Motion, than if we ſhou'd aſſert that Motion in it ſelf is always perform'd in a Curve.

The Third Law of Nature or Motion Explain'd.
Mr. Whiſton's Phyſ. Math. Prælect. 5. Art. 3.

§. 22. A Third Law of Nature or Motion is, That all Bodies, which are Revolv'd upon a Center of Motion, endeavour to Recede from that Center, and the Quicker the Circumvolution is, the More they ſtrive to Retire from it; for ſince Bodies in themſelves affect a Rectilinear Motion, they wou'd proceed in a Tangent of the Curve, which they Deſcribe, if they were not drawn from thence by the Centripetal Force, which Attracts them; which therefore is Contrary and Equal to the Projectile, or the Force Expreſs'd by the Tangent; And conſequently, if the Gyration or Revolution in the Curve is Swifter, that is, if the Central Force, by which it is Retain'd in the Curve, is ſo, the Projectile Force or that, which is Expreſs'd by the Tangent and Repreſents the Centrifugal, muſt be Swifter likewiſe, ſeeing it is exactly Equal to the Former.

Curves are affirm'd to be actually Deſcrib'd by a Centrifugal and a Centripetal Force.

§. 23. As to what concerns Bodies in themſelves Proceeding in a Strait Line, we have in an Abſtracted Reaſoning conſider'd, what Arguments there are to Evince it, and the Inſtance of the Sling made uſe of to Explain it; and from the Whole we cou'd not find any juſt Conviction of the Law of Nature, which was propos'd upon that Principle, and upon the ſame Account alſo, this Third Law is Precarious and Uncertain; we ſhall omit all that has been ſaid before, and at preſent Examine, what is farther Advanc'd in this Law, more than that, which has been already Confuted; for tho' Abſtracted Determinations, ſuch as a Curve Line might be Reſolv'd into by the Mind, were before only modeſtly Introduc'd, we are now plainly told, that they are Actual Forces, which Deſcribe theſe Curves, without any other Proof or Demonſtration of it, excepting that of Pronouncing it.

The Centrifugal and Centripetal Forces are aſſum'd and not prov'd.

§. 24. Since therefore the Motion in a Curve is Actually ſaid to conſiſt in a Centripetal and a Centrifugal Force, which are Equal, the one of which is Expreſs'd by a Direction to the Center, and the other by that of the Tangent to the Curve, we muſt Inquire by what Methods this Law is Prov'd; It is not by conſidering the Curve in an Abſtracted Senſe, as a Mathematical Figure, by what has been before alledg'd; If it is by Real Forces in Nature, thoſe ought to be firſt Prov'd, before they are Aſſum'd, or otherwiſe we cannot but think they are ſuch, which the Philoſopher is pleas'd Arbitrarily to Contrive and make Uſe of, as ſhall beſt Serve his own Purpoſes; For the Attraction to the Center in Bodies, which Revolve in a Curve, is far from being Prov'd by this Law, becauſe this Law, and thoſe, on which this Depends, are Introduc'd to Prove an Attraction, or a Force, which draws the Body from a Tangent into a Curve, that is, towards the Center; and on the other Hand, a Real Projectile or a Rectilinear Force is Equally Unprov'd, becauſe it is Aſſum'd to ſhew, how Curves are deſcrib'd by a Gravitating Force, which is not as yet Demonſtrated.

The Projectile or Centrifugal Force not more Natural than that of Gravitation.

§. 25. In Reſpect of theſe Projectile and Gravitating Forces, it will alſo be juſtly Inquir'd, why the Projectile Force, in the Tangent, ſhou'd be the Natural one, and the Centripetal, in the Curve, ſhou'd be the Impreſs'd; for altho' a Rectilinear Motion were obſerv'd by Bodies left to themſelves after they are once depriv'd of their Reſt, it is yet plain, that they muſt be put into Motion by an External Impulſe, and conſequently, the Effect which Reſults from it, according to the Direction of the Tangent, is as much owing to a Foreign Cauſe, as their being Drawn from that Determination into a Circular or Elliptical, the only Difference being, that the Effect from Impulſe is continued, when the Cauſe Ceaſes, but that from Attraction is Conſtant, as well as the Cauſe which produces it, which can make no Alteration, as to the Forces being Equally Unnatural, and Extraneous to the Bodies which are Mov'd by them; If therefore both the Projectile and Centripetal Force is Impreſs'd upon Bodies mov'd in a Curve, it is well if it is not a Contrivance in the Philoſopher, rather than of Nature, to Project firſt and then Attract the Bodies, whoſe Revolutions are endeavour'd to be Explain'd; eſpecially, ſince they are both Occult Qualities, and no Account is given of them, how they come to Reſide in the Bodies, which they Agitate, and by which they are ſuppos'd to be Retain'd and Continu'd in their Orbits.

The Sling no Proof of a Body's being kept in it's Orbit by a Centripetal Force in the Senſe of this Philoſophy, but by a Centrifugal or Expanſive.

§. 26. We muſt likewiſe add, that the only Inſtance of a Body's being kept in it's Orbit by a Centripetal Force is that of a Sling, which Really is a Centrifugal, and, as we in part before obſerv'd, cannot be Compounded of a Tangent or Projectile Force, and a Centripetal, ſince the Projectile is ſaid to be Natural to a Body once put into Motion, and conſequently that Force, namely the Centripetal, which draws the Body from a Tangent into a Curve, and therefore is Superior to the Projectile, ſhou'd be ſenſible to the Hand, which Revolves the Sling, whereas it perceives no ſuch Force, but the Contrary, that is, a Conatus of the Body to Recede from the Center; This is alſo confirm'd by the Revolution of a Globe round it's own Axis, which, if in the Interim of it's Motion any Liquid is pour'd upon it, will not throw it off in Tangents, but diſperſes it every Way, and, inſtead of caſting it in Horizontal Lines, makes ſome parts of it Aſcend into the Air it ſelf, which is an Evident Argument, that the Circular Motion of a Body is neither Centripetal, whilſt it has an Oppoſite Direction, nor Projects in a Tangent, whilſt it Repells what comes in it's Way in a Perpendicular Direction, as well as an Horizontal, and in all other Intermediate ones.

The Centrifugal Force cannot be the ſame as the Centripetal.

§. 27. If it is ſaid, that the Force of Retiring from the Center is the ſame, as that of Tending to it, upon the Account of Action and Re-action being Equal, whatever that Law is, which we ſhall afterwards Conſider, no Law in the World or in Nature can make Two oppoſite Directions of Motion from a Point and to a Point to be the ſame.

If the Centrifugal and Centripetal Forces are Equal no Motion in a Curve will Enſue.

§. 28. There is another Thing affirm'd in this Law of Nature or Motion, which is, that the Centripetal or Attractive Force to the Center is exactly Equal to that of the Centrifugal or Projectile; If ſo, it wou'd be Impoſſible there ſhould be any Motion in a Curve at all; For if the Projectile Force endeavours to Proceed from the Point of Contact of the Tangent with the Curve with the ſame Energy or

Action, with which the Attractive Force inclines to the Center, the Attractive cannot draw the Body, which is in a Projectile Motion, from that Point, becauſe it is not Superior to it, and all that can follow will be only a perfect Quieſcence; Since if contrary Forces, which Differ in nothing excepting in their Direction, are in an Equal Balance, the Reſult muſt be that of no Motion at all.

The Centrifugal Force or the Projectile in a Tangent being at a Right Angle with the Centripetal cannot account for their Forces being in an Æquilibrium.

§. 29. **THAT** which makes this Doctrine more Unaccountable is, that the Centrifugal and Centripetal Forces, which in Deſcribing a Curve are ſuppos'd to be in an Æquilibrium, and which it is Impoſſible they ſhou'd Deſcribe, if they were in an Æquilibrium, according to the Preceding Section, that we ſay, which makes it more Unaccountable is, that the Centrifugal and Centripetal Forces are not in a Direct Oppoſition to each other, but in a Right Angle, the Projectile going off in a Tangent, and the Centripetal or Attractive Tending to the Center in a Radius Perpendicular to it; for where Forces are Oppoſite or Contrary, it is eaſy to Imagine an Equal Balance betwixt them, if the Forces are Equal, but where they are in a Right Angle the one to the other, it is not, nor can be Prov'd, that they are in an Equal Balance; Becauſe if the Projectile Force is Equal to the Attractive, according to the Suppoſition of this Philoſophy, and that Equality is had and found in Forces which are Contrary to each other, it is Impoſſible it ſhou'd be in Forces, which are not Contrary to each other, and are in a Right Angle only in their Mutual Direction; If an Equality of Forces may be affirm'd without Contrary Directions, it will lie upon this Philoſophy to Prove, what Proportion of the Projectile Force will be exactly Agreeable and Analogous to the Attractive, which it has not done; ſince it Aſſumes both of them, and after that does not Inform us, what Quantity of Motion there is in the Projectile or Attractive to make them Equal, where their Directions are at Right Angles.

From what Forces the Circular Motion of a Stone in a Sling ariſes.

§. 30. **THE** Circular Motion of a Stone in a Sling Ariſes therefore, not from a Centripetal Force, by which it tends to the Center of it's Revolution, and from a Centrifugal, which Acts in the Direction of a Tangent, but from a Centrifugal or Expanſive, Communicated to it by the Expanſive Force of the Hand's Motion, which is Diametrically Oppoſite to the Centripetal of the Stone, and by which it is overcome, and made to Revolve in the Orbit preſcrib'd to it by ſuch Expanſive Force.

THE Stone in this Caſe, tho' it is Endu'd with a Power of Gravity, or of Deſcending to the Earth, yet finds that Inclination and Propenſity actually Deſtroy'd by the Contrary Force of the Expanſive Impreſs'd upon it, as if a Body is Projected Perpendicularly from the Earth with a certain Velocity, the Force of Gravitation or Deſcending downwards Ceaſes, till the Velocity is Spent; and if the Expanſive Force by the Revolution of the Hand is imparted in a Circle, for the ſame Reaſon the Stone will not actually Deſcend, nor will have any Inclination to it, ſo long as that Force Continues, and ſo far is it from being True, that the Centripetal and Centrifugal Forces are Equal, that the Centripetal Force is ſuperſeded and ſurmounted by the Centrifugal.

THUS in any Two Forces acting Contrary to each other, whilſt the one Prevails, the other Submits; If a Body is carry'd by a Superior Velocity one way of $+12$, and another is carry'd with a Contrary, but with a leſs Force of -5, the contrary Force will be Deſtroy'd, and there will be an Exceſs of the Superior Velocity of $+7$, and if there were an Æquilibrium of Two oppoſite Forces, there wou'd not be a Revolution, as in the Sling, or a Motion, as in contrary Velocities, but a perfect Quieſcence.

LIKEWISE, the Centrifugal or Expanſive Force has not it's Direction in a Tangent, but as the Centripetal Force is entirely Vanquiſh'd and Subdu'd, and the Stone is only Detain'd by the Obſtacle of the Sling from Retiring from the Expanſive Force Imparted by the Motion of the Hand, ſo the Expanſive Force, which it acquires from thence, is Directed by the ſame Circular Motion, and is therefore Circular, and we may as well affirm, that the Hand Moves in a Tangent, as that the Stone in the Sling affects ſuch a Motion, we have ſhewn that the Stone in a

Sling has no ſenſible Centripetal Force, and we may add, that if it had one to the Earth, it can with no Manner of Reaſon be ſuppos'd to obtain one to the Center of the Sling's Motion, but if it has neither of theſe Centripetal Forces, what ſhou'd give the Centrifugal the Direction of the Tangent? Effects are not produc'd without their Cauſes, and there is no Imaginable Cauſe of the Expanſive or Centrifugal Acting in that Direction, unleſs we will ſuppoſe the Hand acts in a Tangent, when it acts in a Circle, and that a Tangent and a Circle are the ſame; 'Tis known from whence all this Doctrine proceeds, in Reſpect of the preſent Philoſophy, Namely, from it's eſpouſing Projectile and Centripetal Forces, and the firſt Hint, which was given of Reaſoning in this way of Tangents to a Circle, was from *Des-Cartes*, whoſe other Notions have been either Deſpis'd or Confuted by this very Philoſophy, but the Preſent retain'd for the Valuable Conſideration we have mention'd.

Des-Cartes's Princip. Philoſ. Part. 2. §. 39.

The Application of this Doctrine to the Revolution of the Planets round the Sun by Means of the Expanſive and Contractive Forces, as well as about their own Axes.

§. 31. LET us now apply this to the Revolution of the Planets Round the Sun, and if what we have before propos'd upon that Subject is not Satisfactory and Convincing, where we alledg'd the Balance for an Explanation of it, and made the Sun to be the Center of Detention, and the Planets to have a Greater Force of Expanſion and Velocity, the farther they remov'd from it, perhaps what we here offer may be a farther Confirmation of ſuch a Doctrine.

IT is acknowledg'd therefore, that the Sun has an Immenſe Expanſive Force, by which it diffuſes it's Light and Heat to a Prodigious Diſtance, much beyond our Earth and to the very Orb of *Saturn*; we have ſaid, that the Reaſon why the Solar Heat is not ſo Intenſe here, ſeems to proceed from the Moon's being plac'd ſo near us, which we take to be a vaſtly Cold and Contractive Body, and therefore qualifies that Exceſſive Heat, which wou'd otherwiſe Burn up the whole Globe; and therefore, notwithſtanding the Moderate Heats, which are perceiv'd in this Earth, in Reſpect of the Sun's Immenſe Expanſive Force, ſuch Force may yet be propagated with a ſufficient Degree of Heat, as it is of Light, to *Saturn*.

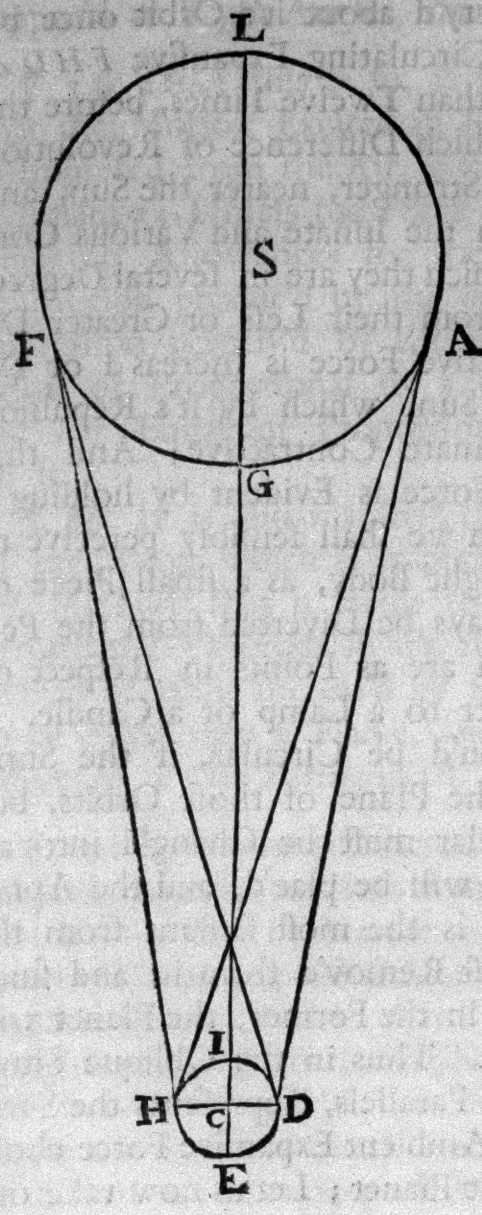
'TIS alſo confeſs'd, that the Sun is Revolv'd about it's Axis, and that the Earth and the Planets, in Reſpect of the Sun as their Center, are but as ſo many Points; If therefore the Expanſive Force of the Sun is ſo Great, and the Earth and Planets are but as Points to the Body of it, we may juſtly think, that they are carry'd Round it, like a Stone in a Sling, and that their Contractive or Gravitating Forces are oblig'd to obſerve the Directions of the Sun's Expanſive, by which means they will all Revolve the ſame Way, and Perform their Gyrations according to the Proportion, which there is betwixt the Expanſive of the Sun and the Gravitating or Contractive of the Planets, which are Revolv'd, and that the Infinite and Almighty Agent, by Impreſſing this Force upon the Sun, Directs and Guides the Motion of the whole Solar Syſtem; That this Expanſive Force of the Sun Diffuſes and Diſperſes it ſelf thro' the whole Ambient Plenum, as far as *Saturn*, and Affects it in like Manner, as it ſelf is Affected, not only in Reſpect of it's Light and it's Heat, which is Evident and Confeſs'd, but in Reſpect of it's Revolution, by which all the Planets will Revolve round their own Axes the ſame Way, and at the ſame Time Deſcribe their Periods about the Sun.

THUS alſo it is acknowledg'd, that the Atmoſphere is Revolv'd with the Earth; that all Bodies obey the Motions of their Syſtems; that Contractive Bodies are diſſolv'd in a Syſtem of the Expanſive Force, as Metals and Minerals in Spirit of Nitre; and Expanſive Bodies reduc'd to a Syſtem of the Contractive Force, as in Chryſtallizations, and in the Gravitation of all Bodies to the Earth, tho' they are never ſo Light and Expanſive.

Why the Planets are Revolv'd from Weſt to Eaſt, and not the Contrary. Dr. Gregory's Aſtronom. §. 5. Prop. 30. Lib. 1. Dr. Keill's Aſtronom. Lect. 5. P. 47.

§. 32. THE Sun is obſerv'd to Revolve from Weſt to Eaſt about it's Axis, from the Rotation of it's Maculæ in 25 or 27 Days, which Axis is inclin'd to the Plane of the Earth's Orbit, in an Angle of about 7 Degrees, If therefore the Sun Attracted the Planets, it would make them Revolve from Eaſt to Weſt contrary to Experience. Thus in the Figure annex't, If *AH*, *AD*, *FD*, *FH*, and *GC*, and all the Intermediate Lines ſhou'd Repreſent the Sun's Attractions in *S* of the Earth or any other Planet in *C*, ſuppoſing now the Sun to be Revolv'd round it's Axis from Weſt to Eaſt, or from *F* to *A*, the Attraction of *D* to *A* wou'd immediately Ceaſe, or be continually

Diminiſh'd,



Diminiſh'd, but there wou'd ſtill remain that of *H* to *A*, and *H* to *F*, which, as *A* mov'd towards *L*, and *F* towards *G*, wou'd Draw and Impell *H* towards *D*; and ſince the ſame wou'd happen in the next Point to *H* towards *E*, and to all the following ones from *H* to *E* and *D*, and ſo round the Earth's Circumference, it is manifeſt, that the Earth or Planet wou'd be Revolv'd from *H* to *I* and *D*, and from *D* to *E* and *H*, or in a contrary Direction to that of the Sun, which is ſuppos'd to be carry'd from *F* to *G*, and from *G* to *A*; for if it was carry'd in the ſame Direction, it would move from *H* to *E*, and from *E* to *D*.

On the other Hand, if we ſuppoſe the Sun to be endu'd with an Expanſive or a Repulſive Force, it will cauſe the Planets to Revolve round their Axes the ſame Way, that is, from Weſt to Eaſt. Thus, as before, whilſt the Repulſive Force of the Sun is mov'd from *A* towards *L*, it's Effect Ceaſes, or is Diminiſh'd in the Repelling of *D*, but Continues and Exerts it ſelf from *A* to *H*, by which *H* is Thruſt and Protruded towards *E*; The Repulſive Force from *F* to *D* is more Oblique than that from *F* to *H*, and therefore Weaker, and moreover is continually Diminiſh'd, as *F* comes to *G*, and conſequently the Repulſive from *F* to *H*, will ſtill Forward and Promote the Revolution of *H* towards *E*; and ſince, in the Motion of *F* towards *G* or *A*, the ſame will happen to any Point next to *H* towards *I* and *D*, it is plain, that the Revolution of the Planet will be from *H* to *E*, and from thence to *D* and *I*, and ſo to *H*, that is, from Weſt to Eaſt, and in the ſame Direction with the Sun's Gyration about it's Axis, which is a Problem, that has not been hitherto ſolv'd; and particularly, *Venus* is Revolv'd round it's Axis in 23 Hours from Weſt to Eaſt, the *Earth* in 24 Hours, *Mars* in 24 Hours 40 Minutes, and *Jupiter* in 9 Hours 56 Minutes, *Mercury*'s and *Saturn*'s Revolutions are not aſcertain'd, the one being too near the Sun, and the other too diſtant from us, for an Obſervation of it's Maculæ, whilſt the Sun is 25 or 27 Days in Revolving; The Reaſon of which is, becauſe the Sun may Propell *HEDI* quite round it's Axis, which is but a ſmall Body in Compariſon of it, whilſt the Sun ſhall perform only $\frac{1}{27}$th of it's Revolution, as in *Venus*, the *Earth*, and *Mars*, and not half ſo much, as in *Jupiter*, if *Caſſini*'s Obſervations are True, which perhaps may be Uncertain.

Sir Iſ. Newt. Optic. Quer. 28. Pag. 334. Octav.

But beſides, this Expanſive Force of the Sun, by which it throws the Planets round upon their Axes in the ſame Way and Direction, in which it is Revolv'd about it's own, will alſo carry the whole Planet round the ſame Way, in which it is Mov'd, for if all the Lines *FH*, *FD*, *GC*, *AH*, *AD* are ſuppos'd to be carry'd together in a Revolution from *F* to *A*, and from thence to *L*, the Planet *HEDI*, which is in the midſt of ſuch a Moving or Revolving Action, will be Determin'd the ſame Way, like a Stone in a Sling, as we before mention'd, and which has been the Inſtance, made uſe of by Philoſophers, to Explain the Imaginary Projectile and Centrifugal Force of the Heavenly Bodies. Here is therefore an Account given, why the Planets Revolve about their Axes and in their Orbits the ſame Way, which will agree with what we have already offer'd concerning them.

§. 33. The only Difficulty, which remains to be ſolv'd, is, why their Periods about their Axes and in their Orbits are Different, and why thoſe Orbits are Excentrical and Elliptical, and not Circular; As to the Firſt, *Mercury* Revolves about the Sun in 3 Months, *Venus* in ſomething more than Eight, and the *Earth* in Twelve or one Year, *Mars* in 2 Years, *Jupiter* in 12, and *Saturn* in 30; in Reſpect of which it is Evident, that the Nearer the Planets are in General to the Sun, the Quicker is their Revolution, and the Farther they are Remov'd from it, the Slower, which perfectly Correſponds

Why the Periods of the Planets are Various and are Perform'd in Ellipſes, and how the Revolutions of the Secondary Planets are ſolv'd.

Sir Iſ. Newt. Princip. Par. 3. Dr. Gregory's Aſtronom. Dr. Keill's.

ſponds with what we affirm, that the Expanſive Force is Stronger, nearer to the Sun, and Weaker, at greater Diſtances from it; ſo that the Sun ſhall Revolve more than three Times round it's Axis, before *Mercury* ſhall be carry'd about it's Orbit once by a Continual, Conſtant, and Uniform Impulſe of the Circulating Expanſive *FHDA*, and more than Eight Times, before *Venus* is, and more than Twelve Times, before the *Earth* is, and ſo on of *Mars, Jupiter,* and *Saturn*; and which Difference of Revolution does not only proceed from the Expanſive Force being Stronger, nearer the Sun, and Weaker, the farther it Acts from it, but likewiſe from the Innate and Various Contractive Forces of the Planets, which are Revolv'd, by which they are in ſeveral Degrees Renitent and Reluctant to the Expanſive, as well as from their Leſs or Greater Diſtances from the Sun, by which their proper Contractive Force is Increas'd or Diminiſh'd; 'Tis alſo the ſame Expanſive Force of the Sun, which by it's Repulſion keeps the Planets from Gravitating to it by their Innate Contractive; And that Fire and Flame Obtain this Expanſive and Repulſive Force is Evident by holding a Feather over the Flame of a Lamp or a Candle, which we ſhall ſenſibly perceive to be Agitated and Repell'd by it, and by Letting any Light Body, as a ſmall Piece of Paper, fall Perpendicularly over it, which yet will always be Diverted from the Perpendicular by this Repulſion; But the Planets, which are as Points in Reſpect of the Sun, will not be much more to it, than a Feather to a Lamp or a Candle.

As to the Second, theſe Orbits of the Planets wou'd be Circular, if the Sun's Axis, on which it is Revolv'd, was perpendicular to the Plane of thoſe Orbits, but being Inclin'd, what otherwiſe wou'd have been Circular muſt be Chang'd into an Ellipſis; In the Focus or Umbilicus of which the Sun will be plac'd, and the Aphelium of the Orbit will be in that Part of it, which is the moſt Diſtant from the Sun's Horizon, and the Perihelium, where it is the leaſt Remov'd from it, and ſince the Expanſive Force is Greater in the Latter Caſe than in the Former, the Planet will move Faſter in the Perihelium than in the Aphelium. Thus in the Oblique Situation and Rotation of the Globe, the Æquator, and it's Parallels, Repreſents the Sun's Revolution about it's Axis, together with that of the Ambient Expanſive Force about the Sun, the Ecliptick expreſſes the Inclin'd Orbit of the Planet; Let us now take one Point of it, namely *Capricorn*, and place it under the Meridian, which wou'd be carry'd round in the Diurnal Circle belonging to that Tropick, by the Revolution of the Sun's Expanſive, if the Planet was not oblig'd to perform it's Orbit in a Plane about the Sun, which the Tropical Circle is not, from whence the Oblique Diurnal Circle Projected on the Vertical Circle, which ſtands at Right Angles with the Meridian, or any other Circle Parallel to it, becomes an Ellipſis, whoſe Perihelium is in *Capricorn*, as being neareſt to the Sun's Horizon, and whoſe Aphelium is in the Point oppoſite to it, and which is the fartheſt from the ſame Horizon, ſuppoſing the Tropick of *Capricorn* is brought to the Meridian; On the Contrary, the Tropical Circle of *Cancer*, Projected on the aforeſaid Vertical, Forms an Ellipſis, whoſe Aphelium is in *Cancer*, and the Perihelium in the Point oppos'd to it, and ſince all the Intermediate Diurnal Circles are to be Projected on the ſame Vertical, they will be Elliptical, and the *Earth*'s Orbit or the Ecliptick will be an Ellipſis, whoſe Perihelium is in *Capricorn*, and the Aphelium in *Cancer*, according to what is Experienc'd by Aſtronomers.

The Revolutions of the Secondary Planets about their Axes, and in their Orbits round the Primary, as the Moon and the Satellites of *Jupiter* and *Saturn*, may be accounted for the ſame Way, excepting, that here Contractive Forces, which Act oppoſite to each other, are to be Aſſum'd inſtead of the Expanſive of the Sun and the Contractive of the Planets; For an oppoſite Contractive has the Force of an Expanſive, as we have already ſhewn.

The Fourth Law of Nature or Motion Explain'd. Mr. Whiſton. Prælect. 5. Phyſ. Math. Art. 4. Dr. Keill's Introduct. Lect. 11. Lex. 2. Sir Iſ. Newt. Princ. Lex. 2.

§. 34. The Fourth Law is, that the Change of Motion is Proportional to the Force of Motion, which is Impreſs'd, and is made according to the Right Line, by which the Force is Communicated; Thus if any Motion is Generated by a given Force, a double Motion will be produc'd by a double Force, and a Triple by a Triple, *&c.* whether ſuch Force is Impreſs'd at once, or Succeſſively, and by Degrees; and ſince Motion is determin'd to that Part, towards which the Force directs it, if a Body is in Motion before, the Force Impreſs'd, and which conſpires with it, will make an Addition to the Former, or, if it is contrary, will make a Subſtraction from it, and in the firſt Caſe will Increaſe the Motion, and in the laſt Diminiſh it; if therefore the Force more or leſs Conſpires with or Acts contrary to the former Motion, in different Degrees of Obliquity it will more or leſs Increaſe or Diminiſh it, and, if they are Oppos'd at Right Angles, there will be no Increaſe or Diminution of it.

§. 35. **That** this is ſo, is far from being True, for we plainly find in Experience, that the Motion Excited in Fire is not Equal or Proportional to the Force, which is Impreſs'd from the Air, either Naturally or by any Artificial Methods, by which it is Inflam'd; Unleſs the Force of Air, Impreſs'd upon the Hand, has the ſame Effect (making Allowances for the Original Motion of the Fire) with the Difference of Motion produc'd by the ſame Force of Air Impreſs'd upon Fire, and after ſuch Impreſſion perceiv'd by the Hand, that is, Unleſs a certain Degree of Coolneſs is Equal or Proportional to a certain Degree of Heat, and therefore the Force of the Air Equal or Proportional to the Motion or Force produc'd in the Fire by it.

Objection the Firſt againſt this Law, that the Motion of Fire is not Proportional to the Motion of Air Impreſs'd.

§. 36. **It** is alſo manifeſt, that, in Fire and Flame, it ſo little obſerves the Direction of the Force, which is Impreſs'd upon it from the Air, Naturally or by any Artificial Methods, that it ſeems to be Reluctant to and to oppoſe it, where it is not too Strong and Vigorous in it's Action, and where it is, to Die and Languiſh under it, inſtead of being Increas'd by it; And thus we find ſmall Sparks, by a Gentle Fanning, to be rais'd into a Flame, and, on the Contrary, by an Exceſs of Force in the Air Impreſs'd, to be Extinguiſh'd.

Objection the Second, That the Motion of Fire by a leſſer Force of Air is Increas'd, and by a Greater Diminiſh'd.

§. 37. **If** ſuch an Inſtance, as that of Fire, which we have mention'd, is Rejected as Abſurd, becauſe we know nothing of the Philoſophy of it, we muſt at leaſt ſay, that it is a Part of Nature and Deſerves as much to be Explain'd and Taken into the Laws of it, as any other Material Being whatſoever; For it will, in Spite of all our Hypotheſes contriv'd to ſolve the Grand Appearances of the Revolutions of the Heavenly Bodies, be an Invincible Objection againſt them, if they cannot Account for Effects in Nature, which are Near us, which are Conſtantly under our Eyes, and are Open and Plain to Every one's Obſervation; It will only be Evident, that ſuch Laws of Nature are Mere Hypotheſes and Suppoſitions, Invented in Order and with a Deſign to explicate, if poſſible, ſome Mighty Phænomenons, which the Philoſopher has in View, without Regarding, and in Contempt of thoſe others, and as he is pleas'd to Think Meaner, with which we are daily Converſant, and perhaps, for that Reaſon, becauſe they are ſo vulgarly known.

The Motion of Fire ought to be Explain'd in a true Philoſophy, as well as the Motion of Heavy Bodies, which the Sun and Planets are ſuppos'd to be.

§. 38. **Albeit** the Deſign and Intention of the preſent Law of Nature is really nothing elſe, than what we have Declar'd in the foregoing Section, and Fire or Flame is excluded from Nature, becauſe in Reality it is too Active for a Dull and Phlegmatick Philoſophy to Explain, whilſt other Inertial Bodies are only Conſider'd, Which it is Preſum'd we can Manage and Put into Motion as we pleaſe, I ſay, notwithſtanding this, we ſhall Enquire farther, whether this Law is Expreſsly Applicable to any other Matter Different from Fire, which we can Name, and which may, perhaps, ſeem more Tractable and Obedient to the Laws, which Philoſophers ſhall Think fit to Impoſe.

Inertial Bodies only conſider'd in this Philoſophy.

§. 39. **If** we take an Elaſtick Body, or a Hard, or a Soft, or a Viſcous, which is Endued with ſome particular Force or other of it's own, it is Impoſſible the Change of Motion ſhou'd be Proportional to the Force, which is Impreſs'd, becauſe that Occult and Unknown Force, at leaſt in the Preſent Philoſophy, by which a Body becomes Elaſtick, or Hard, or Soft, or Viſcous, *&c.* will have a Power of making ſome Alteration or other in the Force, which is Impreſs'd, if ſo, then, altho' a ſingle Force produces a certain Motion, a Double will not produce the Double of it, ſince that Alteration, which is made in the Force Impreſs'd by the peculiar Power of the Natural Body, will unavoidably cauſe the Motion not to be Proportional to the Force; For let the Single Force be 2, and the Double 4, and the Alteration made in the Forces by the Power of the Body it ſelf 1, The Effect or Motion, in the firſt Caſe, will be as 1, and, in the Second as 3, which evidently are not as 2 to 4; When we ſay the Alteration is as 1, and Subſtract it from the Force Impreſs'd, we only put it as an Inſtance, for let the Alteration be what it will, it muſt be Expreſs'd by ſome Quantity, which is either to be Added to or Subſtracted from the Forces Impreſs'd, ſo as to make a real Alteration in them, and let this be done any Way, the Reaſoning is

If Bodies have any kind of Force belonging to them, as all Elaſtick, Hard, Soft, and Viſcous Bodies have, the Motion Impreſs'd will not be Proportional to the Motion Receiv'd.

the ſame againſt Motion being Proportional in Natural Bodies to the Forces, which are Impreſs'd.

If Matter is unactive, we may as well take a Cypher as Matter, and argue upon the Motions of it, with as much Penetration and Sagacity.

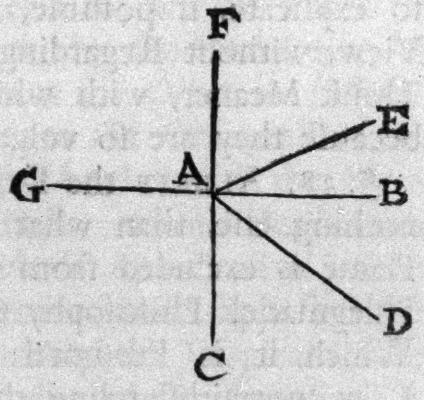
§. 40. Lastly, If we ſuppoſe Matter or Body to be Anſwerable to the Abſtracted Idea of a Solid and Extended Subſtance, which we have Examin'd in the Firſt and this Second Part of our Philoſophy, and ſhewn the Abſurdity and Falſity of ſuch a Notion, that is, if we conſider Matter to be an Idle and Inſignificant Being, which we can Toſs about and Generate juſt as much Motion in it, as we judge convenient to Impreſs, 'tis true, Motion will be Proportional to the *Vis Motrix* which produces it; becauſe this is nothing more than an Identical Propoſition, that the Force which produces any Motion will be Equal to it ſelf, ſince the Effect or the Motion Produc'd, is Equal to the Force or Cauſe which Produces; But of what Service can ſuch an Identical Propoſition be to the true Knowledge of Things, where inſtead of Matter we may as well take a Cypher, and affirm, the Cauſe and Effect being Reciprocal, that Two Acting upon Nothing, the Reſult will be Nothing but the Action of Two? which is wonderfully Sagacious and Penetrating, as well as very Philoſophical and Inſtructive.

The Oblique Directions of Motion not accounted for.

§. 41. Moreover, Granting even this Abſtracted Idea of Motion ſeparate from all Real, the Law of which, as it is here Eſtabliſh'd, being found in no Material Being, which can be mention'd, yet, which is extreamly Unfortunate, this Philoſophy does not account for the Oblique Directions of the Force Impreſs'd, and the Motions, which Reſult from them, altho' no Active Matter is introduc'd to diſturb them, for §. 34. it is ſaid, that if any Motion proceeds in a Direct Line, and a Force acts upon it at Right Angles, there will be no Diminution or Increaſe of the Motion, that in an oppoſite Direction there will be a Diminution of it, and where the Direction of the Force and the Motion Conſpire, an Increaſe, and ſuitably, in all the Intermediate Degrees of Obliquity, the Force and the Motion are variouſly compounded of the Concurring and the Oppoſite.

A Force acting in Right Angles upon a Motion cannot be ſaid neither to give an Increaſe nor a Diminution to it.

§. 42. But in Relation to the foregoing Section muſt we not ask, how all this is Prov'd? It is Plain, if *C* Acts in *A* with the Force *CA* Equal to the Motion *AF*, it will make an Addition of *CA* to *AF*, if they Conſpire, or if they are Oppoſite, there will be a Quieſcence in *A*; if therefore *C* Acts in or upon *A* with the Force *CA* Equal to the Motion *AB* or *AG*, ſuppoſing the Motion on both Hands to proceed from *A* to *B* or *G* at Right Angles, the Force will have an Equal Influence, that is, ſo far as not to determine the Motion from *A* to *B*, or *G*, notwithſtanding which, it wou'd be Ridiculous to Affirm, that an Action in or upon *A*, from *C* to *A*, makes no Alteration in the Motion, from *A* to *B* or *G*, no more than if *A* ſhou'd proceed to *B* or *G* by it's Motion without any Impreſſion upon it in *A*, which yet this Philoſophy does Affirm.



The foregoing Section farther Explain'd.

§. 43. We are conſequently farther to take Notice, that *CA* the Force may be Oppoſite to *FA* the Motion or in the ſame Direction with *AF*, a contrary Motion to the Former, in the firſt Caſe there is an abſolute Privation of Motion, and in the Second it is made Double of what it was before, it will therefore be Impoſſible to ſay with any Reaſon or Truth, that the Force from *C* Acting on *A* is the ſame, whether *A* moves to *B*, or *B* to *A*, that is, *A* to *G*; For if there is this Difference, that whilſt *C* Acts on *A* and *A* moves to *F*, there is a double Force or Motion, whereas on the Contrary, where *F* moves towards *A* there is a perfect Quieſcence, why *C* Acting towards *A* (whether *B* moves to *A* or *A* to *B*) ſhou'd produce no Influence at all upon ſuch oppoſite Forces, as thoſe from *A* to *B*, and *B* to *A*, or *A* to *G*, where it obtain'd ſo conſiderable a one before, is Inconceivable; And the ſame Reaſoning will hold in the Oblique Force of *CA* in Reſpect of the Motion *AE* or *AD*.

The Caſe is, if *F* moves to *A* and *C* to *A*, they will deſtroy each other, ſuppoſing their Forces Equal; If *CA* moves againſt *EA*, it will be Superior to it, if againſt *BA*, it will be ſtill more ſo, if againſt *DA*, it will be Increas'd, till at length a double Force unites in *CA* by an Infinitely ſmall Obliquity of *AD* to *AC*; The Contrary of which will happen, if *C* moves to *A* and *A* to *F*, which will make a double Force, and, in the Infinite Obliquity of *A D*, *A* will move to *D*, whilſt *C* moves or acts to *A*, by which means both their Motions or Forces will be deſtroy'd; ſo that, in the firſt Caſe, there are all the Intermediate Degrees of Motion according to the Various Obliquity of the Forces from 0 to 2, and in the laſt, from 2 to 0.

§. 44. A Fifth Law is, that Re-action is always Equal and Contrary to Action, that is, the Actions of Two Bodies, betwixt one another, whether they are Actions of Impulſe or Attraction, are always Equal, and have contrary Directions; Thus whatever Preſſes or Draws a Thing, it is ſo much Preſs'd or Drawn back by that Thing: For Firſt, If any one Preſſes a Stone with his Finger, there is an Equal Repreſſure of the Stone upon the Finger. Second, If a Horſe Draws a Stone by the Mediation of a Cord, the Stone Draws Back the Horſe with the ſame Force, ſince the Cord, being ſtretch'd on both Hands, will Equally Urge the Horſe towards the Stone, as the Stone towards the Horſe, and will hinder the Horſe from going any farther, than the Stone is mov'd forward. Third, If any Body is carry'd againſt another, and induces upon it a Change of it's Motion, the ſame Change in like manner will alſo be Impreſs'd back upon the Incurring Body, which cauſes the Alteration, and in a contrary Direction, upon the Account of the preſent Law of Action being Equal and Contrary to Re-action; that is, the Repulſe of the Body, whoſe Motion is Chang'd, is Equal to the Impulſe of the Body, which Changes it.

The Fifth Law of Nature and Motion Explain'd.

Mr. Whiſton's Prælect. 5. Phyſ. Math. Art. 5.

Dr. Keill's Intr. ad Ver. Phyſ. Lect. 12. Lex. 3.

Sir Iſ. Newt. Princ. Math. Lex. 3.

It is in this Philoſophy annex't by Way of Caution, that we do not confound Velocity with Motion, for tho' by this Law the Changes of the Motions in Bodies are Equal, thoſe of the Velocities are not, which will be in a Reciprocal Proportion to their Bodies; becauſe the Changes of Motion are Equal, and any Motion is Equal to another, where 10 of Velocity for Inſtance into 3 of Matter is on one Hand Equal to 10 of Matter into 3 of Velocity on the other, and therefore, altho' the Motions are Equal, the Velocities may be as 3 to 10.

§. 45. As to the firſt Inſtance, it can ſignify nothing to the Proof of ſuch a Law, for altho' when I Preſs my Finger upon a Stone, which Reſiſts it, there is a Repreſſure at leaſt Equal to it, it is not certain there is not a Greater, unleſs, becauſe I Preſs with a certain Force, it is taken for Granted, that the ſame Force is Return'd upon that Preſſure; for in Fact it is Evident, that I can Preſs with my Finger, with a Greater or Leſs Force upon a Reſiſting Body, as a Stone; if therefore the Force of Repreſſure is Equal to it, the Stone will have a Power in it ſelf of Repreſſing in Proportion to the Preſſure of my Finger, or not; if it has, it's Proper Reſiſtance is not certain, but varies, as the Action or Impulſe of my Will varies, which is Impoſſible; if it has not, then the Preſſure, which is deriv'd from my Mind, is not always Equal to the Repreſſure of the Body, upon which my Finger by the Direction of it Acts; if it is neither the one, nor the other, but an Abſtracted Idea of Action and Re-action, that ſo much as I Act, ſo much is the Effect of that Action in Reſpect of that, which Acts, and therefore the Cauſe muſt be ſenſible of the Effect, as well as the Effect of the Cauſe, ſuch an Action and Re-action is a Creature of the Mind, and is of no Importance to the Solution of Real Nature; becauſe it only comes to this, that if one Thing has an Influence upon another, that Thing, which is Influenc'd, muſt always have an Influence upon, or a neceſſary Connexion with and Relation to that, which Influences; which is true thus far, that when we Feel we Re-feel, if it may be call'd ſo, that is, when the Mind Acts upon a Body by it's Organs of Senſation, it Perceives what it does, that is, Body Re-acts upon the Mind; when we Preſs a Finger upon a Stone, we feel that Preſſure from without, that is, the Stone Repreſſes, but this Information from without tells us no more, than that we Feel, and not at all, what the Real Action of that Body is, which we Feel; if therefore we take only ſo much Action of the Body, which we Perceive by our Preſſure upon it, we make the Real Nature of Bodies to conſiſt in the Perceptions of our Minds, which is again to affirm External Nature to be a Creature of the Mind, or our own Fancies; for it is Impoſſible, moreover, to ſuppoſe, that the Action of the Finger, directed by the Mind, ſhou'd be the ſame, or have the ſame Effect, in the Return of the Action to the Mind, whether the Preſſure be made by it, upon a Stone, or upon Water, or on Fire; Since it is altogether Abſurd to think, that the Action of the Finger is Equal to

Re action not Equal and Contrary to Action from the Finger preſſing upon a Stone, and being Equally and Contrarily Repreſs'd by it.

that, which Reſiſts it, as in a Stone, or which Yields to it, as in Water, or which Reacts, as in Fire, with a Power Superior to the Preſſure.

The Second Inſtance conſider'd of a Horſe drawing a Stone.

§. 46. The Second Inſtance is; that of a Horſe Drawing a Stone by an Intermediate Cord betwixt them, by which the Equality of Action and Re-action is ſuppos'd to be Prov'd; but who does not ſee, that, if the Stone is Drawn by the Horſe, the Action of the Horſe is Superior to the Re-action of the Stone, or, on the Contrary, if the Stone is not Drawn by the Horſe, the Re-action of the Stone is Superior to the Action of the Horſe? If it is ſaid, that the Horſe and Stone move together, and that if the Horſe does not move, the Stone does not, and if the Stone does not move, the Horſe does not, it is a trifling Way of Proving, that Action and Re-action are Equal, If the Force of the Horſe is Greater than that of the Stone, when he Draws it forwards, or that of the Stone is Greater than that of the Horſe, when it is Impoſſible for him to ſtir it; for, as in the former Caſe of Preſſure in the Finger and Repreſſure from the Body, it is no more than to ſay, we Feel, what we Feel, ſo in the Preſent, if we ſet aſide the Real Forces of the Horſe and the Stone, it is nothing more than to affirm, that the Horſe Draws, when the Stone is Drawn.

The Third Inſtance conſider'd of Motion being Equal in the Change of it, in the mutual Concourſe of Bodies.

§. 47. The Third Inſtance to Juſtify this Law of Action and Re-action being Equal, is, that of Motion being Equal in the Change of it in Bodies, in their Mutual Concourſe, according to §. 44. whereas in any Material Beings, we can mention, it is not certain, and is far from being Prov'd by any Experience, that they obſerve this Law; It is not obſerv'd in the Concourſe of Fluids and Solids, as in Water and Marble, not in Fluids with Fluids, as in Fire and Water, nor yet in Solids compar'd with Solids, as in Steel with Lead, or Wood with Stone; If we will allow theſe ſeveral Bodies to have any Diſtinct and Peculiar Forces of their own.

Sir Iſ. Newt. Optic. Query 31. towards the End.

And from hence it is, that the Quantity of Motion is not always the ſame, betwixt Two Bodies in their Mutual Concourſe, but Motion may be got or loſt, and is more apt to be loſt than got, and is always upon the decay; for Bodies, which are either abſolutely Hard, or ſo Soft, as to be void of Elaſticity, will not Rebound from one another; if the Pendulums be of Lead or Soft Clay, they will loſe all, or almoſt all, their Motions, if of Elaſtick Bodies, they will loſe all, but what they recover from their Elaſticity.

The Doctrine of Expanſive and Contractive Forces, which I have Affirm'd, gives an Account of this Phænomenon, which is here propos'd from Experience and Obſervation, that Motion is more apt to be loſt than got, and is always upon the Decay, (which will not be ſolv'd by the Inertia of Matter or by Gravitation,) becauſe, as the Expanſive Force in Bodies is much leſs than the Contractive, the Latter will be continually prevailing againſt the Former, and the Elaſtick Bodies will loſe all their Motion, but what they Recover from their Elaſticity, that is, from their Expanſive.

Matter ſuppos'd to conſiſt of nothing but Bulk or Magnitude, which is abſurd.

§. 48. If Matter is an Abſtracted Subſtance, which only conſiſts of Bulk or Magnitude, and ſerves by the Parts, of which it is made up, to Number the ſeveral Velocities, or to give the Sum of them in each Motion, it is the ſame as to ſay, that if 5 Velocities, for Inſtance, are carry'd againſt 1 Velocity, which is Five Times Greater than one of the Former, they will be Equal in their Moments, and whatever Change is made by ſuch a Concourſe, it will be Equal in both the Bodies, which Concurr, computing $\frac{1}{5}$th of the Greater Velocity to be anſwerable to 1 of the Leſſer, which, if true, yet ſuppoſes Matter to be nothing but Bulk and Magnitude, which is a falſe and a wrong Notion of it.

Five Velocities not Equal to one Velocity which is Five Times Greater, which this Doctrine ſuppoſes.

§. 49. On the Contrary, that $\frac{1}{5}$th of a Greater Velocity is Equal to 1 Velocity of a different Kind, we have already ſhewn there is ſome Reaſon to Conteſt, which we ſhall here farther Exemplify in the Caſe of Sounds; where ſuppoſing by one Kind of Vibration a Baſe Sound to be produc'd, and by another, that is 5 Times Quicker, a Treble, and the String of the Harp in the Former to be 5 Times Groſſer than that of the Latter; can any one Imagine, that $\frac{1}{5}$th of the Vibration of a Treble will be Equal to 1 of the Baſe, or, if the Treble deſcribes never ſo ſmall a Vibration, and the Baſe never ſo large, that the Velocity or the Sound of the one, will ever be made Equal to that of the other? It ſeems to be Impoſſible, and in General it is abſurd to believe, that 1 Velocity, which is Perform'd in 1 Time, can be Equal to $\frac{1}{5}$th of another Velocity, which Velocity is Perform'd in the ſame Time, unleſs 1 is Equal to $\frac{1}{5}$th: The Caſe therefore is this, that a Force or Velocity, Exerting it ſelf in a Point or a Line, may be 5 Times Greater than another, and will not be Reducible to it, nor will be Equal to the Sum of 5 Forces, each of which are 5 Times leſs, becauſe a Force or Velocity, which is Greater than any one of them, will be likewiſe Greater than all their Velocities put together in their Real Force or Velocity; Thus alſo Fire by the ſame Force, that it ſubdues one Quantity of Force againſt it, is ſufficient to overcome Two, Three, or a Hundred Times of the ſame kind of Force Acting againſt it, and tho' Spaces, deſcrib'd by Bodies which Move, are, according to Mechanicks, compounded of the Times and the Celerities of their Deſcription, and 1 Time into 5 Degrees of Celerity is Equal to 5 Times into 1 Degree of Celerity in the Production of Lines Equal in Length, yet the Intrinſick Value of thoſe Lines will not be Equal, the one being deſcrib'd by a 5 Times Greater Celerity than the other.

Equal Changes of Motion not prov'd upon any Suppoſition.

§. 50. But, that the Changes of Motion are Equal in both Bodies, is leſs Explain'd; for, as in the former Section, if the Velocities are Unequal in the Bodies or Magnitudes, which we will now ſuppoſe Equal, ſince a Unit in one Velocity is not Equal to a Unit in another, and ſince, by what has been ſaid, they are not really Reducible to each other, it will follow, that, upon their Mutual Concourſe, the Changes in each cannot be Equal; if the Velocities are Equal, and the Magnitudes, by which their Sums are Computed, are ſo too, Two Equal Forces, in their contrary Action, will produce Nothing, or, which is the ſame, a Mutual Deſtruction of each other, and therefore there will be no Equal Changes of Motion; if the Magnitudes are Unequal, and the Velocities the ſame in their Degree or their Force, 5 Equal Velocities will be Superior to 1 by 4, and therefore there will not be an Equal Change in the Motions, but 1 will be deſtroy'd and the other 4 proceed without Oppoſition, in all which here is nothing of Action and Re-action, but a Mutual Oppoſition of Forces and no Equal Change of Motion.

If any Thing more is conſider'd than Velocity either Equal or Unequal, and Magnitude or the Sums of ſuch Velocities, that is, if Reſiſtance or Elaſticity, or any other Quality in Matter is, we muſt have Recourſe to the 47th Section, to anſwer the Proof of this Law of Action and Re-action, ſince it is plain from thence, it does not obtain, where Matter is taken in Groſs, and with all it's Qualities; and by the 48, 49, 50, it is as Evident, that it does not, where taken in the moſt Abſtracted Senſe we can Propoſe, Solidity, by Part the firſt of this Philoſophy, being only an Excluſion of one Portion of Matter out of that Space, which another Poſſeſſes, which is alſo ſuppos'd in Magnitude.

We have hitherto endeavour'd to ſhew, that the Real and Abſolute Re-action of Bodies is not always Equal to the Action of them, and if they are not in their Real and Abſolute Forces, they are only ſo in Abſtraction, which therefore is nothing elſe than a Creature and a Chimæra of the Mind. We muſt likewiſe add, that in the Real Forces of Bodies, as Re-action is not always Equal to Action, ſo that neither are they always Contrary; for the Expanſive Force Acts with the Expanſive, and the Contractive with the Contractive, Fire promotes the Expanſive Force of Bodies, which are Inflammable, and Lead the Contractive of Bodies, which are Heavy, by being Laid upon them, and yet neither the one nor the other are Imagin'd to Loſe as much Force, as they Communicate, but Increaſe it in other Bodies, whilſt they Retain it in their own.

This Law not prov'd from Attractions.
Mr Whiſton's Phyſ. Math. Prælect. 5. Art. 5.

§. 51. As for this Law Obtaining in Attractions, Attraction is the very Property in Matter to be Prov'd from it, and therefore to alledge it as an Inſtance for the Proof of that Law, by which it ſelf is to be Prov'd, as it is not done by the Great and Learned Author of the Preſent Philoſophy Sir *Iſ. Newton*, ſo it is no diſtinguiſhing Mark of the Judgment or Penetration of thoſe, who wou'd ſeem to ſupply the ſuppos'd Deficiency of the Perſon they undertake to Explain; we ſhall not therefore enter into the Reaſoning made uſe of by them in Reference to this Phænomenon, which at the beſt depends upon Law the Firſt, and which has been already conſider'd, but proceed to the Experiment, produc'd from the aforeſaid Author, of the Load-ſtone and Iron, which being plac'd in Veſſels peculiar to each, fill'd with Water and touching one another, floated on the Stagnating Fluid, neither of them Propelling the other, but by the Equality of their Attraction kept in and reſtrain'd their Mutual Endeavours to unite, and at length being reduc'd to a perfect Æquilibrium they became Abſolutely Quieſcent.

This Law not prov'd from the Experiment of the Load-ſtone and Iron.

§. 52. But if the Iron and Load-ſtone, plac'd in Water, are in an Æquilibrium, and therefore their Mutual Actions upon each other Equal, when the ſame Bodies are plac'd in Air and come together by their Mutual Actions, thoſe Actions for the ſame Reaſon cannot be Equal; But why a Law of Action and Re-action, and of Nature in General, ſhou'd be formed upon theſe Bodies plac'd in Water, rather than in Air, will be Impoſſible to determine, ſince they are only both of them particular Phænomenons of it, which Reſult from different Circumſtances of the ſame Bodies, and conſequently have neither of them a Right in Preference to the other, to Preſcribe to the Actions of all Nature, no more, than, becauſe Fire Burns in Air, and is Extinguiſh'd in Water, we have therefore juſt Reaſon to Conclude, that the proper Nature of Fire is not to Burn, but to be Extinguiſh'd; It were eaſy to ſhew the Fallacy of Reaſoning from this Experiment more particularly, but we have not Time at Preſent to Enlarge, unleſs to take notice, that both this Experiment, and another, which is Analogous to it, only prove, that the Iron and the Load-ſtone have, each of them, Diſtinct Forces of Action belonging to them, by which they in ſome Caſes Attract each other, and in ſome become Quieſcent, but do not Evidence, that the one is only a Re-action upon the other, Reſulting from the Action of the Former; Thus Fire and Water have Peculiar Forces appertaining to them, and it is not neceſſary, that Water ſhou'd Re-act in the ſame Proportion as Fire Acts, in the Application of the one to the other, only, that Water ſhou'd obtain it's Proper Force, which is independent of the Fire, and Reſiſt or Submit to it, as the Proportion of Action is betwixt them; which Actions, and the Proportion or Quantity of them, it is the Buſineſs of Philoſophy to Enquire into, and Aſcertain.

Dr. Keill's Intr. ad Ver. Phyſ. Lect. 12. Lex. 3. Art. 5.

CHAP. II.

Concerning the Mutual Concourſe of Bodies, and the Laws Relating thereto, as alſo of the Compoſition of Forces.

The Firſt Law concerning the Mutual Concourſe of Unelaſtick Bodies. Mr. Whiſton's Phyſ. Math. Prælect. 5. Art. 6.

§. 1. AFTER Examining into the General Laws of Nature, we are to Inquire into thoſe, which concern the Motion of Bodies in their Mutual Concourſe; the Firſt of which is, that of Two Equal Bodies, which are wholly void of Elaſticity, If the one is mov'd and carry'd againſt the other, which is perfectly Quieſcent, in the Occurſe they will proceed together to the ſame Side and in the ſame Direction, each with half the Velocity of the Body, which is mov'd; becauſe the Body, which is in Motion, will Impell and Accelerate the other, till it can do it no farther, that is, when the Motion of the Quieſcent becomes Equal to that of the Moving Body, and conſequently, when the whole Motion is divided between them both.

Objection the Firſt againſt this Law.

§. 2. Against which there will be this Objection, That Matter, as before, is ſuppos'd to be an Abſtracted Subſtance, without any Property, excepting it's Magnitude, and Preſerving inviolably it's own Dimenſions, and in that Senſe only, Solid or Impenetrable, it is not Hard nor Reſiſting, but merely Paſſive, that is, has no other Action, but the Motion Impreſs'd; This therefore, in the Real Actions of Bodies one amongſt another, is far from being a Law of Nature, ſuch a Law will neither account for the Motion in the Concourſe of Equal Quantities, of Fire and Water, of Oil of Vitriol and Tartar, of Marble with Lead, or common Wood with Clay, or any other Bodies, even of the ſame Kind, as Fire with Fire, or Lead with Lead, *&c.*

Objection the Second againſt this Law.

§. 3. It is not much more happy in proving it's Truth, even upon the Suppoſition of the Preſent Abſtraction; for if a Magnitude is endu'd with a certain Force of Velocity, and is carry'd againſt an Equal Magnitude, which is Quieſcent, that is, where no Powers or Faculties of Matter are conſider'd on either Hand, and no ways Interfere with this Velocity and Quieſcence, the Abſtraction will be the ſame, as if we ſuppos'd 1 Velocity Acting againſt 1 Inertia; but if 1 Velocity can excite 1 Inertia into $\frac{1}{2}$ a Velocity, there is the ſame Reaſon it ſhou'd excite it into 1 Velocity, and by conſequence expend it's whole Force upon it, and become it ſelf 1 Inertia; unleſs an Inertia is more Capable of being Excited out of it's Inertia than an Inertia, which already is Excited, is Capable of being more Excited out of it's Inertia.

§. 4. MOREOVER, how a Mere Velocity can Act upon a Mere Inertia, or one Abſtracted Magnitude or Quantity upon another, any more than Action upon no Action, or a Mathematick Figure upon a Mathematick Figure, or Space upon Space in the Abſtract, is as yet Unexplain'd, to which and no more the Preſent Law Amounts.

Objection the Third againſt this Law.

§. 5. LASTLY, if Re-action is not Equal to Action, it will be Impoſſible, that 1 Velocity ſhou'd not move 1 Inertia with the ſame Velocity, which it brings, without loſing any of it's own; that is, if there is no Return or Repulſe of the Inertia upon the Velocity, it will preſerve it's own Force, and carry on the Inertia with the ſame; but if Re-action is Equal to Action, that Re-action ſhou'd ſubſiſt or be Imagin'd to be in an Inertia, or Non-action, is altogether Abſurd and a direct Contradiction. If therefore this is not a Law of Real Matter according to §. 2, nor of Abſtracted Matter according to the following Sections, of what Matter it is a Law, will be difficult to Affirm; This certainly muſt be ſaid, that what is the Real Reſult from the Concourſe of Bodies can be no otherwiſe determin'd, than from knowing the Peculiar Forces of ſuch Concurring Bodies, which the Preſent Philoſophy ſeems to be little Acquainted with.

Objection the Fourth againſt this Law.

§. 6. A Second Law in Relation to the Mutual Concourſe of Unelaſtick Bodies is, that if Two ſuch Bodies, which are Equal, are carry'd againſt each other with the ſame Velocity, after their Colliſion they will be both Quieſcent, for the ſame Reaſon, that $+a-a$ in the Literal Arithmetick is Equal to 0; For where one Force or Quantity Affirms it ſelf, and another is Negative of it, the Reſult muſt be the Deſtruction or Annihilation of both: It is plain, Oppoſite and Equal Forces will be in an Equal Balance, and ſince neither of them can poſſibly Prevail a Quieſcence muſt ſucceed.

The Second Law concerning the Mutual Concourſe of Unelaſtick Bodies. Mr. Whiſton Phyſico-Math. Prælect. 5. Art. 7.

§. 7. THIS therefore is an Axiom, that Two Equal Forces, Acting in oppoſite Directions, will produce nothing in Reſpect of ſuch Forces, becauſe they Deſtroy each other, that is, their Mutual Progreſs will be abſolutely Hindred; But how, or which way, is ſuch an Axiom a Law of Nature, any more than, 2 Subſtracted from 2 leaving Nothing, is a Law of it? Will Either of theſe Axioms Aſſiſt us in the Laws of Motion, betwixt the Parts of Flame, of a Fluid, or any other Body whatſoever, or betwixt a Fluid and a Solid, or betwixt a Solid and a Solid? We may as juſtly ſay, that, becauſe $2+2$ is Equal to 4, or $2-2$ is Equal to 0, therefore the Fire Burns, or Nature Acts, in all Reſpects, Agreeably to what we Obſerve in the ſeveral Circumſtances of it.

Objection the Firſt againſt this Law.

§. 8. BUT which is more, tho' one Force, Acting againſt another, Produces no Progreſſive Force on either Hands, yet how will this be Reconciled with the Law of Action and Re-action, where the Change of Motion is Equal, ſince, in the Preſent Caſe, there is no Motion at all? For it ſeems to be plain, that if one abſolute Action *A*, carry'd againſt another abſolute Action *B*, is Equal, according to the Law which we now conſider, the ſame abſolute Action *A* cannot be Equal to the Re-action of *B*; becauſe *B* is only Equal to *A*, when it is carry'd with a Poſitive Force againſt it, and therefore cannot be Equal to it by a mere Re-action only, that is, when it is Quieſcent, and is not carry'd with ſuch a Force againſt it.

Objection the Second againſt this Law.

§. 9. BESIDES, as this Law of Motion, in the Concourſe of Bodies, little Agrees with the Fundamental one of Action and Re-action, ſo does it as little with the Firſt, juſt now mention'd; For if a Velocity, Acting upon an Inertia, gives that Inertia half of it's own Action, one Velocity with one Inertia Acting upon another Velocity, which is contrary to it, with the ſame Inertia, ſhou'd cauſe $\frac{1}{2}$ a Velocity on contrary Sides or Directions; For if one Velocity, on one Hand, will give an Inertia $\frac{1}{2}$ its Velocity, the other Velocity, on the other Hand, will give the contrary Inertia $\frac{1}{2}$ of it's Velocity, and the Remainder of the Velocities, on both Hands, will be in an Æquilibrium; Whereas, according to this preſent Law, the whole of the Velocities will be Mutually transfer'd to each other, and from thence will ariſe a Deſtruction of both.

Objection the Third againſt this Law.

§. 10. THE Third Law is, that if Two Unequal Bodies, which are not Elaſtick, ſhou'd meet each other with ſuch a Velocity, that as much as the one Body exceeds the other in Magnitude, ſo much the other ſhou'd exceed the Former in Velocity,

The Third Law of Unelaſtick Bodies.

Mr. Whiſton. Prælect. 5. Art. 8.

or, which is the ſame, if the Velocities are Reciprocal to the Bodies, after their Mutual Concourſe ſuch Bodies will be Quieſcent; Becauſe the Quantities of Motion will be on both Sides Equal, and being Contrary will Deſtroy each other.

This Law already anſwer'd in the foregoing Sections.

§. 11. THE Foundations of this Law have been already Examin'd and Conſider'd, and Firſt in Reſpect of Equal Quantities of Motion, being calculated by making Five Degrees of Velocity, for Inſtance, Equal to the Sum of Five Equal Velocities, which this Law ſuppoſes, and is not prov'd. Second, in Reſpect of Equal Forces deſtroying each other, which is an Axiom, but of little Service to the Explaining of Nature, according to what has been alledg'd in the foregoing Sections.

The Fourth Law of Unelaſtick Bodies Conſider'd. Mr. Whiſton. Prælect. 5. Art. 9.

§. 12. THE Fourth Law concerning Unelaſtick Bodies is, that if a Body, which is mov'd, is carry'd againſt another, which is Quieſcent, however Unequal in their Bulk or their Quantity of Matter, both of them after their Colliſion will proceed with a Common Velocity to the ſame Parts, as in Law the Firſt, and the Common Velocity will be ſo much Diminiſh'd, as both the Bodies taken together are Greater than the Body, which was originally mov'd. Thus, if *AB* is mov'd againſt *C*, which is Quieſcent, with a Certain Velocity, that is, Two Particles of Matter againſt one, the whole Velocity, which appertain'd to *AB*, will after Colliſion be diſtributed and divided into the whole Maſs *ABC*, and therefore, ſince the Moments muſt be the ſame, as before Colliſion, the whole Velocity muſt be Diminiſh'd in Proportion, as the whole Maſs is Increas'd.

FROM whence it is Evident, that this Law depends upon the Truth of the Firſt, which has been already Examin'd, and therefore the Preſent does not want any particular Confutation here; unleſs we farther add, that even upon the Suppoſition of the Truth of that Law, if *A* one Particle of Matter is carry'd againſt *C*, it communicates $\frac{1}{2}$ it's Velocity to it, and ſo it muſt be ſaid of *B*, another Particle of it; how therefore, when they are mov'd together againſt *C*, they ſhou'd ſtop, before they have each of them communicated $\frac{1}{2}$ their Velocity to it, is no otherwiſe to be Explain'd, but by Curbing and Reſtraining the Communication of Velocity at Pleaſure, in order to make the whole *ABC* to Proceed with one and the ſame Celerity; which therefore ſhou'd have been Prov'd, namely, that the Quieſcent Body can never have a Greater Force Impreſs'd upon it from the Action of Two Bodies, or Particles of Matter *A* and *B*, than from that of one as *A*; If it can, ſince, in the Action of *A* upon *C*, they are ſuppos'd to proceed together, in the Action of *A* and *B* upon *C*, they will not, but *C* will proceed with a Greater Velocity than *AB*; that is, if *A* communicates $\frac{1}{2}$ it's Velocity to the Quieſcent Body *C*, *B* will likewiſe do it, from whence *C* will have 1 Velocity, whilſt *A* and *B* Retain only 1 betwixt them, that is, *C* will be carry'd with a Greater Velocity than *AB*, and therefore not with a Common one to Both.

The Fifth Law of Unelaſtick Bodies Conſider'd. Mr. Whiſton. Prælect. 5. Art. 10.

§. 13. THE Fifth Law is, that if Two Unelaſtick Bodies, which are Unequal, are mov'd with an Equal Velocity againſt each other, the Quantity of Motion in both, after Colliſion, will be the Difference of their Motions, before their Mutual Concourſe; becauſe, if *AB* and *C* are carry'd againſt each other, the Equal Moments of both will be deſtroy'd, and there will only Remain the Difference of them, which is to be Impended or Spent upon the whole Maſs, *ABC*; in which Law, Firſt, the Mutual Deſtruction of Equal Moments is not accounted for, by what foregoes; nor Second, according to the laſt Section, the whole Maſs proceeding with one and the ſame Velocity after Colliſion; and in Reality, this Philoſophy of the Mutual Concourſe of Bodies is no more, than Moving *AB* and *C* backwards and forwards with a Uniform Velocity, juſt as we pleaſe, and taking it for granted, that after Colliſion *AB* and *C* muſt certainly, one way or other, move together.

The Sixth Law of Unelaſtick Bodies. Mr. Whiſton. Prælect. 5. Art. 11.

§. 14. THE Sixth Law is, that if Two Unelaſtick Bodies, being Equal, are mov'd with an Unequal Velocity to the ſame Side, after their Colliſion the Quantity or Sum of Motion will continue the ſame, but the Common Velocity will be the half of the Velocity of both taken together; Thus, if *A* or *B* moves with 4 Velocity, and *C* with 2 towards the ſame Side, after *A* or *B* arrives at *C*, they will both proceed with 3 Velocity each, ſo as to make the Sum of Motion the ſame with the Former, and the Common Velocity the half of the whole Motion.

Objection the Firſt againſt this Law.

§. 15. This Law therefore, and the Explanation of it, is as Inconceivable as the Former; ſince, if *A* or *B*, when carry'd againſt *C* conſider'd as Quieſcent, ſpends $\frac{1}{2}$ it's Velocity upon it, according to Law the Firſt, why it ſhou'd communicate none to it, if the Velocities are Equal, and *C* is in Motion, is altogether Inexplicable; But this it muſt not do, if the Preſent Doctrine is True, becauſe after Colliſion they are to obtain one Common Velocity, that is, *A* or *B* and *C* are to have one Common Velocity, which is 2 after Colliſion, therefore *A* or *B* communicates no Velocity to *C*, tho' in Motion, and yet, by Law the Firſt, it wou'd Impart $\frac{1}{2}$ of it's Velocity to it, if it were Quieſcent, which is Abſurd: Or we may put it in this Way, *A* or *B*, by Law the Firſt, will Impart $\frac{1}{2}$ it's Velocity to *C*, if it were Quieſcent, therefore an Unequal Velocity, = to Two Equal Velocities of *A* and *B*, will, according to that Law, communicate $\frac{1}{2}$ of the Velocity of *A*, and $\frac{1}{2}$ of the Velocity of *B* to *C*, when Quieſcent, that is, 2 Velocity, whereas, according to the Preſent Law, it will have only 1 Velocity communicated to it, when in Motion, which is alſo Abſurd.

Objection the Second againſt this Law.

§. 16. Another Objection againſt this Law is, that, whereas *A* is ſuppos'd to have an Unequal Velocity with *C*, yet, when they come together, they have the ſame Velocity, if *A* or *B* has 4, and *C* has 2, it ſeems, by an amicable Compoſition of the Matter, they will each of them proceed with the Velocity of 3; On the Contrary, if the Degrees of Velocity are Really Different, ſo that one is twice as Swift as the other, or as 4 to 2, it will be Impoſſible to ſay, how, upon their Meeting, they ſhou'd obtain the ſame Velocity, according to the Preſent Law; for if a Swifter Velocity, as of *A* or *B*, is Reſtrain'd by a Slower, as of *C*, it ſo far deſtroys that Velocity, and therefore their Sums cannot be the ſame before, as after their Colliſion, which is affirm'd; if the Degrees of Velocity are not Different, but Equal, that is, if the Velocity of one Body, is not Swifter than that of the other, and *A* or *B* has only the Sum of 4 Velocities, each of which is Equal to one of thoſe, of which *C* has 2, there will be different Sums of Velocities, where the Sums or Quantities of Matter are Equal, by which the Sums of the Velocities are Computed; which is again Impoſſible.

The Seventh and Laſt Law of Unelaſtick Bodies Conſider'd.
Mr. Whiſton's Prælect. 5. Art. 12.

§. 17. The laſt Law of Unelaſtick Bodies is, that, if of Two Unequal ones, which are moved the ſame Way, the Greater Impinges upon the Leſs, the Common Velocity after Colliſion will be Greater than half of the Sum of the Velocities; On the Contrary, if the Leſs overtakes the Greater, the Common Velocity will be Leſs after Colliſion, than that half of the Sum of the afore-mentioned Velocities. For Example, if *AB* has 6 Velocities, and *C* has 2, the Common Velocity after Colliſion will be more than 4; becauſe, by the preceding Law, if the Bodies were Equal, *A* and *C* wou'd proceed together with the Common Velocity of 4, but *AB* being Greater than *A*, and conſequently than *C*, it will ſpend more of it's Velocity upon *C*, than *A* did, before they come to an Æquilibrium, and therefore the Common Velocity, with which *ABC* proceeds, will be Greater than 4; and for a Contrary Reaſon, if *C* incurrs upon *AB*, the Common Velocity will be Leſs than 4.

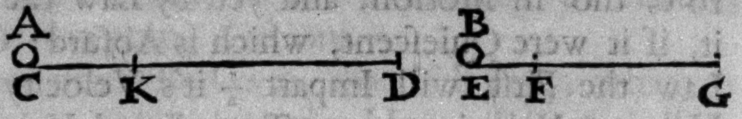
This Law therefore is Examin'd in the Former, and does not require any farther Arguments, or Convictions of it's Uncertainty or Falſhood. The Solution of all this Buſineſs is, that Bodies, which have a Contractive Force Unite, and Adhere to each other by that Force, or Move together, upon their Velocities, which are of an Expanſive one, Deſtroying their Particular Contractive Forces or Gravitation to the Earth.

Two Theorems in Relation to the Impaction or Colliſion of Bodies Demonſtrated.
Sir Iſ. Newt. Princip. Leg. Coroll. 3.
Dr. Keill's Introd. ad Ver. Phyſ. Theorem 18. & 19. Lect. 12.

§. 18. But, before I leave this Subject of the Impaction and Concourſe of Bodies, I ſhall ſubjoin the following Theorem from a Celebrated Philoſopher; That the Quantity of Motion, which is computed by taking the Sum of the Motions, which are carried to the ſame Side, or the Difference of them carry'd to Contrary ones, is not Chang'd by the Action of Bodies amongſt one another. Which Theorem has Furniſh'd an Occaſion to another Excellent and Ingenious Philoſopher, in the Preſent Mechanicks, to Form the Two Subſequent ones, of which I ſhall Give the following Demonſtrations.

Theorem the Firſt is, If one Body Impinges upon Another, which is Quieſcent, or which is Moved Slower to the ſame Side, or in the ſame Direction, the Sum of the Motions in both Bodies, to the ſame Side, will remain the ſame after their Impaction or Colliſion, as before; Let the Body *A* be moved according to the Direction of *CD*, from *C* to *D*, and let it Impinge or Fall upon another Body *B*, which is ſuppos'd either to be Quieſcent, or to be moved more ſlowly in the ſame Direction; It is Affirm'd, that the Sum of the Motions in both Bodies towards the ſame Side, that is, from *C* to *D*, will, before and after their Impulſe, Impaction, or Colliſion, Remain the ſame.

Let therefore *CD*, the Motion of the Body *A*, be $=a$, *EF*, the Motion of the Body *B* to the ſame Side, be $=b$, the Sum of their Motions will conſequently be $CD+EF=a+b$; Let *FG* repreſent the Motion, which is Impreſs'd from *A* on *B*, which we will ſuppoſe $=c$; Since therefore Action and Re-action are Equal and Contrary, *B* by Re-acting upon *A* will take ſo much from *A*, as is Imparted to it; therefore let *KD* be Equal to $FG=c$, and the Motion of *A* after the Impaction will be $=a-c$, and the Motion of $B=b+c$, but $a-c+b+c=a+b$, the Sum of their Motion before ſuch Impaction.



Corol. 1. If $FG=CD$, or $c=a$, *C* and *K* will Coincide, and $CK=a-c=0$, and *A* after Impaction will remain Quieſcent, and *B* will proceed with the Motion of $b+c$; that is, if $a-c=0$, $b+c$ after Impaction $=a+b$, or the Sum of their Motions before it.

Corol. 2. If *FG* is Greater than *CD*, the Point *K* will fall to the Left Hand of *C*, and the Motion of *A* will be Negative, or to a contrary Side; that is, if *c* is Greater than *a*, let *d* be the Difference, therefore $a=c-d$, and the Sum of their Motions after Impaction will be $=c-d-c+b+c=-d+b+c$, that is, $-d$ will belong to *A*, which will be therefore Negative, and $b+c$ to *B*; and $-d+b+c=a+b$, becauſe $c-d=a$.

Theorem the Second is, If Two Bodies Move to Contrary Sides, and Meet Each other, the Sum of their Motions to the ſame Side, which is the Difference of their Motions to Contrary Sides, both before and after their Concourſe will Continue the ſame towards the ſame Side.

Let *a* Repreſent the Motion of *A*, and $-b$ the Motion of *B* to a Contrary Side, the Sum of their Motions to the ſame Side, which is the Difference of their Motions to Contrary Sides, will be $a-b$, let *c* farther be $=$ to the Motion communicated to the ſame Side; therefore $a-c=$ to the Motion of *A* after their Concourſe, and the Motion of *B* after it will be $-b+c$; but $a-c-b+c$ after Concourſe $=a-b$ the Motion of theſe Bodies before it.

Corol. 1. If $b+c=a$, $a-b-c$ the Motion of *A* after Concourſe $=0$, and *A* will be Quieſcent after ſuch Concourſe, and *c* the Motion of *B* after Concourſe $=a-b$ the Sum of both their Motions to the ſame Side, or the Difference of them to Contrary ones.

Corol. 2. If $b+c$ is Greater than *a*, and *d* is the Difference, then $b+c=a+d$, and $b+c-a=d$, and $a-b-c=-d$; that is, $a-b-c$, the Motion of *A* after Concourſe, will be Negative, and to a Contrary Side, and the Motion of *B* will be $+c$, but $-d+c=a-b-c+c$, the Motion of the Bodies after Concourſe, $=a-b$, the Motion of them before it.

The foregoing Theorems and the Demonſtration of Them, Inquir'd into.

§. 19. In Reſpect therefore of theſe Two Theorems, whatever we have alledg'd againſt Action and Re-action being Equal and Contrary, as alſo concerning the Communication of Motion, and Matter being conſidered only as Conſiſting of mere Bulk and Magnitude, is Equally Valid here; And particularly, *c* is ſuppoſed to be the Motion communicated to *B*, and loſt to *A*, if ſo, it is manifeſt, that the Quantity of Motion after Contact, or Impaction, or Impulſe will be the ſame as before it; But how is this Prov'd, that *c* is Loſt to *A* and Gain'd to *B*? Not from the Nature of Matter, which is ſuppos'd to have nothing, but Bulk or Magnitude, which can neither Act or Re-act; If it is ſaid this Force of Re-action is ſuppos'd, then that very Thing is ſuppos'd, which is to be Prov'd; and the foregoing Theorem, which is Reſolv'd into the Two Succeeding ones, is Demonſtrated by Preſuming that to be True, which it propos'd to Evince to be ſo; that is, $a+b=a-c+b+c$, becauſe *a* Loſt *c* and *b* Gain'd it, and *a* Loſt *c* and *b* Gain'd it, becauſe they are ſuppos'd to do it. If there is any Real Force in Matter, by which this is Prov'd, it ſhould be ſhewn us, and how it is deriv'd from mere Bulk and Magnitude, and how it is a Conſtant and Unvary'd

Force in all Material Beings, in Bodies Elaſtick and Unelaſtick, in Fire, Water, Wood, Stone, Metals, and Minerals; for till then, as we have before ſaid, we can conclude it to be no other than a Creature of the Mind, and a Force, which Reſts in the Imagination, without Reſiding in any Part of Nature; and yet, which is ſomething Wonderful, this Property or Theorem of Motion is brought to Prove Action and Re-action to be Equal and Contrary, which Theorem is notwithſtanding Prov'd from ſuppoſing Action and Re-action Equal and Contrary; On the other Hand, we ſhall in this Chapter Give the Laws of the Mutual Congreſs of Bodies from Real Forces in Nature, the Expanſive and Contractive.

Elaſtick Bodies Conſider'd, and the Firſt and Primary Law of Them Explain'd.
Mr. Whiſton. Prælect. 5. Art. 13.

§. 20. After the Laws of Unelaſtick Bodies follow thoſe of Elaſtick, that is, of Bodies, which Reſtore themſelves with the ſame Force, with which they are Compreſs'd; The Firſt is, That in Bodies perfectly Elaſtick and Equal, if the one is Mov'd againſt the other, which is Quieſcent, upon their Impaction that, which is Mov'd, will be Quieſcent, and the Quieſcent will Proceed with the ſame Celerity, which was originally in the Impellent: Becauſe, by the firſt Law of Unelaſtick Bodies, or of Mere Impulſe, it will communicate half it's Celerity, but the Elaſtick Force is Equal to that Celerity, which upon Impulſe the one Body Gains, and the other Loſes, and Acts Contrary ways, ſo as to be Added to the Motion of the Body Impell'd, and Subſtracted from the Impellent; from whence it will follow, that ſince half is Communicated by Simple Impulſe, and the other half by the Elaſtick Force, the whole will be Transfer'd from the Impellent to the Body Impell'd, and the Former will remain Quieſcent, ſeeing the firſt half is loſt by Communication, and the laſt by Re-action; Thus, if *A* is 4 Velocity, and *B* 0 Velocity, after Impulſe *A* is 2, and *B* 2, and the Elaſticity Adds 2 more to *B*, and Gives 2 leſs to *A*, ſo that, in the Reſult, *A* will be 0, and *B* 4 in Velocity.

Objection the Firſt againſt this Primary Law of Elaſticity.

§. 21. Against this Doctrine and Hypotheſis we are therefore Firſt to Obſerve, that That of Simple Impulſe is neceſſary to This, which has been Conſider'd, and which, if not true, Involves the Preſent in the ſame Error; Second, That, tho' this Law of Elaſticity, and the others, which depend upon it, were certain, and did obtain in Nature, they are yet far from being any General Laws of it, ſince Heat and Cold, Hardneſs and Fluidity, *&c.* are not Reducible to them.

Objection the Second againſt this Law.

§. 22. To Omit what we have ſaid in the foregoing Section, the very Hypotheſis of this Kind of Elaſticity (for Simple Impulſe is a ſort of one by it's Action and Re-action) is, in the firſt Place, the moſt Arbitrary, that can be poſſibly Imagin'd, and in the Second, is not Anſwerable to it ſelf: It is Arbitrary, for why the Elaſticity ſhould be 2, in the Inſtance above, rather than 4 or 8, or any other Number, is not determin'd, by which means *A* wou'd be -2 and *B* 6 Velocity, or *A* -6 and *B* 10 Velocity, and Laws might be form'd, and Calculations made, upon ſuch Hypotheſes, as well as that, which is propoſed to us; and ſo on the Contrary, inſtead of 4 and 8 we might likewiſe ſubſtitute 1, or $\frac{1}{2}$, or any Fraction whatſoever, and in the firſt Caſe, *A* wou'd be 1, and *B* 3, and in the Second, *A* wou'd be $1\frac{1}{2}$, and *B* $2\frac{1}{2}$, which wou'd give an abundant Scope to theſe Abſtracted Reaſoners to Compute the Laws and Rules of ſuch a ſuppos'd Elaſticity, whenever They ſhall be at Leiſure.

Objection the Third againſt this Law.

§. 23. That this Proportion or Degree of Elaſticity is farther Arbitrarily aſſum'd, is Evident, ſince to the Nature of Elaſticity it is only required, that the Repreſſure ſhou'd be Equal to the Force, which Compreſſes, which is as well obſerved in $-4+4$, or $-\frac{1}{2}+\frac{1}{2}$, as in $-2+2$, where the Velocities of both Bodies are before ſuppos'd, by Law the firſt, to be Equal; for if one Body Impinges upon another, and after Contact they proceed with the ſame Celerity, any Force ſuperinduc'd of Acting and Re-acting may be Equally call'd an Elaſtick, as that which is Commenſurate to the Force, which one Body Gains, and the other Loſes, in ſimple Impulſe; becauſe there may be ſuch an Innate Elaſtick Force preſum'd in Bodies, which does not depend upon Impulſe.

Objection the Fourth againſt this Law.

§. 24. Besides which, if the Preſſure and Repreſſure of Bodies were to be Meaſured by the Compreſſion Reſulting from Impulſe, what wou'd that be? Not what is here ſuppoſed, the ſame, which one Body Gains by Impulſe and the other Loſes, becauſe it is Impoſſible, that the Celerity Communicated ſhou'd Re-act with the ſame Force, with which it is Progreſſive on the one Hand, or that the Celerity on the other, which remains and is not Communicated, ſhould Act with a Progreſſive Force, which it has loſt by the Preceding Communication; Thus, if *A* is 4, and *B* 0, in their Velocities, and upon Colliſion let *A* be 2, and *B* 2, there is no Reaſon from thence to Affirm, that by Introducing Action and Re-action, *A* ſhall Communicate 2 more of Velocity, becauſe it has loſt 2, or, that *B* ſhall Re-act with the Force of 2, becauſe it has Acquir'd the Force of 2 in Progreſſion; It is farther altogether Unaccountable, how Elaſticity, which conſiſts in Re-action, ſhou'd promote a Propagation of Motion, as will be afterwards Explain'd.

Objection the Fifth againſt this Law.

§. 25. MOREOVER, If this could be Granted, that by Impulſe 2 Velocity was Communicated from *A* to *B*, and by the Elaſtick Force 2 more, ſo that the Whole ſhould be Transfer'd to *B*, yet this will not be eaſily accounted for, why *A* ſhould be Quieſcent, unleſs upon this Suppoſition, that a bare Communication of Motion, and a Re-action againſt it, ſhall have Equal Effects in deſtroying it in the Impellent *A*, which is Impoſſible, unleſs to Communicate is to Re-act, or a mere Tranſlation of it from one Body to another is the ſame, as to Hinder and Reſiſt it's Communication; if therefore 2 Velocity was Communicated by Impulſe from *A* to *B*, and another 2 Velocity from *A* to *B* by Elaſticity, it wou'd not follow, that *A* ſhou'd be Quieſcent; becauſe if Impulſe Communicates 2 Velocity, and is Quieſcent in Reſpect of that Velocity, which it Communicates, if Elaſticity Communicates 2 Velocity, it's Re-action ſhou'd give an Impreſſion upon the Impellent, ſo as to make it Retire with 2 Velocity, or otherwiſe Elaſticity will be the ſame as Simple Impulſe, which yet are here Diſtinguiſh'd; Nor farther is it Evident, that by Simple Impulſe, what Velocity one Body Gains, the other Loſes, becauſe, if one Body Acts upon another, which has no Force of Re-action, it may Impreſs it's own Action upon that other Body without Diminiſhing it ſelf, as in the Caſe of Fire Acting upon Fuel, or Motion Acting upon Non-Reſiſtance in the Abſtract.

Objection the Sixth againſt this Law.

§. 26. ANOTHER Thing, which we muſt obſerve, is, that this Hypotheſis does not Agree with the Definition of an Elaſtick Body, which is ſaid to be ſuch, when the Preſſure and Repreſſure are exactly Equal, which if they were, it would be altogether Impoſſible, that any thing elſe ſhould Reſult from them, but a Perfect Quieſcence in both Forces; for if *A*, Abſtracted from Impulſe, ſhould Preſs upon *B*, and there is a Force of Re-action Equal to that Preſſure, *A* cannot Move *B* forwards, becauſe *B* Preſſes backwards, nor *B* Move *A* backwards, becauſe *A* Preſſes forwards with a Force on both Hands, which is Æquipollent; if it is ſaid, the Force of Repreſſure is ſuppoſed to be ſuch, as can actually Reſtore it ſelf upon any Preſſure made upon it, then Repreſſure is Superior to the Compreſſion, Contrary to the Definition of a Perfect Elaſticity, and would be ſo far from Promoting of Motion forwards, that it would Repell the Incurrent Preſſure to the Oppoſite Side, and give it a Direction that Way.

Objection the Seventh againſt this Law.

§. 27. WE are farther to take Notice, that if Impulſe is made one Part of the Account in the Action of *A* upon *B*, yet even then this Law will not be True; ſince *A* 4 Velocity, and *B* 0 Velocity, if the Elaſticity of *B* is Equal to the whole Impulſe and Elaſticity of *A*, will upon their Congreſs deſtroy each other; if *B* is Equal to the Impulſe only of *A*, it will deſtroy that and leave the Elaſticity of *A* to exert it ſelf with it's Proper Force; if *B* is Equal to the Elaſticity of *A*, *A* and *B* will be in an Æquilibrium in reſpect of their Elaſticity, and conſequently, the Impulſe will not Prevail, which will be ſpent upon Both, if Law the Firſt of Unelaſtick Bodies is true, that is, they will both proceed with the Velocity of 2, Contrary to the preſent Aſſertion of *A* Transferring it's Whole Velocity to *B*; for by Elaſticity I here mean the Expanſive Force, or the Force of Repulſion, and which is the only true Notion of it, as will be afterwards ſhewn.

Objection the Eighth againſt this Law.

§. 28. BESIDES how *A* 4 Velocity ſhou'd transfer, by it's Elaſticity, 2 Velocity to *B*, and deſtroy 2 in the Impellent *A*, is Inconceivable, if Compreſſion and Repreſſure are Equal; becauſe 2 Velocity, Communicated forward from *A*, is not a Force Equal to no Motion or Velocity at all, Impreſs'd from *B*, and therefore, if the Effects are not Equal, the Cauſes cannot be; that is, Preſſure and Repreſſure are not ſo; but there is no Re-action Impreſs'd from *B*, but what is ſuppos'd to Ariſe from *A*, which can be None, becauſe it's Tendency is forwards.

Objection the Ninth againſt this Law.

§. 29. We muſt Add, it is ſtill leſs Anſwerable to the Definition of perfectly Elaſtick Bodies, that, what one Body Gains and the other Loſes by Impulſe, is the Meaſure of this Elaſticity, becauſe in Equal Bodies A may have 4, or 6, or 10 Velocity, when B is Quieſcent; and conſequently, the Meaſure of Elaſticity may be 2, or 3, or 5, or any other Number, whilſt Elaſtick Bodies, conſider'd in their Innate Force of Repulſion or Expanſion, may not be Proportional to ſuch Numbers.

Objection the Tenth againſt this Law.

§. 30. If, what one Body Gains and the other Loſes, was the Meaſure of Elaſticity, it wou'd not yet be Agreeable to the Definition of it's Nature, or of Compreſſion being Equal to Repreſſure; ſince Velocity of Impulſe, and the Communication of it, has no Connection with Acting and Re-acting, unleſs becauſe A, which has 4 Velocity Communicates 2 to B, which has none, therefore A Acts with the Velocity of 2 by it's Elaſtick Force, and B Re-acts with the ſame, betwixt which Two Propoſitions, it is Impoſſible, there ſhould be any Dependence in Reaſon.

Objection the Eleventh againſt this Law.

§. 31. If all this was true, againſt which we have been Diſputing, theſe Laws of Elaſtick Bodies, as well as thoſe others of Unelaſtick, wou'd be far from giving us any juſt Notions of Things, as they Exiſt; for, tho' they were Adapted to the Solution of ſome kind of Material Beings, as of certain Solid Bodies in their Mutual Concourſe, yet, ſince they would not Comprehend all, nor one Millionth Part of them, of what Importance or Significance can ſuch Laws be to the Explaining of Nature, where ſo ſmall a Part of it is conſider'd? For, if theſe Laws could give an Account of the Mutual Congreſs of certain Hard Bodies, which they cannot do, as thoſe of Bowls meeting each other, which are of the ſame Matter and Force, they can ſtill leſs Inform us of the Properties, which Reſult from the Mutual Congreſs of Marble and Lead, of Steel and Marble, or in General of Stone, or Wood, or Metals, and the various Kinds of them in their Concourſe with each other; and if theſe Laws cannot do this, they can ſtill leſs furniſh us with a Solution of Heat or Cold, of Hardneſs or Fluidity, of Coagulation or Chryſtalizing, All which are entirely unaccountable by ſuch Laws as theſe, which therefore are to be Rejected from a True Philoſophy.

Theſe Reaſonings obtain their due Value, when conſider'd only as Mathematick and Abſtracted ones.

§. 32. Notwithstanding, for the ſeveral Reaſons before Alledg'd, we cannot but be of Opinion, that theſe Laws of Elaſtick Bodies do not ſerve us in the Explanation of Nature, we muſt yet confeſs, that the Demonſtrations form'd upon the Preſent Hypotheſis of Simple Impulſe and Elaſticity are ſuch, as ought to give us a Due Value and Eſteem for the Contrivers of them, as they advance our Abſtracted and Mathematick Reaſoning, amongſt whom none appear to have treated this Subject with Greater Clearneſs and Brevity than the Famous Sir *Iſ. Newton*, and my Loving Friend the Reverend and Learned Mr. *Morgan* before-Mention'd.

Sir Iſ. Newt. Algeb. P. 91. Probl. 12.
Mr. Morgan upon Rohault Chap. 11. Part 1.

But having already Conſider'd the Two Principles, upon which theſe Computations depend, I ſhall now Propoſe the Laws of the Mutual Congreſs of Bodies, deriv'd from their Innate Expanſive and Contractive Forces, after having obſerv'd upon the Great Philoſopher and Geometer here Refer'd to, that, when he comes to give us an Account of Bodies, which meet each other, he Tells us, by Changing the Sign of b, the Celerities of A and B after Reflection will be $\frac{aA-aB-2bB}{A+B}$ and $\frac{2aA+bA-bB}{A+B}$, which is Evident, becauſe, when a tends one way, and b another, if the one is Expreſs'd by $+a$, the other will be Expreſs'd by $-b$, and $Aa-x$, and $-Bb+x$ will be the Motion after Concourſe; The Celerities therefore will be $\frac{Aa-x}{A}$, and $\frac{-Bb+x}{B}$; But $\frac{-Bb+x}{B}-\frac{Aa+x}{A}=a+b$, and $-ABa-ABb+Ax+Bx=ABa+ABb$, and $x=\frac{2ABa+2ABb}{A+B}$; Therefore $\frac{Aa}{A}-\frac{2ABa-2ABb}{AA+AB}=\frac{Aa-Ba-2Bb}{A+B}$ = to the Celerity of A; Likewiſe $-\frac{Bb}{B}+\frac{2ABa+2ABb}{AB+BB}=\frac{2Aa+Ab-Bb}{A+B}$ the Celerity of B.

But then, Firſt, when we come to Inſtances and Examples of this Doctrine, Bodies are ſuppoſed, as alſo in the Calculation, to be Homogeneous in their Matter, and the Moments of Them to Conſiſt of Mere Bulk and Celerity, which we

Deny; And Second, ſometimes *A* is Imagin'd to Incurr with a Negative Force, which ſhews it is nothing, but an Abſtracted Reaſoning; Thus, Let *A, a, B, b,* be 3 Bulk, 8 Celerity, 9 Bulk, 2 Celerity, Reſpectively; If *A* and *B* Proceed the ſame Way, the Celerity of *A* after Reflection is $= \frac{aA - aB + 2bB}{A + B} = -1$, that of $B = \frac{2aA - bA + bB}{A + B} = 5$; that is, the Whole Moment of *A* is 3 Bulk × 8 Celerity, of *B*, 9 Bulk × 2 Celerity before Reflection; but *B* = 9 Bulk Acquires 3 Celerity after Reflection, and therefore there muſt have been 9 × 3 Celerity Communicated to it from *A*, which yet had only 8 × 3 Celerity, but how *A* ſhould Communicate 1 × 3 Celerity more than it had, and by that Means Return with the Celerity of − 1, is ſomething Inconceivable, unleſs in ſuch an Abſtracted Reaſoning.

BUT to proceed to the Laws of the Congreſs of Bodies in a Real Philoſophy.

The Laws of the Congreſs of Bodies in a Real Philoſophy and the Theorems of Them, Eſtabliſh'd upon the Doctrine of the Expanſive and Contractive Forces.

§. 33. LET *A* Repreſent the Quantity of Matter, or the Number of it's Parts, in one Body, and *B* the Quantity of Matter, or the Number of it's Parts, in the other; Let *E* and *C* Denote the Expanſive and Contractive Forces in the Former, and *e* and *c* thoſe of the Latter; And let *V* and *v* Expreſs the Velocities in Each.

THEOREM the Firſt; The whole Moment of *A* will be therefore *AECV*, and that of *B*, *Becv*, and if they tend the ſame Way, the whole Moment may be Expreſs'd by *AECV* + *Becv* after Concourſe; in which we ſuppoſe, that *A* and *B* are only the Numerators of the Forces *ECV*, *ecv*, and theſe the Denominators of the Degrees of them; that the Innate Expanſive and Contractive Forces in the ſame Bodies, *E* and *C* in the Firſt, or *e* and *c* in the Laſt, Act contrary to each other, and that, in Different Bodies, *E* Acts to the ſame Part with *c*, and *C* with *e*, but that *E* and *e* the Expanſive Act contrary to each other, as alſo *C* and *c* the Contractive; that likewiſe the Velocities Impreſs'd *V* and *v* in the ſame Bodies Promote and Act with the Expanſive againſt the Contractive, tho' not in the ſame Proportion, as the Expanſive againſt the Contractive, the one being an Expanſive Force and a Stronger deriv'd from the Mind, and the other from Matter only, that is, that *V* Advances and Promotes the Force of *E* againſt *C*, and *v* that of *e* againſt *c*; and laſtly, that in Different Bodies the Velocity of *V* Acts contrary to the Velocity of *v*, by how much the Laſt is ſlower than the Former, and likewiſe *V* Acts with *c* againſt *e*, and *v* with *C* againſt *E*.

THEOREM the Second; If they Act in Contrary Directions, which is the Caſe of the Moment *AECV* − *Becv*, *A* and *B*, as before, are conſidered only, as the Numerators of theſe Forces, which are ſuppos'd to ſubſiſt in every Part of Matter, which they Number; The Innate Expanſive and Contractive Forces in the ſame Bodies, *E* and *C* in the Firſt, or *e* and *c* in the Laſt, Act likewiſe, as before, Contrary to each other, and in Different Bodies *E* Acts to the ſame Part with *c*, and *C* with *e*, but *E* and *e* the Expanſive Act Contrary to each other, as alſo *C* and *c* the Contractive; Farther, the Velocities *V* and *v*, in the ſame Bodies, Promote and Act with the Expanſive againſt the Contractive, tho' not in the ſame Proportion, as the Expanſive againſt the Contractive, and for the Reaſon Alledg'd above, that is, *V* Promotes and Advances the Force of *E* againſt *C*, and *v* that of *e* againſt *c*; and laſtly, in Different Bodies *V* Acts againſt *v* and with *c*, and *v* againſt *V* and with *C*; alſo *V* Acts againſt *e*, and *v* againſt *E*. And in both theſe Theorems + and − are not Marks or Signs of Addition and Subſtraction, but of the Moments Acting the ſame, or contrary Ways.

FROM whence it follows, that theſe Two Theorems only differ in + or −, but that the Acting Forces fall exactly under the ſame Laws, and which, before we proceed, we ſhall Endeavour to Explain.

FIRST, As for *A* and *B*, they being only the Quantities of the Acting Forces, there is no farther Occaſion to ſpeak of them.

SECOND, *E* and *C*, or *e* and *c*, being the Expanſive and Contractive Forces in the ſame Bodies, Act contrary to each other; the Firſt Acting from a Center, or by Repulſion; and the Laſt towards one, or by Contraction.

THIRD, In Different Bodies *E* is Expanſive or Repells the ſame Way from it's Center, as *c* is Contractive or Tends towards it's Center, and *e* is Expanſive or Repells the ſame Way from it's Center, as *C* is Contractive or Tends towards it's Center;

and therefore E Acts with c in another Body, againſt C in it's own, and, *vice verſâ*, e Acts with C in another Body, and againſt c in it's own; Thus likewiſe E the Expanſive or Repulſive Force in one Body Acts Contrary to e the Expanſive in another, they Acting by Expanſion or Repulſion from different Centers; and for the ſame Reaſon, C the Contractive in one Body Acts Counter to c the Contractive in another, becauſe they Tend to Different Centers.

Fourth, The Velocities V and v in the ſame Bodies, V in $ACEV$, and v in $Becv$, Act with E and e againſt C and c, becauſe C and c Tend to a Center, and conſequently to Quieſcence and Reſt, which is oppoſite to Velocity; whereas Velocity has an Expanſive Force, as Tending from the Center of it's Communication, which Center is yet Different from the Center of the Body's Expanſive.

Fifth, The Velocities V and v in different Bodies Act againſt each other, or not at all upon each other; for, if they are Equal, and proceed the ſame Way, there is no Impaction; if they are Superior the one to the other, ſo much as the Difference is betwixt them, ſo far they are Contrary to each other; and, if they Act in Oppoſite Directions, the Caſe is Manifeſt.

Sixth, Laſtly the Velocity V Acts with c, and v with C, in different Bodies; becauſe V Acts with E, and v with e, againſt C and c in the ſame Bodies, by *Art.* 4, and E Acts with c, and e with C, in different Bodies, according to *Art.* 3; Therefore V Acts with c, and v with C, in different Ones; In like Manner, V Acts againſt C, and v againſt c, in the ſame Bodies, by *Art.* 4, but C Acts with e, and c with E, in different Ones, according to *Art.* 3; Therefore V Acts againſt e, and v againſt E, in different Ones.

It muſt be obſerv'd, that $> <$ are Notes, or Signs of Greater or Leſs, in the following Caſes; Being the ſame, which are made uſe of by Dr. *Wallis* in his Limits of Æquations.

The ſeveral Caſes deriv'd from the fore-going Theorems.

§. 34. Let us therefore now ſuppoſe the Quantities of the Forces, or the Numerators of them, A and B, to be Equal, as likewiſe the Velocities, with which they Incurr upon each other, which therefore muſt be the Caſe of the Second Theorem $AECV - Becv$, that is, where theſe Forces are directed to Contrary Sides; Becauſe otherwiſe, having the ſame Velocities, they could not meet, nor would there be any Concourſe or Impaction: And this we at preſent ſuppoſe, that we may Enquire, what the Real Forces of Bodies are.

Why Two Equal and Equally Unelaſtick Bodies, Carry'd againſt each other with Equal Velocities, will upon their Concourſe be Quieſcent.

Caſ. 1. If $E=C$, and $e=c$, in the ſame Bodies, and $E=e$, and $C=c$, in different Ones; that is, if the Expanſive is Equal to the Contractive in the ſame Body, and the Expanſive is Equal to the Expanſive, and the Contractive to the Contractive in different Ones, and the Sums or Quantities of the Forces, and the Velocities in both, are the ſame, a perfect Quieſcence will follow in both Bodies upon their Mutual Concourſe; Becauſe, in the ſame Bodies, the Expanſive and Contractive Forces are in an Equal Balance, being Equal in their Forces, and Acting Contrary to each other; and in different Ones, E, which Propells one Way, is $=$ to e, which Propells another, and C, which Contracts one Way, and Acts with e, is $=c$, which Contracts another, and Acts with E: And this may poſſibly be the Caſe of Two Globes of Lead, or other Matter of the like Nature, where the Expanſive, or Reſilient, or Elaſtick Force is ſo Balanc'd by the Contractive, that little or no Reſiliency Enſues, but a Perfect Quieſcence is Caus'd upon their Mutual Impaction; If the Velocity is Greater in the one than the other, they will proceed to the Side, from which the Weaker Velocity Acts, with the Exceſs of the Greater above the Leſs divided betwixt them; for the Body, which is Acted with the Greater Velocity, cannot move Faſter, than that, which was Acted with the Slower, becauſe this Latter lies before it, and it cannot move Slower, becauſe all the Velocity lies on the Side of the Former, therefore they will move Equably and together, and conſequently, the Exceſs of the Greater Velocity will be divided Equally betwixt them; Nor will this be altered, if A or the Sum of the Velocities is Greater than that of B; But, if A is leſs than B, ſo that, tho' the Velocity is Great, the Moment is too Small to move B, the Velocity of A will be Spent, either Backwards or Sideways. And the Preſent Caſe will be a Poſſible one, becauſe $E=c$, and $C=e$, and are not Æquations, which Contradict each other.

Caſ. 2. If $E=C$, and $e=c$, in the ſame Bodies, and $E=c$, and $e=C$, in different Ones, that is, if the Expanſive is Equal to the Contractive, in the ſame Bodies,

and

and, in Different Bodies, the Expanſive of one is Equal to the Contractive of the other, and the Expanſive of the Latter Equal to the Contractive of the Former, the Velocities, and the Quantities of the Forces continuing, as in Caſe the Firſt, Equal, there will likewiſe Ariſe a perfect Quieſcence from ſuch a Concourſe of Forces: Becauſe, ſince $E=c$ in different Bodies, and $e=c$ in the ſame Bodies, $E=e$; and ſince $e=C$ in different Bodies, and $e=c$ in the ſame, $C=c$; and therefore, all the Forces being Equally Balanc'd, as before, this Caſe will be Reſolv'd into the Former, tho' it is differently Expreſs'd; and it will be a Poſſible one, becauſe all the Æquations are Conſiſtent with each other.

Caſ. 3. If $E=C$, and $e=c$, in the ſame Bodies, and $E=e$, and $C>c$, in different Ones, it will be an Impoſſible Caſe, and cannot obtain in Nature; for $E=e$, and $e=c$, therefore $E=c$; likewiſe $E=e$, and $E=C$, therefore $e=C$; but $C>c$, and $e=c$, therefore $C>e$; and $C>c$, and $E=C$, therefore $E>c$; that is, $E=c$, and $E>c$, $e=C$, and $C>e$, which is Impoſſible.

Caſ. 4. If $E=C$, and $e=c$, in the ſame Bodies, and $E>e$, and $C=c$, in different Ones, it will be alſo an Impoſſible Caſe; becauſe $E=c$, and yet $>c$, and $C=e$, and yet $>e$, by a like Reaſoning with the foregoing.

Caſ. 5. If $E=C$, and $e=c$, in the ſame Bodies, and $E=c$, and $e>C$, in different Ones, this likewiſe will be an Impoſſible Caſe; becauſe $e=E$, and $>E$, and $c=C$, and $>C$, by the foregoing Reaſoning, which is Impoſſible.

Caſ. 6. If $E=C$, and $e=c$, in the ſame Bodies, and $E>c$, and $e=C$, in different Ones, the Caſe, as before, will be Impoſſible.

Why Two Equal and Differently Unelaſtick Bodies, Carry'd againſt each other with Equal Velocities may upon their Concourſe be Quieſcent; as alſo, Why an Unelaſtick Body, Deſcending upon another, do's not Rebound, but if the Velocity is Increas'd of Two Incurring ones, there is a Repulſion.

Caſ. 7. If $E=C$, and $e=c$, in the ſame Bodies, and in different Ones $E>e$, and $C>c$, this will be a Poſſible one; becauſe $E>e$, and $e=c$, and $C>c$ and $E=C$, therefore on both Hands $E>c$; On the Contrary $E>e$, and $E=C$, and $C>c$, and $e=c$, therefore on both Hands $C>e$; that is, A being $=B$, and $V=v$, E will Repell e with a Greater Force to a contrary Side or Direction, than e will Repell E to a contrary One, if nothing elſe was to be conſider'd; but C Acting againſt E with a Force Equal to it, it's Repulſive Force is Balanc'd with the Contractive, as likewiſe e with c, and tho' E Acts with c, yet C alſo Acting with e, there is nothing can Enſue from the Concourſe of ſuch Forces, but the Quieſcence of them, which is the Caſe of Two Unelaſtick Bodies, yet whoſe Intrinſick Forces differ from each other, as probably of Two Equal Globes of Pure and Unmix't Gold, (which is Soft and Unelaſtick) and of Lead, or of Lead, and Clay, and the like. It muſt alſo be obſerved of Unelaſtick Bodies, as Lead, that, if one is Quieſcent, and the other is made to Deſcend upon it, it will not Rebound from it, but if the Velocity of Two Leaden Bodies, Meeting each other, is Increas'd, there will be a Repulſion; which proceeds from the Expanſive of the Velocity being Greater than the Contractive of the Lead, by which means they Propell each other to Contrary Directions, and yet if one Leaden Body Deſcends upon another, which is Quieſcent, and the Velocity is Increas'd, it will not Rebound, becauſe the Expanſive of the Velocity Acts with the Contractive of the Quieſcent Body, and Tends the ſame Way, and there is no Expanſive of the Quieſcent to Repell it.

Caſ. 8. If $E=C$, and $e=c$, in the ſame Bodies, and $E>c$, and $e>C$, in different Ones; therefore $C>c$, and yet $c>C$, as alſo $E>e$, and yet $e>E$, which is again an Impoſſible One.

Caſ. 9. If $E=C$, and $e=c$, in the ſame Bodies, and $E=e$, and $C<c$, in different Ones; therefore $C=e$, and $<e$, $E=c$, and $<c$, which is Impoſſible.

Caſ. 10. If $E=C$, and $e=c$, in the ſame Bodies, and $E<e$, and $C=c$, in different Ones; therefore $E=c$, and $<c$, $C=e$, and $<e$, which is Impoſſible.

Caſ. 11. If $E=C$, and $e=c$, in the ſame Bodies, and $E=c$, and $e<C$, in different Ones; therefore $e=E$, and $<E$, $c=C$, and $<C$, which is Impoſſible.

Caſ. 12. If $E=C$, and $e=c$, in the ſame Bodies, and $E<c$, and $e=C$, in different Ones; therefore $E=e$, and $<e$, $C=c$, and $<c$, which is Impoſſible.

Caſ. 13. If $E=C$, and $e=c$, in the ſame Bodies, and $E<e$, and $C<c$, in different Ones; therefore $E<c$, and $C<e$, which is a Poſſible Caſe, and will exactly Correſpond with *Caſ.* 7. Excepting, that the Greater Forces will be in *Becv*, and the Leſſer in *AECV*, whereas the Greater Forces, in that Caſe, were in *AECV*, and the Leſſer in *Becv*.

Caſ. 14. If $E = C$, and $e = c$, in the ſame Bodies, and $E < c$, and $e < C$, in different Ones; therefore $E < e$, and $e < E$, as alſo $C < c$, and $c < C$, which is Impoſſible.

Caſ. 15. If $E = C$, and $e > c$, in the ſame Bodies, and $E = e$, and $C = c$, in different Ones; therefore $E = c$, and $> c$, and $e = C$, and $> C$, which is Impoſſible.

Caſ. 16. If $E = C$, and $e > c$, in the ſame Bodies, and $E = c$, and $e = C$, in different Ones; therefore $e = E$, and $> E$, $C = c$, and $> c$, which is Impoſſible.

Why an Unelaſtick Body, falling upon a Quieſcent Elaſtick, Rebounds from thence, but an Elaſtick falling upon a Quieſcent Unelaſtick, is not Reflected, but Unites and Cloſes with it, and if they meet with an Equal Velocity, the Elaſtick is Carry'd to the ſame Side with the Unelaſtick.

Caſ. 17. If $E = C$, and $e > e$, in the ſame Bodies, and $E = e$, and $C > c$, in different Ones; therefore $E > c$, and $C = e$, which is a Poſſible Caſe; That is, if the Expanſive Force in one Body is Equal to it's Contractive Force, and the Expanſive Force in the other Greater than it's Contractive, and in different Bodies, if the Expanſive Forces are Equal, and the Contractive Force of the Firſt Body is Greater than the Contractive of the Laſt, It will from thence follow, that the Expanſive of the Firſt is Greater than the Contractive of the Laſt, and the Contractive of the Firſt Equal to the Expanſive of the Laſt.

This will be the Caſe therefore of an Unelaſtick Body EC, whoſe Expanſive and Contractive Forces are in an Equal Balance, as ſuppoſing Lead, and of an Elaſtick Body ec, whoſe Expanſive is Equal to the Expanſive of the Former, but Greater than the Contractive of the Latter, and therefore Elaſtick, as ſuppoſing Marble is ſo, and which will have theſe Properties, which are found in Experience, and are Accounted for, by theſe Forces, as the Concourſe of Lead with Lead, or Gold with Lead, was, by *Caſ.* 1, 2, and 7.

1. That a Globe of Lead, Dropt upon a Marble or Stone Pavement, will be Repuls'd or Rebound from it, or, which is the ſame, a Globe of Lead, Incurring upon a Quieſcent, and Fixt Globe of Marble, will be Reflected from thence; becauſe the Expanſive Force of the Marble, which is Greater than it's Contractive Force, Acts Counter to the Expanſive and Contractive Force of the Lead, which are ſuppos'd to be Equally Balanc'd, and therefore Repells it, but as this Expanſive Force is Weak, and the Contractive of the Lead is Great, the Repulſion is Small; and it is not Impoſſible, but the Contractive Force of the Lead may be Greater than it's Expanſive, which will contribute ſtill more to the making the Repulſion from the Marble Leſs.

2. That a Ball or Globe of Marble, on the Contrary, Dropt upon a Pavement of Lead, or Incurring upon a Quieſcent, and Fixt Globe of it, is not Reflected, but rather ſeems to Tend downwards, if there is any thing below ſuch a Pavement, to which it can Tend, as in the firſt Caſe, or in the Second, Endeavours to Cloſe, and Unite with ſuch Globe; becauſe in this Caſe the Expanſive Force of the Marble Acts the ſame Way with the Contractive of the Lead, and therefore they rather Tend to an Union with, than a Separation from each other.

3. If neither of them are Quieſcent, the Globe of Lead, Meeting with a Globe of Marble with an Equal Velocity, and being Equal in their Bulk and Dimenſions, will Repell it, and Carry it to the ſame Side, to which it ſelf Moves; becauſe the Globe of Lead Acts with the Expanſive Force of it's Velocity, which is Equal to that of the Velocity of the Globe of Marble, but the Contractive Force of the Lead being Greater than that of Marble, for in the Preſent Caſe $C > c$, the Moment of ſuch Expanſive Force of the Velocity of Lead muſt be Greater than that of Marble, and therefore muſt Repell it to the ſame Side, ſince the Expanſive Forces E and e are Equal, but the Marble will not Rebound from the Lead, and will therefore proceed along with it, for the Reaſon alledg'd in *Art.* 2. Namely, becauſe e the Expanſive Force of the Marble Acts the ſame Way with C the Contractive of the Lead. We only bring theſe Two Bodies of Lead and Marble, as Inſtances of Unelaſtick and Elaſtick Bodies in General, tho' perhaps they may not have exactly the Conditions of this Caſe, that is, probably the Expanſive Force of the Lead may not be preciſely Equal to the Contractive of it, but much leſs, nor to the Expanſive of the Marble, for Silver, or Steel, or Iron, or other Metallick Subſtances, may perhaps come nearer to ſuch an Equality of the Expanſive in Lead, than Marble do's.

Caſ. 18. If $E = C$, and $e > c$, in the ſame Bodies, and $E > e$, and $C = c$, in different Ones; $E = c$, and $> c$, and $C > e$, and $e > C$, which is Impoſſible.

Why upon Concourſe the Elaſtick Body may not Rebound from the Unelaſtick, but the Unelaſtick from it.

Caſ. 19. If $E=C$, and $e>c$, in the ſame Bodies, and $E=c$, and $e>C$, in different Ones; therefore $e>E$, and $C=c$, which is a Poſſible Caſe, and will be that of an Unelaſtick and an Elaſtick Body, as in *Caſ.* 17; but, as there the Expanſive of the Firſt was Equal to the Expanſive of the Second, and the Contractive of the Firſt Greater than the Contractive of the Second, ſo here the Expanſive of the Firſt is Equal to the Contractive of the Second, and the Expanſive of the Second Greater than the Contractive of the Firſt; which may Poſſibly be very nearly the Caſe of an Unelaſtick and Elaſtick Body, which have the ſame Weights, where $e>E$, but $C=c$; But in this Caſe, ſomething Different from what was Obſerv'd on *Caſ.* 17,

1. The Unelaſtick Body, Impinging upon a Quieſcent, and Fixt Elaſtick, will Rebound or be Repell'd from it.

2. The Elaſtick Body, Impinging upon a Quieſcent, and Fixt Unelaſtick one, will not Rebound or be Repell'd from thence; And both theſe are Affirm'd, for the Reaſons, before Alledg'd, in *Caſ.* 17.

3. If they meet each other with an Equal Velocity, the Elaſtick will not Rebound from the Unelaſtick, but the Unelaſtick from it; becauſe, their Velocities being not only Equal, but the Moments of them, the Greateſt Force will lie on the Side of the Expanſive e againſt EC, whoſe Forces are in an Equal Balance; And This may be the Caſe of Marble and Dry'd Clay; ſince $E=C$ in the Clay, and $e>c$ in the Marble; likewiſe E in the Clay $=c$ in the Marble, and e in the Marble $>C$ in the Clay; and therefore e in the Marble $>E$ in the Clay, and C in the Clay $=c$ in the Marble, from whence it is neceſſary, that e in the Marble ſhould Prevail, and Propell the Clay from it.

Caſ. 20. If $E=C$, and $e>c$, in the ſame Bodies, and $E>c$, and $e=C$, in different Ones; therefore $E=e$, and $C>c$, in different Ones; which likewiſe is a Poſſible Caſe, where the Unelaſtick Body is EC, whoſe Expanſive and Contractive Forces are in an Equal Balance, and the Elaſtick ec, in which e is Greater than c, as in all the foregoing Caſes, from *Caſ.* 15; And here $E=e$, and $C>c$, as alſo $E>c$, and $e=C$, makes it Exactly the ſame with *Caſ.* 17.

Why an Elaſtick Body may not Repell the Unelaſtick, but be Carry'd to the ſame Side with it.

Caſ. 21. If $E=C$, and $e>c$, in the ſame Bodies, and $E>e$, and $C>c$, in different Ones; therefore $E>c$, and $C>=<e$; if $C<=e$, it is an Impoſſible Caſe; if $C>e$, it will be a Poſſible One: EC, as before, is the Unelaſtick Body, and ec the Elaſtick, but the Expanſive of the Firſt is Greater than the Expanſive of the Second, and the Contractive of the Firſt, than the Contractive of the Second; likewiſe the Expanſive of the Firſt is Greater than the Contractive of the Second, and the Contractive of the Firſt, than the Expanſive of the Second; which may be the Caſe of Lead and Glaſs, where the Firſt is more Expanſive, but is Balanc'd by it's Greater Contractive, and the Laſt is Leſs Expanſive and Leſs Contractive, but the Expanſive is Greater than the Contractive: Upon the Concourſe therefore of theſe Two Bodies,

1. The Unelaſtick Body, Impinging upon a Quieſcent, and Fixt Elaſtick, will not Rebound, or be Repell'd from it; becauſe the Expanſive of the Elaſtick is too Weak to Produce that Effect, and the Moment of the Expanſive and Contractive in the Lead too Strong to admit of ſuch a Repulſion.

2. The Elaſtick Body, Impinging upon a Quieſcent, and Fixt Unelaſtick, will not Rebound, or be Repell'd from thence, for the Reaſons, before Alledg'd, in *Caſ.* 17. *Art.* 2.

3. If they meet each other with an Equal Velocity, the Elaſtick Body will not Repell the Unelaſtick, but the Moment of the Unelaſtick, being Greater, will carry the Elaſtick to the ſame Side with it.

Why a Body which is Extremely Elaſtick Fuſes and Raiſes into an Ebullition an Unelaſtick one.

Caſ. 22. If $E=C$, and $e>c$, in the ſame Bodies, and $E>c$, and $e>C$, in different Ones; therefore $C>c$, and $C<=>c$, and $e>E$, and $E<=>e$; which Caſe likewiſe will be Poſſible, if $C>c$ and $e>E$ on both Hands, and may probably be that of Lead and Fire; Since the Contractive Force of Lead is Greater than the Contractive of Fire, and the Expanſive Force of the Fire is Greater than that of Lead, as alſo, the Expanſive Force of the Lead is Greater than the Contractive of the Fire, and the Expanſive of the Fire Greater than the Contractive of the Lead; From whence it comes to Paſs, that the Expanſive Force of the Fire, being Greater than that of Lead, Repells it, by which it's Ebullition is cauſed upon the Fuſion of it, and being Greater than the Contractive Force of Lead Fuſes it, for they Act the ſame Way; and E being $>c$, and $C>c$, that is, the Expanſive Force of the Lead, being Greater than the Contractive of the Fire, and the Contractive of the Lead, Greater than the Contractive of the Fire, will have no Effect, becauſe E and C are in an Equal Balance with each other, and as E Acts with c, C Acts againſt it. And this is, ſuppoſing Lead is Quieſcent, and Fire Acts upon it. For, as to Velocity in this Caſe, the Expanſive Force of the Fire is ſo Great, that no Communication of the Expanſive Force, as that of Velocity, can give any Moment to it, by which means it will Act upon Lead with it's own Expanſive, which is Peculiar to it ſelf, and by it Diſſolve Firſt, and then Repell it, as has been before ſaid; And if Lead is carry'd againſt it with a certain Velocity, the whole Moment of the Expanſive of the Lead, join'd with it's Great Contractive, will be ſo much Superior to the Expanſive of the Fire, which has but a Small Contractive belonging to it, that it will Paſs through it, with Little or No Oppoſition. And here we muſt obſerve in General, in Reſpect of theſe Concourſes, that Groſſer Expanſive Bodies Require a Velocity to Diſplay their Particular Actions, by ſuſpending their Gravitation, which Hinders and Suppreſſes Them; But it is not ſo in Fire, whoſe Vaſt Expanſive Force ſurmounts all Oppoſition to it from the Earth's Attraction.

Caſ. 23. If $E=C$, and $e>c$, in the ſame Bodies, and $E=e$, and $C<c$, in different Ones; therefore $E>$, and $<c$, and $e=C$, and $>C$, which is Impoſſible.

Caſ. 24. If $E=C$, and $e>c$, in the ſame Bodies, and $E<e$, and $C=c$, in different Ones; therefore $E=c$, and $E=><c$, and $C\leq e$, ſo that ſuppoſing $E=c$, and $C<e$, this will likewiſe be a Poſſible Caſe.

The Remaining Caſes I ſhall only juſt Mention, and leave to others to Inquire, which are Poſſible, and which not, and to what Kind of Elaſtick, and Unelaſtick Bodies they are Applicable, which is eaſily done by Proceeding in the Method before ſet down.

Caſ. 25.	$E=C$, $e>c$		$E=c$, $e<C$	
Caſ. 26.	$E=C$, $e>c$		$E<c$, $e=C$	
Caſ. 27.	$E=C$, $e>c$		$E<e$, $C<c$	
Caſ. 28.	$E=C$, $e>c$		$E<c$, $e<C$	
Caſ. 29.	$E=C$, $e<c$		$E=e$, $C=c$	
Caſ. 30.	$E=C$, $e<c$		$E=c$, $e=C$	
Caſ. 31.	$E=C$, $e<c$		$E=e$, $C>e$	
Caſ. 32.	$E=C$, $e<c$		$E>e$, $C=c$	
Caſ. 33.	$E=C$, $e<c$		$E=c$, $e>C$	
Caſ. 34.	$E=C$, $e<c$	in the ſame Bodies; and	$E>c$, $e=C$	in different Ones.
Caſ. 35.	$E=C$, $e<c$		$E>e$, $C>c$	
Caſ. 36.	$E=C$, $e<c$		$E>c$, $e>C$	
Caſ. 37.	$E=C$, $e<c$		$E=e$, $C<c$	
Caſ. 38.	$E=C$, $e<c$		$E<e$, $C=c$	
Caſ. 39.	$E=C$, $e<c$		$E=c$, $e<C$	
Caſ. 40.	$E=C$, $e<c$		$E<c$, $e=C$	
Caſ. 41.	$E=C$, $e<c$		$E<e$, $C<c$	
Caſ. 42.	$E=C$, $e\leq c$		$E<c$, $e<C$	

In the ſame Bodies. In different Ones.

$E>C$, $e>c$		$E=e$, $C=c$
		$E=c$, $e=C$
		$E=e$, $C>c$
$E>C$, $e=c$		$E>e$, $C=c$
		$E=c$, $e>C$
		$E>c$, $e=C$
$E>C$, $e\leq c$	Each of the Diviſions in the Firſt Column may be Combin'd with Every one of the Diviſions in the Second.	$E>e$, $C>c$
		$E>c$, $e>C$
		$E=e$, $C<c$
$E\leq C$, $e<c$		$E<e$, $C=c$
		$E=c$, $e<C$
		$E<c$, $e=C$
$E\leq C$, $e=c$		$E<e$, $C<c$
		$E<c$, $e<C$
$E\leq C$, $e>c$		

Caſes 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, &c.

From

This Doctrine ſufficient for all the Infinite Variety of Caſes in the Mutual Concourſe of Bodies.

FROM whence will Ariſe 84 Caſes more, which Added to 42, before Set down, will Make 126, Poſſible and Impoſſible Ones, ſo that here cannot but be a ſufficient Latitude for the Explaining of the Mutual Concourſe of all Bodies; Eſpecially, when we likewiſe Conſider, that theſe Forces may be Equal, Greater or Leſs than each other in an Infinite Number of Degrees, thus $3 = 3$, $4 = 4$, $100 = 100$, *&c.* $10 > 7$, or 5, or 3, or any Number below it, and $5 < 10$, or 50, or 1000, or any Number above it; from whence it will follow, that if the Peculiar Expanſive and Contractive Forces of Bodies are vary'd to Infinity, as it is Reaſonable to think they are, which muſt cauſe Effects very Different upon their Meeting each other, the foregoing Theory will Account for all of them; whereas the Modern and Receiv'd Explication of ſuch Concourſe will be Infinitely Defective and Imperfect, which ſuppoſes no Innate Forces in Bodies, but that they are Similar and Homogeneous, and are only Acted by Two Imaginary Ones, Simple Impulſe and Elaſticity.

WHAT has been hitherto ſaid is upon the Suppoſition of the Velocities being Equal, but, if they are Various, there will be new Combinations Produc'd, and a Series of Caſes ſtill Different from the Former.

What Problems we ſhall be able to Solve, when we have Determin'd the Preceding Caſes.

§. 35. WHEN we have gone thro' this Theory of the Expanſive and Contractive Forces, and have Determin'd all the Poſſible Caſes, it will be then eaſy for us to Reſolve the following Problems.

1. WHAT will be the Effect of Two Unelaſtick Bodies, one falling upon the other, which is Quieſcent, and Fixt, with a Certain, a Greater, or a Leſs Velocity.
2. WHAT will be the Effect of Two Unelaſtick Bodies, one falling upon the other, which is not Fixt, but is Quieſcent in a Certain, a Greater, or Leſs Degree, with a Certain, a Greater, or a Leſs Velocity.
3. WHAT will be the Effect of Two Unelaſtick Bodies, one falling upon the other, which is in a Certain, a Greater, or Leſs Motion the ſame Way, with a Certain, a Greater, or Leſs Velocity.
4. WHAT will be the Effect of Two Unelaſtick Bodies, one falling upon the other, which is in a Certain, a Greater, or Leſs Motion the Contrary Way, with a Certain, a Greater, or a Leſs Velocity.
5. WHAT will be the Effect of Two Unelaſtick Bodies, falling the one upon the other, whoſe Unelaſticity is Greater, or Leſs than the Former, with their ſeveral Variations of Quieſcence, and Velocity, mention'd above.
6. WHAT will be the Effect of Two Bodies, the one falling upon the other, the one Elaſtick, and the other Unelaſtick, in Equal or Different Degrees of thoſe Forces, with their ſeveral Variations of Quieſcence, and Velocity, mention'd above.
7. WHAT will be the Effect of Two Elaſtick Bodies, in Equal or Different Degrees of thoſe Forces, the one falling upon the other, with their ſeveral Variations of Quieſcence, and Velocity, mention'd above.

Some Problems ſolv'd in General, upon which the others Depend.

§. 36. IN Relation to all theſe Problems, I ſhall only take Notice (and which we have in Part already done) of Two Unelaſtick Bodies, Two, which are Elaſtick, and Two, one of which is Elaſtick, and the other Unelaſtick, and where one falls upon the other, which is Quieſcent and Fixt; becauſe all the other Caſes are only Differenc'd by the ſeveral Combinations of theſe.

Firſt, Why an Unelaſtick Body falling upon another Unelaſtick Cloſes and Unites with it; farther Explain'd.

AND Firſt, if an Unelaſtick Body falls upon another (which is Equally Unelaſtick, and is Quieſcent and Fixt) with a Certain Velocity Ariſing from it's Gravitation, it will Seem to Cloſe and Unite with it; becauſe there is an Expanſive Force in the Velocity, which Acts the ſame Way with the Contractive of the Quieſcent, and is Superior to the Contractive of the falling Body, as the Contractive Force of the Earth is Superior to the Contractive Force of ſuch Body, and which, Acting contrary to it, has the Nature of the Expanſive; from whence it is, that a Bullet of Lead, Dropt upon a flat Piece of it, does not Rebound from it, but Endeavours to Cement and Join with it.

AND if there is a Greater Expanſive Force or Velocity, Communicated to the Bullet by the Hand, it ſtill leſs Rebounds, but makes Impreſſions into it, and Indentations in it, or Tends to a Situation below the Lead, on which it falls; becauſe the Expanſive Force of the Lead falling, is Increaſed, and ſtill Acts with the Contractive of the Quieſcent, and in the ſame Direction: If the Lead is not Fixt, as in Pendulums,

lums, or is in Motion the Same, or the Contrary Way, with the falling Bullet, tho' Allowances are to be made for the Expanſive Force of Velocity in the Lead, on which the Impaction is made, yet what foregoes holds true, when we have made thoſe Allowances; Thus Two Equal Leaden Bullets, Meeting with an Equal Velocity, will loſe their Motion, becauſe the Contractive Force of each, Acting towards it's own Center cauſes no Repulſion, and the Equal Expanſive Forces of the Velocities deſtroy each other.

Sir Iſ. Newt. Optic. Queries.

It muſt be alſo obſerv'd, that as the Unelaſtick Force of Lead is Different from that of Clay, ſo the Effect of one Piece of Clay falling upon another, which is Quieſcent and Fixt, will be likewiſe in Degree Different, but the Solution of the Adheſion of one to the other, will be the ſame as before; And the like may be ſaid of Lead and Clay in their Mutual Concourſe.

Second, Why Elaſtick Bodies are Repell'd from each other.

Second, If an Elaſtick Body falls upon another, which is Elaſtick, with a Certain Velocity Ariſing from it's Gravitation, as a Ball of Marble upon a Piece of Marble, which is Quieſcent and Fixt, it will be Repell'd from thence; becauſe the Expanſive Force of the Marble, which falls, Acts with the Expanſive Force or Velocity proceeding from Gravitation, but the Expanſive Force of the Marble, on which the Impaction is made, Acts Contrary to the Former Force, and being not only Quieſcent, but Fixt, the Superior Incurring and Expanſive Force, not being able to ſpend it ſelf that Way, muſt neceſſarily Reſult from it, to which the Repulſive Force of the Fixt Marble will alſo Contribute.

If this Expanſive Force is Increas'd by an Acceſſion of Velocity Impreſs'd from the Hand, the Impinging Marble will Rebound the Higher; If Two Balls of Marble Meet each other, they will mutually Repell each other from their Expanſive Force Acting Contrary Ways, and deriv'd from their Elaſticity and Velocity; and if the Velocity is Increas'd, the Repulſe will be the Stronger: Farther, if a Marble is let fall upon a Flint Glaſs, which is a more Elaſtick Body than Marble, it will Rebound more, than when it fell upon Marble, becauſe the Reſiliency is Greater from the Greater Expanſive Force of the Glaſs; and if Two Glaſs Balls Meet, they will be more forcibly Repell'd than Two Balls of Marble; or, if the Glaſs Balls Meet each other with a Greater Velocity, they will be more ſtrongly Repell'd, than if they met with a Leſs; becauſe on both Hands the Expanſive Force is Increas'd.

Mr. Hauksbee's Experiments, Pag. 106.

I ſhall only here add, that upon the ſame Principles are ſolv'd the Experiments, made by the moſt Judicious and Ingenious Mr. *Hauksbee* upon the Preſent Subject of Repulſion, even in Reſpect of Different Mediums, (which yet is the leaſt Thing to be Conſider'd in the Rebounding of Different Bodies, where their Innate and Intrinſick Forces are to be Examin'd) for a Thicker Medium, being more Contractive, hinders the Expanſive, by which Reſilition is Perform'd, and a Thinner Medium, being leſs Contractive or more Expanſive, Promotes it.

Why an Unelaſtick Body, falling upon an Elaſtick, is Repell'd from it, but if an Elaſtick falls upon an Unelaſtick, it Cloſes and Unites with it; farther Explain'd.

Third, If an Unelaſtick Body falls upon an Elaſtick, which is Quieſcent and Fixt, with a Certain Velocity, Ariſing from it's Gravitation, it will be Repuls'd from thence, thus a Ball of Lead, falling upon Marble, will Rebound from it; On the Contrary, If an Elaſtick Body falls upon an Unelaſtick, as a Ball of Marble upon Lead, there is no ſuch Repulſion, but the Marble Endeavours to Cloſe and Unite with the Lead, and ſtrikes off in a Lateral Direction.

The Reaſon of which is, becauſe in the Former Caſe, the Contractive of the Lead, and the Expanſive of the Marble Act Upwards, and in the Latter Downwards in the ſame Direction; For the Contractive of the Lead Acts towards it ſelf, and the Expanſive of the Marble from it ſelf, in the Firſt Inſtance, that is, the ſame Way Upwards; and in the Second, the Expanſive of the Marble Acts from it ſelf, and the Contractive of the Lead towards it ſelf, that is, the ſame Way Downwards.

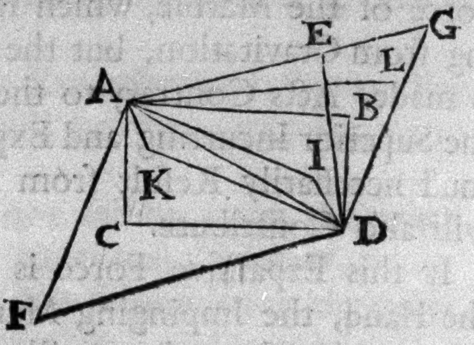
And in the Firſt Caſe, if the Velocity is Increas'd, the Repulſion is likewiſe; becauſe Acting againſt the Expanſive of the Marble, and it's Progreſs being there ſtopt, it is Return'd backwards in the Direction of the Expanſive, and the Contractive of the Lead has Leſs Force, by how much the Expanſive of the Velocity is Greater.

But in the Second, If the Velocity is Increas'd, the Marble Tends with a Greater Force towards an Union with the Lead, on which it Impinges, and is ſtill farther from Rebounding; becauſe the Velocity Acts the ſame Way with the Expanſive of the Marble, and with the Contractive of the Lead, that is, Downwards.

I might here farther Enlarge, but ſhall leave the Remaining Particulars in this Doctrine, to be Traced out and Examin'd by others, who ſhall think it worth their Leiſure and their Inquiry, being Satisfied in having Pointed out the way for Greater Advances and Improvements in this kind of Knowledge, than has been hitherto Attempted by any of the Mechanick Philoſophers: I ſhall only here Add, that, ſince Hydroſtaticks are the Laws, which Ariſe from the Concourſe of Solid and Fluid Bodies, They likewiſe are Explicable by theſe Expanſive and Contractive Forces, as we ſhall ſhew, when we come to Treat of Them.

The Compoſition of Forces Explain'd. Sir Iſ. Newt. Princ. Math. Lex. 3. Corol. 1. Mr. Whiſton's Phyſ. Math. Prælect. 6. Art. 22.

§. 37. HAVING conſider'd Action and Re-action, and the ſeveral Laws of Unelaſtick and Elaſtick Bodies, we are next to Inquire into the Compoſition of Forces; in Reſpect of which, the Diagonal Force is ſaid to be Equal to that of the Sides of a Parallelogram, drawn from the ſame Point with it; Thus *A D* is Equal, in it's Joint Force, to *A B* and *A C*, the Separate Ones: Becauſe *A*, in it's Progreſs to *B*, is not Interrupted by the Force, which Directs it from *A* to *C*, nor *A* to *C*, by that, which carries it from *A* to *B*, ſo that it ſhou'd not Proceed ſo far, as *B* on the one Hand, and as far as *C* on the Other; that is, both theſe Forces are Conſiſtent, and by Conſequence muſt meet in *D*; I call theſe Forces Equal, the Diagonal to the Lateral, becauſe the Firſt are Reſolv'd into the Laſt, and the Laſt Compound the Firſt, according to this Philoſophy, in it's uſe of this Compoſition of Forces.



This Compoſition of Forces contrary to Mathematick Demonſtration. Mr. Whiſton. Prælect. 6. Corol. 5.

§. 38. IN Anſwer to which we muſt Firſt ſay, that, by *Euclid*, Elem. 1. Prop. 47. Schol. *Tacquet*, if *ABDC* is a Square, *AD* is Incommenſurable with the Side *AB* or *AC*, how therefore both together ſhould be Equal to *AD*, is not to be Explain'd, ſince the Forces are as the Spaces, which they Deſcribe in the ſame Time; therefore there muſt be a Thicker and more Compreſs'd Force in a *AD*, and a more Thin and Diluted one in *AB* and *AC*, and which will be Equal the one to the other; but this is Impoſſible, according to the Demonſtration Refer'd to, becauſe theſe Quantities are Incommenſurable, and have no Common Meaſure, by which their Equality, or any other Proportion betwixt them, can be Aſſerted; I muſt own this may be, that a Thicker and a more Conſtipated, or a Stronger Force, may be Reſolv'd into Two Thinner, and more Diluted or Weaker, and that they may be Expreſs'd by theſe Lines, ſuppoſing *AD* a more Conſtipated one, and *AB*, *AC* leſs ſo; but this is what, neither the Preſent Mathematicks, nor the Preſent Philoſophy, or Compoſition of Forces conſiders; and therefore, I argue againſt this Abſtracted Reaſoning in the Compoſition of Forces, from another Abſtracted Reaſoning in the Demonſtrations of Geometry, which I ſay are Inconſiſtent, as Abſtracted Reaſonings, which are the Mere Creatures of Men's Minds will generally be found to be; and not only in theſe, but in all other Studies, as in Logicks, Metaphyſicks, and even in Critique, and the Explanations of Authors, in which there are very Singular Inſtancesof Thoſe, who delight more in Abſtracted Fancies of their own Minds, than in any Real and Solid Reaſoning.

Another Objection againſt it. Mr. Whiſton. Prælect. 6. Corol. 1.

§. 39. A Second Objection is, that as the Angle *BAC* is Greater or Leſs, the Velocity of *A* to *D* will be Leſs or Greater, when yet the Velocities given of *A* to *B* and *C* are ſuppos'd to be Unalter'd; Becauſe where the Angle is Leſs, as in *IAK*, the Direction of the Velocities, which were before in *AB*, *AC*, Tends the ſame Way, but where the Angle is Greater, as in *GAF*, contrary Ways, and therefore the Velocity is Increas'd in *AD* in the Firſt Caſe, and Diminiſh'd in the Laſt; This, we ſay, is a Second Objection againſt the Preſent Compoſition of Forces, ſince, if *AD* is not certain and determin'd in the Force, which it Expreſſes, and ſince ſeveral Forces are the moſt naturally Repreſented by ſeveral Lines, *AB* and *AC* in their various Inclinations and their differing Degrees of Velocity cannot be truly Expreſs'd by one and the ſame Diagonal *AD*, nor can *AD* be juſtly Reſolv'd into them.

§. 40. BESIDES,

§. 40. Besides which, ſuppoſing the Forces, *AB*, *AC*, cou'd be Expreſs'd by the Diagonal *AD*, it is yet Evident, that *AD* cannot be Reſolv'd into the Forces, *AB*, *AC*, at Pleaſure, that is, we may not draw Lines with what Inclination we pleaſe to *AD*; or, which is the ſame, altho' the Forces, *AB*, *AC*, being known, their Compound is determin'd by the Diagonal *AD*, yet, the Diagonal being known it is not Conſequent, that the Forces, which form it, ſhou'd be, becauſe there may be a Thouſand Different Sides of a Parallelogram drawn to the ſame Diagonal; notwithſtanding which, there is nothing more Common in the Philoſophy, which this Notion is brought to Eſtabliſh, than the Reſolving the Diagonal into any Lines, which it finds the moſt convenient for it's Purpoſe, as is Evident in the Explanation it gives of the Doctrine of Mechanicks, and in the Solutions it propoſes of the Revolution of the Secondary Planets about their Primary.

A Third Objection againſt this Compoſition of Forces.

Sir If. Newt. Princip. Lex. 3. Corol. 2.

§. 41. Thus far we have conſider'd the Force repreſented by the Diagonal, and from thence ſhall Proceed to thoſe of the Sides of the Parallelogram, which were ſaid to be vary'd according to *AB* and *AC*, more or leſs, oppoſing each other in the Direction of thoſe Forces, that is, as the Angle *BAC* was Greater or Leſs; but if this will not be Allowed, and if the Velocity from *A* to *B* is given, and that of *A* to *C*, and it is ſaid, that, in whatever Direction they are, they will continue the ſame, becauſe if *A* Acts towards *B* with a certain Force, and towards *C* with another certain Force, ſince the Fountain or Source of Action is ſuppoſed to be in *A*, whatever Inclination the Lines, *AB*, *AC*, have to each other, it can be of no Importance to the Altering of the Velocities propagated from thence, let this Reaſoning then be Allow'd;

This Compoſition of Forces not True upon another Account.

Mr. Whiſton. Prælect. 6. Art. 22.

If therefore *AB* and *AC* have their fixt and determin'd Velocities in any Inclination we can mention, it will be Impoſſible, that *AD* the Diagonal ſhould expreſs them; becauſe, if *AE* is made Equal to *AB*, *ED* will be one Side of the Parallelogram, to which it is Inconceivable *AC* ſhould be Equal, which is ſuppoſed to be the Expreſſion of it's Velocity, and to be Unalter'd.

§. 42. Another Objection is, that *AB* and *AC* muſt, each of them, Act with the ſame Velocities, in whatever Inclination they are, or not; If they do, the foregoing Section is Valid in it's Argument againſt the Preſent Compoſition of Forces, if they do not, ſince the Velocities are Diminiſh'd by Oppoſing each other, or Increas'd by Concurring in differing Inclinations, it will be the ſame, as Contracting or Prolonging the Sides of the Parallelogram in the ſame Inclination, and conſequently, the Diagonal *AD* will be ſuitably made Shorter or Enlarg'd, which is far from agreeing with this Doctrine, which ſuppoſes, that the Diagonal may continue the ſame, altho' the Sides of the Parallelogram are Infinitely vary'd; thus, if *AB*, *AC* are Equal, and recede from each other, till they are perfectly Oppoſite, the Forces, Acting from *A* in contrary Directions, will mutually hinder each others Progreſs, if they approach each other, till they Coincide, the Velocity will be the Sum of both, and therefore all the intermediate Effects, produced in the ſeveral Inclinations of *AB*, *AC*, ſhould not be Expreſs'd by one and the ſame Diagonal Line *AD*, but by an Infinite Number of different Lines of various Lengths betwixt 0, repreſented by a Point, and *AB* + *AC*, which repreſents the Sum of the Forces.

A farther Difficulty Explain'd, which lies againſt this Compoſition of Forces.

§. 43. There is likewiſe a farther Thing to be conſider'd in this Doctrine, namely, that *AF*, *AG*, Parallel and Equal to *GD*, *FD*, are conceiv'd to be the ſame in all Reſpects with *AC* and *AB*, in their Relation to the Diagonal *AD*, and all the Parallelograms, drawn to the ſeveral Parts of *AD* from the ſeveral Parts of *AC* and *AB* on the one Hand, or from *AF* and *AG* on the other, exactly Correſpond in their Diagonal Portions of *AD*, from whence it follows, that the Reſult of the Forces on both Hands are Equal, if the ſame Lines or Parts of a Line are Expreſſive of the ſame Forces, which they ought to be; whereas it is confeſs'd, that, when the Forces Concurr, that is, when *AB* Approaches to *AC*, or when they are Oppos'd, as in their Retiring from each other, the Reſult of the Forces are not Equal, and conſequently cannot be Expreſs'd by the ſame Diagonal Portions; that is, the Preſent Doctrine ſuppoſes the Reſult of the Forces to be Equal, and not Equal at the ſame Time, which is an Abſurdity and a Contradiction.

A Sixth Objection.

Mr. Whiſton. Prælect. 6. Corol. 1.

A Seventh Objection. Prælect. 6. Art. 22,

§. 44. We muſt alſo add, that even the Foundation of this Doctrine of the Compoſition of Forces is not certain, for if a Force is propagated Two Different and even Contrary Ways from *A*, it cannot be altered from thence, becauſe Two ſuch Forces will have no Effect or Influence upon each other, and therefore *AB* and *AC* may be both deſcribed without any Diagonal at all, that is, if we conſider only the Action of Two Forces from the ſame Point, and that any thing more is Prov'd from this Figure is not Certain, ſince the Sides of a Parallelogram may be deſcribed by Two Forces, without ſuppoſing them to be Compounded into a Diagonal; if Two Forces are not ſuppoſed to Act from the ſame Point, but upon it, what has been Alledg'd in §. 42 and 43 will be Valid, if the other, §. 41 will.

Another Objection againſt this Compoſition of Forces.

§. 45. Farther, If *A* is Acted by Two Different Forces repreſented by *AB*, *AC*, it will not yet follow, that the Compound of them ſhould Proceed in the Diagonal *AD*; becauſe after the Action at *A* they are ſuppoſed to preſerve their Original Velocities, *AB* and *AC*, otherwiſe they would not meet in the Point *D*, which is upon the Hypotheſis, that *A* has the Force to carry it to *B*, and to *C*, in which the Parallel Lines to them *CD* and *BD* Concurr; if therefore *A* preſerves it's Velocity to *B* and to *C*, and conſequently it's Direction, for by thoſe Lines and thoſe Directions both the Velocities are Expreſs'd, how they ſhou'd preſerve them in the Diagonal *AD*, where the Direction and the Line is Different, will be Impoſſible to Explain.

The Ninth Objection.

§. 46. On the Contrary, If *AB* and *AC*, after the Action upon *A*, do not preſerve their Velocities, that is, if *A*, by being Acted upon, goes in the Line *AD*, ſo as the Velocities of *AB* and *AC* are Chang'd, *AD* will not be neceſſarily the Diagonal of a Parallelogram, becauſe the Sides of it, and the Velocities repreſented by them, will be Deſtroy'd; that is, ſuitable to what we ſaid before, in §. 44, the Sides of the Parallelogram will continue without a Diagonal, and in this, the Diagonal or rather the Line *AD*, without any Sides, to which it is Refer'd, and Half, or a Quarter, or any other Part, of *AD* may repreſent the Compound of *AB*, *AC*.

What the Truth is in this Caſe.

§. 47. The Truth is in any Compoſition of Motion, or of Forces, as of *AB*, *AC*, it goes a Greater or Leſſer Length in *AD*, not as *AB* or *AC* are the Sides of a Parallelogram, but according as the Forces are Greater or Leſs which Act; becauſe if *AB* and *AC* were to approach Infinitely near to Each other, *A* wou'd be carried with the Force of *AB* + *AC* in a Direct Line, which wou'd be Greater than *AD* the Diagonal; and where *AB* and *AC* are as far from Each other as poſſible, the Compoſition of Forces will be much Leſs than the Diagonal, being reduc'd to a Point, and the ſame may be ſaid of all the intermediate Degrees of Compoſition, with the Allowance of Greater and Leſs in Proportion, according to what has been before mention'd.

A Tenth Objection. Mr. Whiſton. Prælect. 6. Corol. 3.

§. 48. If nothing of what, we hitherto have argu'd, was certain, this is acknowledg'd, that, the Forces being given, the Diagonal is known, but, the Diagonal being known, the Forces Expreſs'd by the Sides of the Parallelogram are not, ſince, according to this Doctrine, there may be ſeveral Sides of a Parallelogram drawn to the ſame Diagonal; but if, upon the Diagonal being known, the Sides are yet Latent and Undiſcover'd, this Philoſophy will want it's main Support, both in the Explanation of Mechanicks, and of the Revolutions of the Secondary Planets, in which it takes it for granted, that, the Diagonal being known, the Sides are no longer a Secret.

The Eleventh Objection.

§. 49. We ſhall laſtly ſubjoin, that it is Impoſſible in the preſent Caſe, if the Forces, *AB*, *AC*, are Compounded into *AD*, but they ſhou'd again be Reſolv'd into them in Reſpect of their Length, unleſs *AD* can be ſhorter than *AB* and *AC* taken together, and yet Expreſs the ſame Force; that is, where Forces are Reduced to Lines, thoſe Lines are Expreſſive of them, or not; if they are, it is abſurd to ſay, that *AB* + *AC* is = *AD*, if they are not, *AB* and *AC* are not the Expreſſions of the Forces, which they are, notwithſtanding, made to repreſent, which is a Contradiction. If it be ſaid, in Reſpect of theſe Two laſt Sections, and of this whole Doctrine, That *AD* may be Reſolv'd into *AI* and *AK* or *AID*, into *AB* and *AC* or *ABD*, into *AG* and *AF* or *AGD*; becauſe they are all the ſame, that is, becauſe they are Forces perfectly Equivalent; and if it be farther ſaid, that theſe Forces are the Same or Equivalent, becauſe, by the Law of Action and Re-action, to which this Compoſition of Forces is made a Corollary, where the Force *AI* is

Leſs than *AD*, the Concurrent Force *AK*, in the Inclination *IAK* will make it juſt Equal to it, or the Force *AID* = *AD*, on the Contrary, where the Force *AG* is Greater than *AD*, by the ſame Law of Action and Re-action, the Oppoſite Force *AF*, in the Inclination *GAF*, will take away ſo much from it, as to make it exactly Equal to it, or *AGD* = *AD*, and ſo the Nearer *AI* and *AK* Approach to Each other, they will come Nearer to an Equality, that is, *AID* will come Nearer to a Coincidence with *AD*, and the farther *AG* and *AF* Retire from Each other, the Longer they will be, that is, their Forces will be the Greater, as their Oppoſition is ſo, in Order to make them Equal to the ſame Force *AD*; If this is ſaid, We Anſwer,

1. That it is not Prov'd, that the Concurrence of *AI* with *AK*, in the Inclination *IAK*, or that the Oppoſition of *AF* to *AG*, in the Inclination *GAF*, adds juſt ſo much to the one, and takes off juſt ſo much from the other, as to make them, on both Hands, Equal to *AD*; Eſpecially, ſince betwixt *AG*, which is Greater than *AD*, and *AB* which is Leſs, there muſt be a Line, which is Equal to it, as for Inſtance *AL*, and conſequently it's Oppoſite Force, which Acts againſt it, muſt either have no Force at all, and then there is an End of theſe Oppoſite Forces, or if it has, *AL* together with it will be Leſs than *AD*, contrary to what was propos'd to be Demonſtrated.

2. Therefore, where *AI* or *AB* are Leſs, and *AG* Greater than *AD* or *AL*, their Concurrent or Oppoſite Forces will not make them Equal to *AD*.

3. Since *AI* and *AK*, *AG* and *AF*, are Velocities perform'd in the ſame Time, they will be in themſelves Different, but how the Addition of Two Different Velocities, which Concurr, or the Subſtraction of Two from Each other, which are Oppoſite, ſhou'd be Equal to one Uniform Velocity in *AD* will be hard to Explain.

4. Granting yet all, which can be deſir'd, ſince there may be a Thouſand Different Velocities and Forces in *AD*, for it may be deſcrib'd by any Force or Velocity Given, how the ſame Sides of a Parallelogram, as *AB*, *AC* or *BD*, ſhould be Equal to all thoſe Varying Forces, cannot be ſhewn; Thus ſuppoſing *AD* to Expreſs the Force of Gravitation of one Body to another, and that *AB* and *BD* will likewiſe do it, which is Preſum'd in the Theory of the Secondary Planets, if, notwithſtanding, there are Different Forces of Gravitation Expreſſible by the ſame Line *AD*, *AB* and *BD* conſider'd only as Sides of a Parallelogram, of which *AD* is the Diagonal, will not be ſufficient to Repreſent them; that is, this Reaſoning proceeds upon Abſtracted Lengths and Lines, whereas, according to the *Geometry* of *Solids*, there may be very Different Forces or Quantities in the ſame Abſtracted Lengths, as we have there endeavour'd to Evince.

§. 50. After conſidering the Foundation, on which this Compoſition of Forces ſtands, we might next Examine, what uſe is made of it, but if the Foundations of a Doctrine are not True, the Applications of it muſt be Falſe, and therefore we may be juſtly excuſed the Trouble of a farther Inquiry on this Head.

The Application of this Doctrine not neceſſary to be Conſider'd.

However to confirm this Law, the Firſt Phænomenons, which are Produc'd, are thoſe of Mechanicks; the Explanation of which, from the preſent Lemma, if any One is deſirous to ſee, will be fully Inform'd from the Reverend and Ingenious Perſon before Refer'd to, in his Comments upon *Rohault*, and from the Celebrated Author of this Compoſition of Forces; It was indeed my Intention, according to the Method preſcrib'd in the Preface to theſe Philoſophical Tracts, to have gone thro' this, as well as the ſeveral other Parts of the Modern Philoſophy; but if we can have no Satisfaction in theſe Fundamental Maxims of it, there is no Reaſon to Expect the Arguings from them will be more Concluſive; We have likewiſe already conſider'd the Principles of Mechanicks, and ſhewn them to be Precarious or Falſe; and what the Preſent Account of them alledges depends upon much the ſame Principles, and all the Sagacity, which is Evident in it, is only this, Namely, the Collecting of ſeveral Caſes, and Uniting them into one, to wit, the Reſolution of the Diagonal Force into the Lateral; whereas thoſe ſeveral Caſes have been Prov'd to be wrongly Accounted for, and this Principle of the Reſolution of Forces to be wholly Chimerical.

Sir Iſ. Newt. Princ. Lex. 3. Coroll. 2.
Rohault. Chap. 14. Art. 9.
Preface to the Principles of Natural Philoſophy.

Concluſion upon the Whole.

§. 51. ALL therefore, which we ſhall farther do in the way of Confutation is only this, to conſider the Phyſical Account given of the Revolutions of the Heavenly Bodies, of the Primary and Secondary Planets in their Ellipſes, and the Comets in their Parabola's, as alſo of the Flux and Reflux of the Sea; we ſhall then Examine into the Doctrine of Hydroſtaticks, and into the Solutions concerning the Barometer, and if any Thing more is deſir'd of us, we are ready to do what lies in our Power, to ſatisfy all Impartial Inquirers into Nature, that the Principles, upon which they Proceed, in any Caſe Propos'd, are Equally inſufficient to the Explaining of it; The next Thing therefore, which will Engage our Enquiries, will be the Method of *Naſcent* and *Evaneſcent Reaſons*, which is the Baſis and Foundation of the *Phyſical Aſtronomy*.

CHAP. III.

Concerning the Method of Naſcent and Evaneſcent Reaſons.

The Firſt Lemma Explain'd. Sir Iſ. Newt. Princip. §. 1. Lem. 1. Lib. 1.

§. 1. THE Firſt Aſſertion, in the Method of Naſcent and Evaneſcent Reaſons, by which the whole following Philoſophy is Demonſtrated, is; That Quantities, or the Proportions or Reaſons of them, which in a Time given continually Tend to an Equality, and by that Means are capable of Approaching nearer to each other than according to any Difference Given, at Length become Equal.

IF it is deny'd, let their Laſt Difference be *D*, therefore they cannot come nearer to an Equality, than according to that Given Difference, contrary to the Hypotheſis, which ſuppoſes, that they may Approach nearer to each other than in any Given Difference.

This Lemma contrary to the Infinite Diviſibility of Extenſion.

§. 2. FIRST, In Reply to which we ſay, that, what Quantities are, ſhou'd be Determin'd, before we can Affirm any thing concerning them, or the Reaſons and Proportions of them; for if by Quantities are meant and intended Quantities in General, this Lemma will not be true; ſince it is thought, at leaſt by the Mathematicks now receiv'd, to be Demonſtrated, that, tho' the Curve of an Hyperbola and the Aſymptote of it continually Approach to Each other, yet they will never Meet; that, in the Extraction of the Root of 2, or of any other Surd or Ineffable Root, there is a Conſtant Approximation to Truth, but no Arriving at it; that, in Two Parallel Lines with a Perpendicular Drop't betwixt them, if Lines are drawn from any one Point, in either of the Parallel Lines, Tranverſe the Perpendicular, to the Oppoſite Parallel, they will never Exhauſt the Points of the Perpendicular, tho' they continually come nearer to the doing of it; and that the Nature of Quantities in General is, that they are Diviſible to Infinity; which if ſo, this Lemma cannot be true, becauſe it ſuppoſes the Laſt Difference to be nothing, or which is the ſame, that in all Quantities there is a Point, which is Indiviſible.

This Lemma depends upon the Preſent Abſtractions in Mathematicks, which are Arbitrary and Precarious.

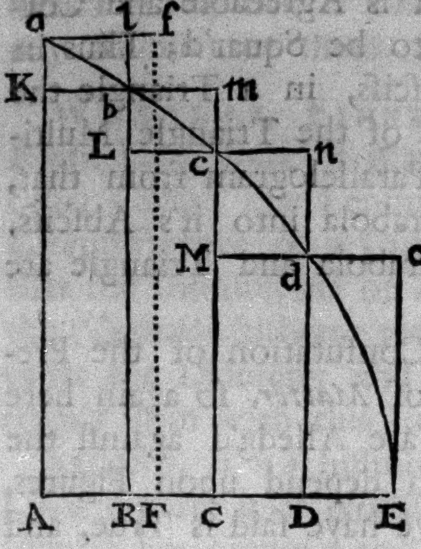
§. 3. SECOND, Another Argument againſt the Univerſal Truth of this Lemma is, that it Preſumes in Quantities it's own Abſtractions of them, that is, that all Quantity in Figures is Reſolved into Length, Breadth, and Thickneſs; whereas in the *Geometry* of *Solids*, or of *Matter*, and in the *Principles* of *Philoſophy*, *Chap.* 4. §. 11. *B.* 1. We have Endeavour'd to ſhew, that a Line of the ſame Length, or a Surface of the ſame Length and Breadth, or a Solid of the ſame Length, Breadth, and Thickneſs, may, and often really do's Expreſs Different Quantities; And yet this Lemma only conſiders the ſame Length, Breadth, or Depth, as Expreſſive of the ſame Quantity.

The Application of this Lemma to Curvilinear Figures not Defenſible.

§. 4. THIRD, The Preſent Lemma, by what follows, is meant of Right-Lin'd Figures, Inſcrib'd and Circumſcrib'd to a Curve, which by diminiſhing of them Infinitely will be at Length Equal to it; The Contrary of which we have Prov'd in the ſaid *Principles* and *Geometry*, to wit, that no Part of any Right Line, Inſcrib'd or Circumſcrib'd to a Curve, can ever be a Meaſure of it, and into which we ſhall farther Examine in the Succeeding Sections.

The Second Lemma Explain'd. Sir Iſ. Newt. Princip. §. 1. Lem. 2. Lib. 1.

§. 5. The Second Lemma or Aſſertion in this Philoſophy, Previous to it's Demonſtrations, is; That if in any Figure, as *AacE*, there ſhou'd be Inſcribed as many Parallelograms, as we pleaſe, *Ab*, *Bc*, *Cd*, &c. contain'd under Equal Baſes *AB*, *BC*, *CD*, &c. and Sides *Bb*, *Cc*, *Dd*, &c. Parallel to the Side of the Figure *Aa*, and the Parallelograms *aKbl*, *bLcm*, *cMdn*, &c. ſhou'd be Fill'd up or Compleated, and afterwards the Latitude of theſe Parallelograms ſhou'd be Diminiſh'd, and the Number of them Increaſed to Infinity; What then? It then peremptorily Affirms and Pronounces, That the Laſt or Ultimate Reaſons or Proportions, which the Inſcrib'd Figure *AKbLcMdD*, the Circumſcrib'd *AalbmcndoE*, and the Curvilinear *AabcdE* obtain to each other, are thoſe of an Equality.



Because the Difference of the Figure Inſcrib'd and Circumſcrib'd is the Sum of the Parallelograms *Kl* + *Lm* + *Mn* + *Do*, that is, as their Baſes are all Equal, the Rectangle under the Baſis *Kb* and the Sum of the Altitudes *Aa* will be Equal to ſuch Difference, namely, the Rectangle *ABla*, but this Rectangle is Leſs than any given, by the Latitude *AB* being Diminiſh'd to Infinity, and therefore, according to the Firſt Lemma, the Figure Inſcrib'd and Circumſcrib'd, and much more the Curvilinear Figure, which is Intermediate to them, will be at Length Equal. *Q. E. D.*

This Demonſtration not Valid, becauſe it either ſuppoſes what is to be Prov'd, or elſe it ſuppoſes a Contradiction.

§. 6. But this Demonſtration fails upon ſeveral Accounts; First, becauſe the Nature of Infinity is not ſo clearly and fully Explain'd, that we ſhou'd be certain, that *AalB*, upon an Infinite Diminution, will be Equal to Nothing, or that the Laſt Difference will be ſo; for to ſay, according to Lemma the Firſt, that the Laſt Difference is Equal to Nothing, becauſe the Quantities are ſuppos'd to Approach nearer to each other, than in any Given Difference, is either to Affirm, that the Laſt Difference is Equal to Nothing, becauſe it is ſuppos'd not to be Something, or elſe it is to Affirm, that the Laſt Difference is Equal to Nothing, becauſe there is no End of any Finite or Given Difference; If the Firſt is Intended, it is Proving a Thing by ſuppoſing the Thing to be Prov'd; If the Laſt, it is a Contradiction; ſince, if there is no End of the Finite Difference, there cannot be a Laſt Difference, nor can that Laſt Difference be Equal to Nothing.

This Demonſtration Leſs Certain, becauſe the Abſtractions of Quantity, on which it proceeds, are not True.

§. 7. Second, As *AalB* is not Evidenc'd to be Equal to Nothing, even upon the Suppoſition of the Preſent Abſtractions in Mathematicks, ſo it will be much leſs Prov'd, if we ſhow, that the Quantities, hitherto Receiv'd in that Science, and Affirm'd in this Lemma, are falſly Stated and Defin'd; For, in this Demonſtration, it is ſuppos'd, that the Lines, *AE*, *Aa*, whether Apply'd to the Curve *aE*, or to the Parallelograms, whoſe Baſes are *AB*, *BC*, *CD*, *DE*, and the Sides Meaſur'd by Portions of the Line *aA*, are the ſame; whereas it has been already Demonſtrated in the *Principles of Philoſophy*, *Chap.* 4. §. 11. *B.* 1, and in the *Geometry of Solids*, or of *Matter*, that Lines, which are the ſame in Reſpect of their Length, Receive Different Values, and are Quantities Infinitely Different in their Nature; Thus, if *aE* is the Curve of a Parabola, *aA* will be a Line of which *AE* is as it's Square Root, if of a Cubical Paraboloeid, *AE* will be as it's Cube-Root, if of a Biquadratical Paraboloeid, as it's Biſquare-Root, *&c*; And conſequently, if *AE* is Multiply'd into *aA*, both of them being conſider'd as Simple Lengths, a Common Parallelogram will Ariſe of the ſame Nature and Conſtitution with thoſe, which are Inſcrib'd and Circumſcrib'd to the Curve, where the bare Lengths of the Lines, and the Multiplication of them only Enter into the Compoſition of the Figure; but if *AE* is the Ordinate of a Parabola, it will be as the Square-Root of *aA*, and Multiply'd into it, a Parallelogram will Ariſe, which, in Reſpect of the Former, will be as the Root of *aA* to *AE*, which was before as *aA*; If *AE* is the Ordinate of a Cubical Paraboloeid, it will be as the Cube-Root of *aA*, and Multiply'd into it, will form a Parallelogram, which, in Reſpect of the Firſt, will be as the Cube-Root of *aA* to *AE*, which was originally as *aA*, &c; From whence it is Evident, that the Reaſoning in this Lemma cannot be juſt, which Imagines, that the Parallelograms Inſcrib'd or Circumſcrib'd to the Curve are of the ſame Nature and

Conſtitution with thoſe, which are form'd from the Multiplication of the Parts of the Lines, conſider'd not as bare Lengths, but as Abſciſſes and Ordinates of ſuch Curves; From whence it follows, that when the Square of a Curve Figure is Compar'd with the Area of it, ſuch a Square is to be made uſe of, which is Agreeable and Correſpondent to the Nature of the Figure, which is Propos'd to be Squar'd; Thus in the Parabola the Ordinate is as the Square-Root of the Abſciſs, in a Triangle the Ordinate is as the Abſciſs, and conſequently, the Ordinate of the Triangle Multiply'd into it's Abſciſs, will Produce a Different Square or Parallelogram from that, which is form'd from Multiplying the Ordinate of the Parabola into it's Abſciſs, altho', as to Length, the Ordinates and Abſciſſes of the Parabola and Triangle are Equal.

Geometriæ Solidorum ſive Materiæ, Pars. 1.

We have taken the Liberty to add this, not only in Confutation of the Preſent Lemma, but as we had before done in our *Geometry* of *Matter*, ſo again here to ſhew of what little Force thoſe Arguments are, which are Alledg'd againſt the *Square* of the *Circle* Propos'd in that *Geometry*, and which depend upon Figures, which are Inſcrib'd or Circumſcrib'd to it; ſince, if what we have ſaid is True, and ſince all Figures, which are Inſcrib'd or Circumſcrib'd, are Reſolv'd into Triangles, whoſe Square will be that of a Triangle, and farther, ſince the Square of a Curve is not of the ſame Nature or Conſtitution with the Square of a Triangle, it is Manifeſt, that no Arguments can Affect us, which are deriv'd from ſuch Ways of Reaſoning.

The Third Lemma Explain'd, Sir Iſ. Newt. Princip. §. 1. Lem. 3. Lib. 1.

§. 8. The Third Aſſertion in this Method of Naſcent and Evaneſcent Reaſons is, That the ſame Ultimate Reaſons, before-mention'd, are likewiſe thoſe of Equality, even where the Latitudes of the Parallelograms *AB*, *BC*, *CD*, *DE* are Unequal, and where they are all Diminiſh'd to Infinity.

For let *AF* be Equal to the Greateſt Latitude, and the Parallelogram *FAaf* Compleated, This will be Greater than the Difference of the Inſcrib'd and Circumſcrib'd Figure *ABla*, but it's Latitude *AF* being Diminiſh'd to Infinity, it will become Leſs than any Given Rectangle.

From whence theſe Corollaries are Drawn;

1. That the Ultimate Sum of the Evaneſcent Parallelograms Coincides with the Curvilineal Figure.

2. And much more the Rectilineal Figure, which is Comprehended within the Chords of the Evaneſcent Arcs *ab*, *bc*, *cd*, at laſt Coincides with the Curvilineal.

3. As alſo the Rectilineal Figure, which is Circumſcrib'd by the Tangents of the ſame Arcs.

4. And therefore theſe Ultimate Figures, as to the Perimeters *acE*, are not Rectilineal, but the Curvilineal Limits of Rectilineal Figures.

The Deſign of this Lemma farther Explain'd, and the Truth of it Examin'd.

§. 9. As to the Deſign of this Lemma, it ſeems to be nothing more than to make that Univerſal, which was Partially Demonſtrated before, ſince *AE* was only conſider'd, as divided into Equal Parts; Let us therefore now ſuppoſe it to be Diſtinguiſh'd into Unequal, and the Caſe in Reſpect of the Ultimate Reaſons will be the ſame, becauſe, if *AFfa* is Greater than *ABla*, and conſequently, the Difference *Kf* Greater than *Kl*, which upon an Infinite Diminution Vaniſhes, it is Manifeſt, that any Difference, whoſe Latitude is Equal to or Leſs than *AB* or *AF*, will alſo be Exhauſted by ſuch an Infinite Diminution, and *Vice Verſâ*. What therefore has been Objected againſt the Preceding Lemma will be Equally Valid againſt This; And moreover we may ſay, that, if *FA* upon an Infinite Diminution is reduced to Nothing, as well as *BA*, either there are an Equal Number of Parts in each, or elſe Infinity is an Equivocal Term, and is thought able to deſtroy Quantities, whoſe Number of Parts is Different; if yet Infinity is Affirm'd to be the ſame Thing, and not an Undetermin'd and Wandering Notion, and if the Number of Parts in *AF* and *AB* are the ſame, all the Difference, which can be betwixt them, muſt be reſign'd to the Difference of Magnitude in the Parts; If the Firſt is defended, That the Number of Parts is Equal, that is Impoſſible, unleſs the Parts are of a Different Magnitude; If the Second, That Infinity is ſomething Undetermin'd, we don't know what, Any Demonſtrations from it will be as Juſt as the Idea is, that is, will Signify Nothing; If the Third is Profeſs'd and Maintain'd, That the Ultimate Part of *AF* is Greater than that of *AB*, they cannot be both Equal, namely, to Nothing.

§. 10.

§. 10. IF therefore the Preceding Lemmas are not Certain or True, the Corollaries from them cannot be. It is, notwithſtanding, ſaid *Corol.* 4, That the Ultimate Figures (as to their Perimeters acE) are not Rectilineal, but Curvilineal Limits of Rectilineal Figures, that is aE is a Curve Line, and not Compounded of Right ones, or any Number of them.

Corollary the Fourth particularly Inquir'd into, and the Nature of Curve Lin'd Figures Conſider'd.

WHEREAS, FIRST, if ab Infinitely Diminiſh'd is not the Portion of any Right Line, ſince it may be as well conceiv'd to be a Part of a Circular, as any other Curve, this Lemma, and the Corollary from it, will Equally prove, that the Circumference of a Circle is not a Polygone of an Infinite Number of Sides, and that the Infiniteſima of ab is not a Right Line; upon which, notwithſtanding, all the Methods hitherto receiv'd of *Squareing* the *Circle*, by finding the Proportion betwixt the Diameter and Circumference do depend, and which Methods, we ſhall readily Join with this Lemma, in Refuſing and Condemning.

SECOND, If ab Infinitely Diminiſh'd is a Curve, and not any Portion of a Right-Lin'd Figure, it is Nothing according to this Reaſoning, for aK, al Diminiſh'd to Infinity are ſuppos'd to be Nothing, what therefore the Point a can be more is not Conceivable; If a is Something, the Queſtion will be, whether it is the Part of a Curve Line, or of a Right one, aK is common to both Figures, that is, to $Kalb$, and Kab, and therefore at length the Inquiry will be, whether a is a Part of the Curve ab, or of the Right Line al; if the Laſt, it is Evident, that a in the Curve ab is a certain Portion of the Right Line al, which yet is here deny'd; If the Firſt, it is Prov'd by Affirming it, and cannot be made Clearer, or more Demonſtrable, by Lines al or Kb, Circumſcrib'd or Inſcrib'd to it, which it is own'd do not any ways Belong or Appertain to it, nor are any the leaſt Portion of it.

THIRD, It is not Evinced, but a, b, c, d, &c. may be Parts of Right-Lin'd Figures, ſince the Point at a is the Concourſe of Two Right Lines Ka, la, which Concourſe cannot produce Curveneſs, but may the Rectitude of each Line Expreſs'd in the ſame Point, and the like may be Affirm'd of b, c, d, &c; that is, there is no Curvity in the Nature of each Point, from the manner of it's Production; But if the Curvity proceeds from the Poſition of the Points in Reſpect of aA, that will not prove the Points themſelves are Curvilineal, or that they may not be of a Rectilineal Conſtitution, we only here Argue with this Philoſophy in it's own Way, becauſe we have ſhewn, that the Parts of Curve Lines are Curves, and are not Reſolvible into Right ones.

FOURTH, If it cou'd be Prov'd, that a, b, c, d, &c. were Curvilineal Parts of aE, by this way of Reaſoning; according to the *Geometry* of *Solids*, they may be of the ſame Nature with Rectilineal Parts, ſuppoſing their Velocities to be alike.

Geometriæ Solidorum ſive Materiæ, Pars. 1.

FIFTH, Beſides all which, ſince AaE may poſſibly be of Different Dimenſions, as to Length, Breadth, and Depth, from the Parallelograms Inſcrib'd and Circumſcrib'd, the Compariſon betwixt them can ſignify no more to the Demonſtrating any Thing from it, than if we ſhou'd compare a Line with a Surface, or that with a Solid, according to the ſame *Geometry*.

LASTLY, The Nature of a Curve, whether of a Circle or any other, when the Abſciſſes and Ordinates are ſuppos'd to Generate it, is Compounded of the Terminations of the Joint Velocities of aK and Kb, as the Diagonal of a Square, or a Parallelogram, is Compounded of the Terminations of the Velocities of the Parts of the Side in Conjunction with thoſe of it's Ordinates; Thus, if aA is the Side of a Square, and aE is ſuppos'd to be the Diagonal of it, whilſt a proceeds with the Velocity of 1 to K, K proceeds with the ſame Velocity of 1 to b, and Lodges or Expreſſes the Firſt Point in the Diagonal, if aK and Kb are Imagin'd to be Infinitely Small; and in like manner, the Second, Third, Fourth Points, *&c.* from a Velocity of 2 and 2, 3 and 3, 4 and 4, *&c.* are produced in the Diagonal, till the whole is form'd.

FROM whence it is Manifeſt, that each Point in the Diagonal is only the Limit or Termination of both the Velocities after they are actually Perform'd, and therefore the Diagonal, which this Philoſophy Propoſes, and which we have Confuted, is not made up of the ſame Forces Conjoin'd, which are ſeparately Deſcrib'd in the Sides of the Parallelogram, ſince the Diagonal is no other than a Termination of thoſe Forces, and is not in any Manner or Way of Conſidering an Union or Conjunction of them.

Second, From this likewiſe it is plain, that the Diagonal is Incommenſurable with the Side of the Square; Becauſe the bare Termination of Forces cannot be Meaſur'd by thoſe Forces, or the Contrary; Thus *b* is the Firſt Point from *a* of the Diagonal, which being only a Termination of the Velocities *aK*, *Kb* is no ways Capable of a Compariſon with them, no more than a Quieſcent Point is with an Actual Force, which it Bounds and Determines.

In like Manner, if *aA* is the Abſciſs of a Parabola, *b* the Point in the Parabolick Curve will be the Limit or Termination of the Velocities *aK*, *Kb*, and the ſame Reaſoning will obtain in Reſpect of the Points *c*, *d*, &c, which will be the Terms or Boundaries of the ſeveral Velocities Expreſs'd by the Abſciſſes and Ordinates, and, as before was ſaid of the Diagonal of the Square, will be Incommenſurable with them.

Dr. Wallis Arithmetica Infinitorum. Geometria Solidorum ſive Materiæ.

We ſhall therefore only farther Add, that ſince in the Triangle, where the Velocities of the Abſciſs and the Ordinate are Equal, or as Equal Velocities, the Diagonal is a Right Line, and ſince in the Parabola and in Paraboloeids, where the Velocity in the Abſciſs is Greater, and in the Ordinates Leſs, the Diagonal is a Curve, which is Concave to the Abſciſs, and ſince in the Complements to the Parabola or Paraboloeids *alb*, where the Velocity of the Abſciſs is Leſs, and that of the Ordinate Greater, the Diagonal is a Curve, which is Convex to the Abſciſs, we may from hence Form a juſt Idea of the Nature of Curves; In which, where the Velocities are Greater in the Abſciſs, and Leſs in the Ordinates, the Curve is Leſs Repell'd from the Abſciſs, and Approaches or is Attracted towards it, by how much it's Force is Greater, and that of the Ordinate Leſs, which hinders it's Approach; On the Contrary, where the Force is Leſs in the Abſciſs, and Greater in the Ordinate, the Curve is Thruſt and Protruded from it, or is Leſs Attracted to it, by how much the Force, which Protrudes is Greater, and the Force, which Acts or Directs it, Leſs; Thus *aE* Converges towards *aA*, and Diverges from *al*. And if we Take any Abſciſs whatſoever, and Divide it According to the Square Numbers 1. 4. 9. 16. 25, *&c.* and Place Ordinates at the ſeveral Diviſions, According to the Square-Roots of thoſe Numbers, namely, a Series of Natural ones, 1, 2, 3, 4, 5, *&c.* we ſhall find the Curve of the Parabola, which Connects the Extremities of the Ordinates, to Converge to the Abſciſs, but if, on the Contrary, the Portions of the Abſciſs are 1, 2, 3, 4, 5, *&c*, and the Ordinates 1. 4. 9. 16. 25, *&c.* the Curve, which Connects Them, will Diverge from it; The ſame may be ſaid of an Abſciſs Divided Cubically, Biquadratically, *&c.* and where the Ordinates are as the Roots of thoſe Cubes or Bi-Squares, or where the Portions of the Abſciſs are as the Roots, and the Ordinates as the Cubes or Bi-Squares, for in the Firſt Caſe the Curve of the Paraboloeid will Converge to the Abſciſs, and in the Laſt Diverge from it; Hence alſo, if we Compare the Space, Produc'd by theſe Ordinates, with that of Paraboloeids and the Complements of them, it will Appear, that Different Spaces may be Effected by the ſame Forces, as we before ſhew'd in the *Geometry* of *Solids*, that the ſame Spaces might be Conſtituted from Different ones.

From this General Theorem it ſeems Plain and Evident, if *aE* is the Portion of a Circle, and *aA* the Radius of it, ſince the Curve in this Caſe Converges to the Abſciſs, that it is in the Number of Paraboloeids, and which, in the *Geometry* of *Solids*, or of *Matter*, we have Endeavour'd to ſhew is a Biquadratical one, and which very well agrees with the General Theorem mention'd.

For let *aK*, and the ſeveral Parts of *aA*, be Repreſented by Numbers in an Arithmetical Progreſſion to Infinity, the Ordinates in the Parabola will be as the Roots of thoſe Numbers, and in the Biquadratical Paraboloeid, as the Roots of the Roots of them; from whence it will follow, that there is a much Greater Protruſion of the Limits of the Velocities from the Abſciſs in the Firſt Caſe than in the Laſt, and conſequently, that the Curve will Approach nearer to a Convexity in the one Inſtance than the other; which is Manifeſt, ſince the Parabola comes nearer to a Right Line, than a Circle do's, or, which is the ſame, a Circle is more Concave to the Abſciſs than the Parabola, but a Right Line is Firſt to be Arriv'd at, before a Convexity to the Abſciſs can be Produced; Thus the $\sqrt{1}$, $\sqrt{2}$, $\sqrt{3}$, $\sqrt{4}$, *&c.* which are the Ordinates of a Parabola, are in a nearer Proportion to 1, 2, 3, 4, *&c.* which wou'd make the Ordinates of a Triangle, and the Diagonal a Right Line, than the $\sqrt{\sqrt{1}}$, $\sqrt{\sqrt{2}}$, $\sqrt{\sqrt{3}}$, $\sqrt{\sqrt{4}}$, *&c.* which are the Ordinates of a Circle.

Geometriæ Solidorum ſive Materiæ; Pars. 2.

FROM what has been ſaid it is likewiſe Evident, that the *Hyperbola* is alſo in the Number of *Paraboloeids*, but the Proportion, which it has to it's Rectangle, we ſhall Leave to others to Determine, tho' we have it Aſcertain'd in Writings by us, upon the ſame Principles, by which we have *Squar'd* the *Circle*.

A Second Way of Conſidering Curves, and the Generation of Them.

§. 11. HAVING thus far Conſider'd the Nature of Curves, in Reſpect to their Ordinates and Abſciſſes, and their being only Limits or Terminations of their Velocities; we ſhall now ſhew, how they may be Conſider'd in another Way, that is, by the Generation of them from their Centers, as in the *Circle*, or from their Focus's, as in the *Ellipſis*, the *Parabola*, and *Hyperbola*.

As to the Circle, it's Geneſis is Manifeſt, by the Revolution of a Line upon a Center; but the Queſtion, which lies in the *Doctrine* of *Velocities*, or the *Geometry* of *Solids*, is, what the Nature of ſuch a Curve is, which cannot be any other than that of a Right Line; For, if we ſuppoſe ſeveral Circles to be drawn from the ſame Center, their Circumferences will be to each other, as their Radius's, by the Extremities of which they are Deſcrib'd; that is, they will be as Right Lines, and differ Nothing from them, but in their being bent into a Poſition, in which all the Points of the Line are Equidiſtant from the Center, whereas a Right one, as the Radius, has it's Points diſpos'd in a Direct Receſſion from it.

BESIDES, the Velocities in each Circumference are Equable, without any Acceleration or Retarding of them in the ſame Circumference, which is likewiſe the Nature and Property of a Right Line, which is Produc'd by the Equable Fluxion of a Point.

AND in Different Circumferences, where the Velocities are Greater in Proportion to the Greater Lengths of the Radius, the ſame Tenour of Velocity is Preſerv'd, whilſt a Larger Space is Perform'd by a Larger Velocity in the ſame Time, that a Leſſer Space is Perform'd by a Leſſer Velocity; For that, which makes an Alteration from a Right Line into a Curve, is a Different Velocity in the ſame Space and the ſame Time, according to the aforeſaid *Geometry* of *Solids*.

FROM whence it is Apparent, FIRST, that the Circumference of a Circle, Conſider'd in this way of Generation, is perfectly Different from that, which is Produced by the Termination of the Forces Expreſs'd in the Sines and Vers'd Sines of it, (the Laſt of which are it's Abſciſſes, and the Firſt it's Ordinates) ſince the Circumference in the one Caſe is no more than a Right Line, or one Kind of Force, continually Bent, and in the other a Termination of Forces, which continually Differ.

SECOND, The ſame Curve Line to Appearance may therefore in Reality receive very Different Values and Denominations, and be as Diſtinct from what it Appears, as any other Quantity whatſoever, and conſequently, the ſame *Circle*; ſince where the Circumference of it obtains the Nature of a Right Line, it will be a *Plane* Figure, and where that of a Curve, or of a Termination of Forces, which continually Vary, it will be a *Solid* one.

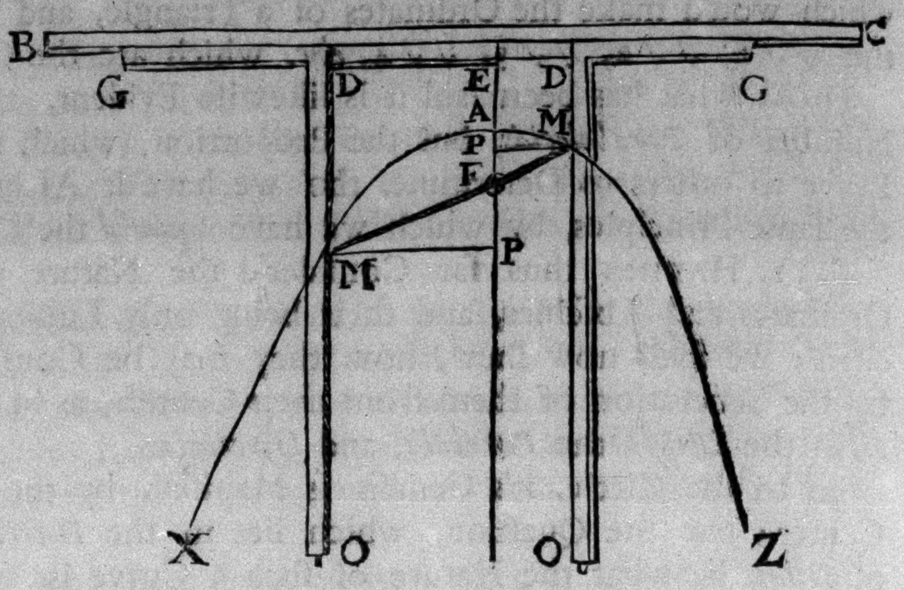
THIRD, If we then Conſider a *Circle* as a *Plane* Figure, the *Square* of it will be as Eaſy, as of any other *Plane* Figure we can Mention; becauſe there is nothing elſe Requir'd, than to make the Radius the Perpendicular of a Right-Angled Triangle, and the Circumference the Baſis of it, which will be half of the Rectangle under the ſame Radius and Baſis, and Equal to the *Circle*; nor would there be any Greater Reaſon to find out the Proportion betwixt the Baſis, *i. e.* the Circumference of the *Circle*, and it's Radius, in order to Obtain the *Square* of the *Circle*, than betwixt the Two Sides of any Triangle, in order to Aſcertain the *Square* of it; for to find the *Square* of the *Circle* is to Aſſign a certain Rectilineal Figure, to which the Area of the *Circle* has a Known Proportion, which is done as Above.

Pardies Geometriæ Elementa, Lib. 4. Art. 24. & 31.

IF the *Circle* is not Conſider'd as a *Plane* Figure, but a *Solid*, we have Endeavour'd to Determine it's Proportion to the *Square* in the *Geometry* of *Solids*, or of *Matter*, namely, that it is as 4 to 5, and is no other than a *Biquadratical Paraboloeid*.

L'Ho'pital:
Sections
Conique,
Livr. 1.
Definit. 1.
Livr. 2. Def. 1.
Livr. 3. Def. 1.

As to the *Parabola*, the Generation of it is Perform'd by ſuppoſing a Rule BC, upon which the Square GDO is mov'd, whoſe Side GD is carry'd along the Rule BC, from E towards B, the other Side of the Square DO has a Line affixt to it, one of whoſe Extremities is faſten'd at O, and the other in ſome Point or other of the Plane, in which it Moves, as F; Let a Style be held always at M, the Point where the Line Tears off from the Side of the Square DO by it's Motion from F, and it will Deſcribe the Parabola AMX; By the ſame Methods AMZ will be likewiſe Deſcrib'd by Inverting the Square towards C, and Moving it that way from the ſame Focus F; And ſince the Deſcriptions of the Ellipſis and Hyperbola depend upon the like Compound Motions, which are Refer'd in ſome Meaſure or other to their Focus's, as their Centers, it will not be Neceſſary to conſider, in this General Idea of the Nature of Curves, the particular Circumſtances of thoſe Deſcriptions, Eſpecially, as the *Circle* and the *Parabola* are the Figures, which we at preſent are Deſirous to Examine; The *Square* of the Laſt being Confeſs'd, and *That* of the Firſt being here Defended.



In this Generation of the *Parabola* it is therefore Evident, that it Differs from that, which Reſults from a bare Termination of the Velocities Expreſs'd by the Abſciſſes and their Ordinates; ſince the Generation of it by a Line, and the Mediation of a Square, and the Focus, is by an Actual Velocity, whereas, when it is Produc'd by a Termination of Actual Forces, in the Abſciſſes and Ordinates, it is made up of ſo many Quieſcent Points, as there are Terminations of ſuch Forces; from whence it will follow, that the Parabola, in the one Caſe, is of a Different Nature from that in the other, unleſs Quieſcence and an Actual Velocity are the ſame.

Second, Suppoſing the Forces were Actual in both the Deſcriptions, yet, ſince AMX is Deſcrib'd from the Focus F, by FA, FM, FX, as the Circle from a Center, they ſo far Agree, and all the Difference ſeems to be, that whilſt the Radius of Deſcription continues Immutable in the Circle, in the Parabola it as conſtantly Varies, from FA to FX.

But the Variation of the Length of the Radius does not hinder the Equableneſs of it's Motion, or at leaſt it's being Equably Increas'd; ſince in Concentrical Circles the Radius's may be of Different Lengths, and the Swiftneſs of their Deſcription Different, and yet the Velocities in the ſeveral Circumferences of the ſame Nature with the Equable ones in Right Lines, according to what has been before obſerv'd; And that this is the Caſe of the Changing Radius's of the Parabola from the ſame Focus is Plain.

For, if we ſuppoſe AP to be the Axis of a Cone, on the Surface of which the Parabola XAZ is drawn, the Point A in the Vertex of it may be Deſcrib'd by FA, the Radius of a Circle Parallel to the Baſis of the Cone, and whoſe Center is in the Axis of the Cone AP; and by the ſame Methods FM, FX, or any other Intermediate Lines from the Focus, may be Repreſented by Radius's of the ſame Lengths, whoſe Circles are Parallel to the Baſis of the Cone, and whoſe Centers lie in the Axis of it; For if, for Inſtance, PM is Imagin'd Equal to FM, it will be the ſame Thing, if we take Different Points P and F, and make the one the Center of a Circle Parallel to the Baſis of the Cone, and the other the Focus of the Parabola, becauſe in both Caſes the Point M has the ſame Diſtance from the Axis of the Cone; And conſequently, if we make all the ſeveral Centers P of the Circles, Parallel to the Baſis of the Cone, unite and fall in with F, and the Circles, which were Parallel to the Baſis, Coincide with the Plane of the Parabola, they will then become one Focus, and the Radius's of the Parallel Circles will be Radius's of the Parabola drawn from the ſaid Focus.

If therefore theſe Parallel Circles are all Preſs'd into one and the ſame Plane, they will become Concentrical, and the Curve of the Parabola will be Reſolv'd into a Line of the ſame kind with Circumferences Deſcrib'd by the Radius's of them, and conſeqnently of the ſame Conſtitution with Right Lines, Deſcrib'd by Equable Velocities; From whence it will Enſue, that the Parabola, by this way of Deſcription, is a Plane Figure, being Reducible to Triangles of Different Heights, as the Circle is to thoſe of the ſame Height, and therefore has the Nature of all other Triangles.

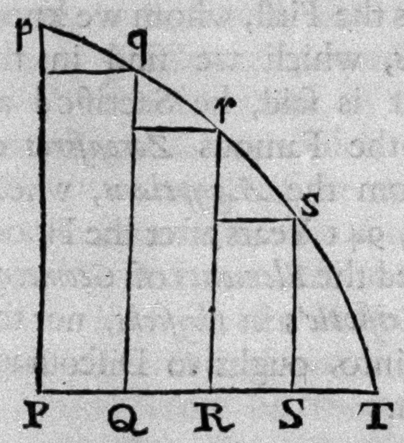
On the Contrary, if the Forces of the Abſciſs and Ordinates are made uſe of to determine the Parabola, the Curve will not be Conſider'd, as a Right Line, but every Point of it will Vary in it's Velocity, or the Termination of it, according to the Proportion of the Forces in the Abſciſſes and Ordinates, with which they End or are Concluded; and conſequently both the Curve and the Plane, which it Comprehends, will be of a Different Nature, and of Different Dimenſions, than when the one is conſider'd as a Right Line, and the other as a Triangle.

Having mention'd the Reduction of a Parabola to Portions of Concentrical Circles, we ſhall here ſhew, how we may Reduce the Angles of Contact to the Aſymptotes of an Hyperbola, albeit, they have been hitherto Miſtaken by Mathematicians for Diſtinct Arguments to Prove the Infinite Diviſibility of Extenſion, whereas they are in Effect the ſame.

For all the Circles, which are Deſcrib'd by the Ordinates of the Hyperbola, and which conſtitute the Hyperbolick Cone, ſince they are Parallel to ſo many Circles in the Baſis, may be Expreſs'd in the Baſis, and therefore will become Concentrical Circles; and as the Baſis, by ſuch Repeated Expreſſions of Circles in it, will be Equal to the Cone, that is, a Plane to a Solid, ſo alſo will the Circumferences be Concentrical, and all lie in a Common and Plane Surface; but every Point in the Aſymptote may be likewiſe Expreſs'd in the Baſis, at the ſame Diſtance from each Circumference in it, which it obſerves in the Aſymptote from the Circles in the Hyperbolick Cone, and at the ſame Time may Touch each Circle; ſince the Point in the Aſymptote is Trajected, by Right or Tangent Lines, thro' each Point of the Hyperbola, whoſe Circumferences are Deſcrib'd in the Baſis; and the whole Figure, by ſuch a Diſpoſition, will amount to the ſame with a Tangent, and the Various Circles annext to it, by whoſe Intervention the Angles of Contact are made.

The Fourth Lemma Explain'd.
Sir Iſ. Newt. Princip. Lem. 4. Lib. 1. §. 1.
See alſo Fig. §. 5.

§. 12. The Fourth Lemma is, That if, in Two Figures *AacE*, *PprT*, there ſhou'd be Two Series of Parallelograms Inſcrib'd, as before, and the Number of both ſhou'd be the ſame, and where the Latitudes are Diminiſh'd to Infinity the Ultimate Reaſons of the Parallelograms in one Figure to the Parallelograms in the other, each to each, ſhou'd be the ſame, it is Pronounc'd, That the Two Figures *AacE*, *PprT*, are to one another in that ſame Reaſon.



This Lemma ſo evidently depends upon the Former, that there is not the leaſt Occaſion to conſider it.

The Fifth Lemma Conſider'd and Examin'd.
Sir Iſ. Newt. Princip. Lem. 5. Lib. 1. §. 1.

§. 13. The Fifth Lemma is, That all the Sides of Similar Figures, which Anſwer to each other or are Homologous, are Proportional, as well Curvilineal as Rectilineal, and their Areas are in a Duplicate Reaſon of their Sides.

That Curvilineal Figures obtain this Property is upon the Suppoſition, that, according to the Preceding Lemmas, Right-Lin'd Figures are Ultimately Reſolv'd into Curvilineal ones, or the Contrary, which has not been Prov'd;

Elem. 6. Prop. 4. 19. 20.

Granting yet this, it is not Evident, that the Homologous Sides of Rectilineal Figures are Proportional, unleſs upon the Abſtractions and Demonſtrations of *Euclid*, in which the Length of the Line is only Conſider'd, and ſuppoſed to be one Conſtant and Invariable Idea; Thus, if I perceive Two Triangles to be Similar, I Judge them to be ſo upon the Equality of the Angles, which Equality is Prov'd, upon the Hypotheſis of one conſtant Uniform Space Abſtracted by the Mind, whereas if Space is not Uniform, and that Abſtraction is not Juſt, the Demonſtration will be in Proportion Defective; And ſince we have ſhewn, in the *Geometry* of *Solids*, and in the

Firſt Part of the *Principles* of *Natural Philoſophy*, that ſuch Abſtractions of a Simple and Fixt Space are not Juſt, neither this Propoſition, nor any other in all *Euclid*, will be Univerſally True.

We do not yet here Affirm, that this Propoſition as well as the others, in the *Geometer* Mention'd, are Abſolutely Falſe, it is Confeſs'd they are True, and that the Three Angles of a Triangle are Equal to Two Right ones, upon the Suppoſition of a Fixt, Abſtracted, and Invariable Space, but ſuch a Space we ſay is Arbitrary, and in Terms deny to Be, or to Exiſt in Nature.

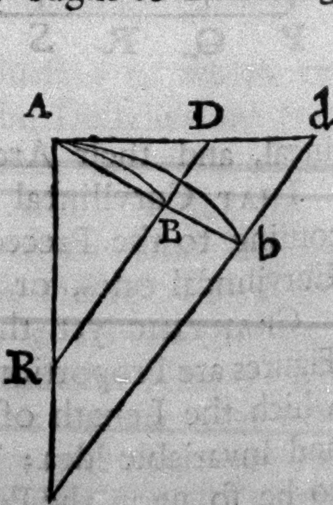
Nor by ſuch an Aſſertion do we deſtroy *Trigonometry*, and all the *Mathematick Sciences*, which are Built upon it; Since Abſtracted Space, which only Conſiſts of Length, Breadth, and Thickneſs, is a ſufficient Meaſure for all the Uſes of Life, whether in *Geometry*, properly ſo call'd, or in *Navigation*, *Fortifying*, or *Aſtronomy*; For, in all theſe Sciences, the Nature of the Meaſure is not Requir'd, but ſome fixt Standard or other of it; Thus in finding the Area or Contents of a Field, or of this Room, in which I write, I can Meaſure it by Walking over the Sides of it, that is, by certain Portions of Space, which I Mark out, or by a Foot of Wood, Braſs, or Iron, or any other Material Being; in which yet I conſider nothing, but the Abſtracted Length of the Meaſure, without Examining into the Nature of it, whether it be Real Space, Wood, Braſs, or Iron.

And this is the Caſe of *Mathematicks* in General, which Imagines nothing more than the Abſtracted Lengths, or Breadths, or Depths, of Things without Conſidering the Intrinſick Nature and Conſtitution of them, which, notwithſtanding, ought to be a Rule of the Mind's Abſtractions, and not it's own Will and Pleaſure; The *Mathematicks* therefore, which we propoſe of *Solids* and *Matter*, we cannot but think are Conformable to the Firſt, and what has been hitherto advanced in that Knwoledge nothing, more than the Reſult of the Latter; That is, We in our Mathematick Abſtractions take Nature for our Guide, whereas the *Mathematicians*, who have Wrote before Us, make their own Arbitrary Will and Pleaſure their Conductors; And upon this Iſſue we dare put our whole Reaſonings in that Science; For if our Abſtractions are ſuitable to Nature, as that will always Stand, the Wills and Arbitrary Fancies of Men muſt, ſome time or other, ſubmit to it, if they are not, we ſhall readily reſign our own Sentiments to thoſe who have Preceded us on theſe Subjects; Seeing, what we Intend in theſe Principles, is only to over-turn if Poſſible, and Demoliſh thoſe Structures, which ſome fond Perſons have Raiſed in their own Imaginations, either in Reſpect of *Mathematicks* or *Aſtronomy*, without any Warrant from the Reality of Beings, as they Exiſt; And altho' *Pythagoras* was the Firſt, whom we know of, who Introduc'd theſe Abſtractions amongſt the *Grecians*, which we find in the Elements of *Euclid*, for the *47th Prop. B. 1.* of which, it is ſaid, he Sacrific'd an Hecatomb, and altho' he Deriv'd theſe Abſtractions from the Famous *Zoroaſtres* of *Bactria*, whoſe Scholar he is thought to have been, and from the *Ægyptians*, whoſe Prince *Meres* the *Philoſopher*, the 28th in Deſcent from *Meſraim*, 941 Years after the Flood, and 675 before the Firſt *Olympiad*, is Affirm'd to have Invented the *Elements* of *Geometry*, yet neither His Authority nor Theirs in *Mathematicks*, nor *Ariſtotle*'s in *Phyſicks*, nor the preſent *Philoſopher*'s in Both, whom we are now Inquiring into, ought to Diſcourage or Hinder any Impartial Reſearches after Truth and Reaſon.

Dr. Prideaux's Connection, &c. Eratoſthenes's Table in Dr. Cumberland on Sanchoniatho's Phænician Hiſtory.

The Sixth Lemma Conſider'd. Sir Iſ. Newt. Lem. 6. Lib. 1. §. 1.

§. 14. The Sixth Lemma is, That if any Arc, which is Given in it's Poſition, as *AB*, be Subtended by the Chord *AB*, and in ſome Point *A*, in the Middle of it's Curvature, ſhou'd be Touch't by a Right Line *AD* Produced on both Hands, and afterwards the Points *A*, *B*, ſhou'd come together and Coaleſce, it is Affirm'd, That the Angle *BAD*, contain'd under the Chord and the Tangent, will be Diminiſh'd to Infinity and at Length Vaniſh.



For let *AB* be Produc'd to *b*, and *AD* to *d*, the Points *A*, *B*, therefore Coaleſcing, and conſequently *Bb* or *Ab* lying wholly out of the Curve, it is Manifeſt, that the Right Line *Bb* or *Ab* will either Coincide with the Tangent *Ad*, or will be Drawn betwixt the Tangent and the Curve; the Laſt is Impoſſible, becauſe it is Contrary to the Nature of the Curve, to have more than one Tangent to the ſame Point, from whence it follows, that the Firſt will obtain, that is, that *Ab* or *Bb* will Coincide with *Ad*, and that the Angle *DAB* will Vaniſh.

WHICH Demonſtration comes to this, that *AB* is FIRST ſuppos'd to be the Chord of an Arc, that is, a Right Line Subtended to it, and then by the Coalition of the Points *A* and *B* not to be a Right Line, but the Point of a Curve; Unleſs therefore the Infinite Diminution of a Right Line can be Prov'd to be the Point of a Curve, or, which is the ſame, Unleſs the Point of a Right Line can be Evidenc'd to be all one with the Point of a Curve Line, the Demonſtration is not Valid, which it is Impoſſible this Philoſophy ſhou'd do, ſince, as we have ſhewn, it is not Acquainted with what the Nature of a Curve or a Right Line is, whilſt it Conſiders Them without Diſtinction, tho' they are as Different Quantities, as a Line or a Surface, or that Compar'd with a Solid; All which it yet hopes to ſolve by Diminiſhing both to Infinity, when it Comprehends, what Infinity is, ſtill Leſs, and which by it's own Confeſſions is Various, ſo that what is Infinite in one Reſpect may be Nothing in another, which if True, tho' the Curve *AB* may be Infinitely Diminiſh'd at the ſame time that it's Subtenſe is, it is not Evident, that the Point of the Curve may not be Infinitely Greater than that of the Right Line.

Lemma 11. Schol. Lib. 1. §. 1.

SECOND, Moreover whatever has been ſaid, in Relation to Lemma 2 and 3, with the Corollaries, will in like Manner have a Place here.

THIRD, If *AB* the Chord is no Part of a Right Line, a Curve cannot be Conſider'd, as a Polygone of an Infinite Number of Sides, ſeeing it will be a Part of the Curve it ſelf, which Doctrine of Polygones this Philoſophy yet Eſpouſes; if it is the Part of a Right Line and is Inſcrib'd in the Curve the Angle *DAB* will not Vaniſh even upon an Infinite Diminution; becauſe it is only the Angle of Contact, which is Equal to Nothing, or Leſs than any Right-Lin'd Angle Given.

Elem. 3. Prop. 16. Schol. Tacquet.

FOURTH, That *Bb* or *Ab* cannot be a Tangent to a Curve, where *Ad* is made to be one, nor Comprehend an Angle with it, is Demonſtrated in *Euclid* upon the Suppoſition, that a Curve Line cannot Coincide with a Right, excepting in one Point; To prove therefore, that *Bb* or *Ab* does not make an Angle with *Ad*, becauſe *Ad* can only Touch the Curve in the Point *A*, which is ſuppos'd, is no other than to Prove by ſuppoſing; for if that is not ſuppos'd, *Ab* or *Bb* by Coinciding with the Curve may Conſtitute an Angle *bAd*, nor will it be neceſſary, that *Ab* or *Bb* ſhou'd fall without the Curve; what I mean is, that a Curve may, for all that is yet Demonſtrated in *Euclid*, or any where elſe, Coincide with a Right Line, where the Receſſion of the Tangent from the Center, and the Concavity of the Curve to it, is ſo Small, that there ſhall not be the Leaſt Difference, as in the Infinitely Large Circles of *Saturn*'s or *Jupiter*'s Orbits.

ON the Contrary, if it is not ſuppos'd, but prov'd from the Nature of a Curve and Right Line, which conſtantly Recede from each other, it cannot yet be Evinc'd, that the Points *A*, in the Tangent and the Curve, Coaleſce or are the Same; ſince, if the Nature of the Curve is Different from that of the Right Line in every Part betwixt *Ad* and *Ab*, it is neither Rational nor Juſt to think, becauſe they Touch each other in the Point *A*, that from that Contact they become of the ſame Nature; the Curvity of the one and the Rectitude of the other will ſtill in all Reaſon and Senſe be Preſerv'd; Thus, if a Line Touches a Surface or a Solid, it do's not by that Contact change either into a Surface or a Solid; which if true, tho' the Angle *dAb* ſhou'd Vaniſh, it wou'd not be any Proof, that *A*, when it Reſpects the Right Line, and when it Reſpects the Curve, wou'd be the ſame.

BUT what is farther to be taken Notice of here is, that all Matters are Clear and Indiſputable concerning the Angle of Contact, according to this Lemma; For if the Angle *BAD* upon an Infinite Diminution Vaniſhes, or is Equal to Nothing, it is Evident, that the Angle of Contact is not Leſs than any Acute one Given, becauſe the Angle of Contact cannot be Leſs than Nothing, to which an Acute Angle Infinitely Diminiſh'd is by this Lemma Equal; And yet it is known, that this has been a Controverſy betwixt the moſt Celebrated Geometers, and not as yet finally Determin'd, tho' Dr. *Wallis* has ſpent no Leſs than near 60 Pages in Folio on that Subject; *Clavius* and his Advocates Affirming on the one Hand, that the Angle of Contact is an Angle Diviſible in *Infinitum* by the Peripheries of a Circle, that it is yet Leſs than any Acute Angle Given, and that the Angle of the Semicircle is Leſs than

Dr. Wallis Oper. Math. Vol. 2. Pag. 605. ad Pag. 664. De Angulo Contactus.

than a Right Angle, but Greater than any Acute Angle Given; whereas *Peletarius* on the other Side Contends, that it is no Angle or Quantity, that the Tangent Coincides with the Curve, and that the Angle of the Semicircle is the ſame with and Equal to a Right one; And notwithſtanding all, which Dr. *Wallis* has Argued at Length upon this Occaſion, I do not ſee any better Solution of thoſe Difficulties and Paradoxes, which are Commonly Propoſed on this Head, than what is Deriv'd from the Doctrine I before Alledg'd in Relation to Curves, namely, that They are of an Heterogeneous Nature to Right Lines, and conſequently, that Rectilineal Angles and Angles of Contact or Contingence can be no more Compar'd with Each other, than Lines with Surfaces, or Surfaces with Solids. And this perhaps will give an Account of that Diſpute, which we find betwixt the Lord *Brouncker* and Dr. *Wallis* concerning the Diameters of Certain *Curves* or *Paraboloeids* in the Mathematical Works of the Latter.

Dr. Wallis Oper. Math. Vol. 1. P. 231.

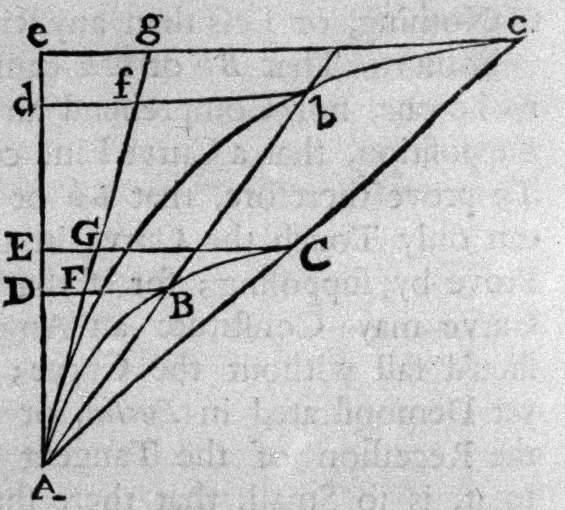
The Seventh and Eighth Lemmas Explain'd. Sir Iſ. Newt. Princip. Lem. 7, 8.

§. 15. THE Seventh Lemma is, That the ſame Things being ſuppoſed, which were in the Former Lemma, the Ultimate Reaſon of the Arc, Chord, and Tangent to one another, is the Reaſon of Equality; which, ſo Evidently depending upon the Former, there will be no Occaſion to conſider here.

THE Eighth is, That if the Right Lines Given, *AR*, *BR*, with the Arc *AB*, the Chord *AB*, and the Tangent *AD*, conſtitute Three Triangles *ARB*, *ARB*, *ARD*, and the Points, *A*, *B*, afterwards come together; the Ultimate Form of the Evaneſcent Triangles is that of their being Similar, and their Ultimate Reaſon, that of Equality; which likewiſe is Demonſtrated upon the Union of the Points, *A*, *B*, in the ſame manner, as has been already Examin'd.

The Ninth Lemma Conſider'd and Examin'd. Sir Iſ. Newt. Princip. Lem. 9. Lib. 1. §. 1.

§. 16. THE Ninth Lemma is, That if the Right Line *AE* and the Curve *AC*, Given in their Poſition, mutually Interſect each other in a Given Angle *A*, and *BD*, *EC*, which meet the Curve in *B* and *C*, are Apply'd as Ordinates to the Right Line *AE* in Another Given Angle, and the Points, *B*, *C*, ſhou'd afterwards Unite or Coaleſce in *A*; The Areas of the Triangles, *ADB*, *AEC*, will be at laſt to one another in a Duplicate Reaſon of their Sides; Which alſo is Deriv'd and Concluded from the ſame Kind of Reaſoning.



AND in all theſe Caſes it is ſuppos'd, that by an Infinite Diminution the Curve is Reſolv'd into a Right Line, and puts on the Properties of it, the Contrary of which we Affirm, and have Endeavour'd to Evince; If it be ſaid, that in Reality it is Confeſs'd, the Points of a Curve and of a Right Line are not the ſame, but yet to Appearance they may be Conſider'd as ſuch, becauſe our Senſes cannot Diſtinguiſh betwixt them; We Anſwer, FIRST, that, if theſe Principles are not Real, and are only Calculated upon falſe Appearances, it cannot well be Imagin'd, how they ſhou'd Account for Effects in Nature, which are Real and not to be Conſider'd as falſe Appearances.

SECOND, Suppoſing we ſee a Planet, as one of *Jupiter's* Satellits for Inſtance, Revolving in a Circle, and we Reduce that Curve to a Tangent and Centripetal Force, of which it ſhould prove the Curve does not Conſiſt, it will not be a juſt Explanation of the Real Revolution of that Planet, becauſe the Tangent and the Line, which Expreſſes the Centripetal Force, upon an Infinite Diminution, cannot by our Senſes be Diſtinguiſh'd from a Point in the Curve.

The Tenth Lemma Conſider'd and Examin'd. Sir Iſ. Newt. Lem. 10. Lib. 1. §. 1. Dr. Gregory's Aſtronom. Prop 23. §. 4. Lib. 1.

§. 17. THE Tenth Lemma is, That Spaces, which a Body Deſcribes by any Regular Force Urgeing it, are in the very Beginning of the Motion in a Duplicate Reaſon of the Times. Let the Times be Expreſs'd by the Lines, *AD*, *AE*, and the Velocities Produc'd by the Ordinates, *DB*, *EC*, and the Spaces Deſcrib'd by theſe Velocities will be, as the Areas, *ABD*, *ACE*, Deſcrib'd by theſe Ordinates, that is, by *Lem.* 9, in a Duplicate Reaſon of the Times, *AD*, *AE*, in the very Beginning of the Motion.

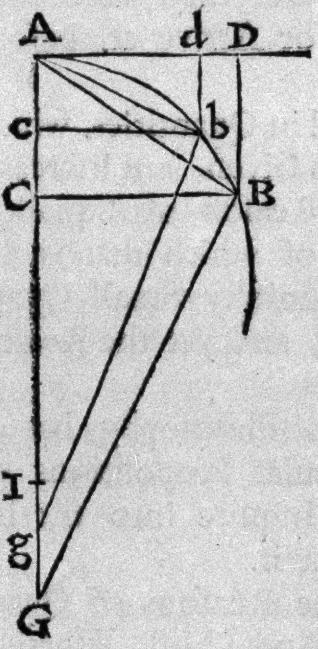
THIS Lemma, tho' it is Propos'd in the General of a Regular Force, and of that Force Acting upon or Urgeing Body Uniformly, is Primarily meant of Gravity, and that Explication, which by the Mechanick Philoſophers has been Given of it; In which Account, It is ſuppos'd, that all Matter is Similar and Alike, that it only conſiſts of Extenſion into Length, Breadth, and Depth, that it is Solid or Impenetrable, that it is Moveable and Diviſible, *&c.* all which are Properties, which make it Paſſive in it's Nature, and are Form'd in the Mind in Order to uſe it at Pleaſure; And the whole Maſs of Matter, as Philoſophy goes and is now underſtood, is nothing more than an Heap or Congeries of Abſtracted Notions Arbitrarily put together, as we have ſhewn in the Firſt Part of the *Principles* of *Natural Philoſophy*.

After this is done, it is in the next Place ſuppos'd, that Gravity or the Regular Force Acts upon this Abſtracted Matter by Continual Impulſes, ſo that in One Inſtant of Time it receives one Stroke from Gravity, in a Second Inſtant of Time Another, and in a Third, the Stroke or Impulſe from Gravity is ſtill Repeated, and ſo on; From whence the Times are Repreſented by one Side of the Triangle, which proceeds as 1, 2, 3, 4, *&c.* and the Impulſes or Strokes from Gravity, or the Velocities, which are the Effects of them, by the other, which has the ſame Arithmetical Progreſſion; and what ſeems to be Intended in this Lemma, by a Regular Force in General is only any Force, which Acts with the ſame Uniformity, be it Greater or Leſs than Gravity, with which Gravity is thought to do, that is, which Produces Effects Proportional to the Times, in which they are Produced.

Both theſe Doctrines we have therefore Conſider'd in the Firſt Part of our Said *Principles* of *Philoſophy*, namely, the Homogeneouſneſs of Matter, and the Uniform Impulſes of Gravity, and that which Remains therefore upon this Lemma, to Convince us of, is, that if we reduce, ADB, AEC, to Infinitely Small Parts towards A, they will be the ſame as Rectilineal Triangles in the Beginning of the Motion, that is, upon an Infinite Diminution of the Times and the Forces; which likewiſe has been already Conſider'd and Refuted in this *Doctrine* of *Naſcents* and *Evaneſcents*.

The Eleventh Lemma Explain'd. Sir Iſ. Newt. Princip. Lem. 11. Lib. 1. §. 1. Dr. Gregory's Aſtronom. Prop. 24. §. 4. Lib. 1.

§. 18. The Laſt Lemma is, That the Evaneſcent Subtenſe of the Angle of Contact is Ultimately in a Duplicate Reaſon of the Subtenſe of the Conterminate Arc; that is, AB Square is to Ab Square, as BD is to bd.



To which we need not Anſwer any more, than that in order to this Demonſtration, there is ſtill Requir'd a Coaleſcence of the Points, D, B, G, into thoſe of, d, b, g, and all the Conſequences of ſuch a Coalition are Affirm'd, which have been hitherto Diſprov'd.

Besides, if ſuch a Coalition is Allow'd, it is Plain, that $AB.Ab::AD.Ad$, but $AD.Ad::DBq.dbq$, becauſe AbB is a Curve Convex to AD the Abſciſs, that is, the Forces, according to §. 10, will be Greater in the Ordinates than in the Abſciſs, and therefore it will not be as $ABq.Abq::BD.bd$, but, if any Thing, on the Contrary, as $AB.Ab::BDq.bdq$.

The Scholium of the Eleventh Lemma Explain'd and Examin'd. Sir Iſ. Newt. Princip. Lem. 11. Schol. Lib. 1. §. 1.

§. 19. We ſhall therefore conclude this Inquiry into the *Doctrine* of *Evaneſcents*, with an Examination into the General Defenſe, which is made of it.

It is ſaid therefore, that theſe Lemmas are Premis'd, that the Perplexed Demonſtrations *ad Abſurdum* of the Antient Geometers might be Avoided; that by the *Method* of *Indiviſibles* they are indeed rendred more Contracted, but becauſe the *Hypotheſis* of *Indiviſibles* is Harſh and Leſs Geometrical, the Preſent *Method* of *Naſcent* and *Evaneſcent Reaſons*, which is ſaid to be Demonſtrated, is Subſtituted in it's Room; That is, the Ultimate Sums or Reaſons of the Evaneſcent Quantities, and the Firſt of the Naſcent, or the Limits of the Sums or Reaſons are conſider'd in this Method, and not the Quantities themſelves, as Diviſible to Infinity; And therefore that, when this Philoſophy ſpeaks of Quantities, as conſiſting of Particles, or makes uſe of ſmall Curve Lines for Right, it wou'd not be underſtood to mean Indiviſibles, but Evaneſcent Diviſibles, not the Sums or Reaſons of Determinate Parts, but the Limits or Determinations of thoſe Sums or Reaſons.

It yet Confeſſes, that there may be Two Objections made againſt this Method, Firſt, that of Evaneſcent Quantities there is no Ultimate Proportion, ſince, before they Vaniſh, it is not the Laſt, and after they Vaniſh, there is None.

In Anſwer to this we are told, that by the ſame Argument it may be Conteſted, whether there is any Ultimate Velocity of a Body proceeding to a Certain Fixed Point; for ſuch a Velocity, before it reaches the Point, will not be the Ultimate, and after it has reach'd it, will be no Velocity; The Anſwer to which is ſaid to be Eaſy, namely, that by the Ultimate Velocity is Meant or Intended, Neither that, with which a Body is carried, before it Arrives at the laſt Point, nor after it has Arriv'd to it, but that, which it Poſſeſſes at the very Point of it's Arrival, with which it Reaches the Laſt Point, and with which it's Motion Ceaſes; In like Manner, by the Ultimate Reaſon of Evaneſcent Quantities, is to be underſtood the Reaſon of Quantities, not before they Vaniſh nor after, but with which they Vaniſh. Thus alſo the Prime or Firſt Reaſon of Naſcent Quantities is the Reaſon with which they Riſe; and the Prime and Ultimate Sum is that, with which they Begin and Ceaſe to be, whether to be Increas'd or Diminiſh'd.

There is farther a Limit or Term, which Velocity in the End of it's Motion can Reach, but not go Beyond, this is the Ultimate Velocity; And the ſame Reaſoning obtains in Reſpect of the Limit or Term, which is Fixed to all Quantities and Proportions, that have a Beginning and an End; And ſince this Limit is Certain and Definite, it is a Problem truly and really Geometrical, to Determine it; But all Things, which are Geometrical, are juſtly allow'd and made uſe of in the Determining of what elſe is ſo.

A Second Objection, which is own'd may be made againſt this Doctrine, is, that, if the Ultimate Reaſons of the Evaneſcent Quantities are Given, there will alſo be Ultimate Magnitudes confeſs'd, and ſo every Quantity will conſiſt of *Indiviſibles* contrary to *Euclid*'s Doctrine of *Incommenſurables.*

This Objection however is ſaid to depend upon a falſe Hypotheſis, for the Ultimate Reaſons, with which Quantities Vaniſh, are not in Truth the Reaſons of Ultimate Quantities, but the Limits, to which the Reaſons of Quantities Decreaſing without End always Approach, and to which they can come nearer than according to any Given Difference, but can never go Beyond, nor Touch or Arrive at, before the Quantities are Diminiſh'd to Infinity.

This Matter, we are Inform'd, will be more clearly underſtood in Quantities, which are Infinitely Great; ſince if Two Quantities, whoſe Difference is Given, are Increas'd to Infinity, their Ultimate Reaſon will be Given, namely, a Reaſon of Equality, and yet the Ultimate or Greateſt Quantities will not be Given, of which that is the Reaſon, namely, of Equality; and the ſame may be ſaid of Infinitely Small Quantities, which are not Given, but are Diminiſh'd without Bounds, and yet the Reaſon of them may be Known and Determin'd.

An Examination into the Doctrine Aſſerted in the foregoing Scholium.

§. 20. This is a Perfect Account of the Notions, which this Philoſophy has of it's *Method* of *Naſcents* and *Evaneſcents* in General, the Particular Propoſitions of which we have before Conſider'd, and we ſhall now moreover Inquire into the Intimate Thoughts, which it has Communicated to us concerning it.

The whole of which is Reſolv'd into This; namely, Firſt, The Reaſons of Quantities; Second, The Quantities of which they are the Reaſons; And Third, Whether we can conſider the One without the Other; Theſe are the Three Things to be Examin'd into, in the Preſent Doctrine.

Before I do which, I muſt obſerve, that the *Doctrine* of *Indiviſibles* is own'd to be of the ſame Kind, as it Really is, with that of theſe *Naſcents* and *Evaneſcents*, the Former yet is Diſcarded, as being Contrary to *Euclid*'s *Doctrine* of *Incommenſurables*, and for the ſame Reaſon ought this to be, which is as Directly Oppoſite and Repugnant to it, in which Curves and Right Lines of the moſt Different Nature and Conſtitution are ſuppos'd to Coincide in a Point, and therefore to obtain one Common Meaſure; To omit this notwithſtanding,

First, This Philoſophy ſays, it only Conſiders the Reaſons of Quantities, and not the Quantities themſelves; whereas, in the Anſwer to the Firſt Objection, it ſuppoſes, that there is an End of the Velocity, which is made uſe of as a Parallel Inſtance to Quantity, and therefore, that there as an End of the Quantity it ſelf, whoſe Evaneſcent Reaſon is Conſider'd, and in the Second Objection from Incommenſurables and Quantities Infinitely Great, that there is no End of the Quantity, whoſe Reaſon is Conſider'd, which is a Contradiction.

SECOND, It is in the Next Place to be Obſerv'd, that even in the Reaſons of Quantities, if thoſe only were to be Regarded, it does not make any Juſt Concluſions, according to it's own Sentiments; for albeit Quantities are never ſo Different, if they are but ſuppos'd Infinitely Increas'd or Diminiſh'd, their Reaſon will be that of Equality according to this Philoſophy, notwithſtanding, that all the Naſcent and Evaneſcent Reaſons of Different Quantities are Imagin'd to be Different, which is again a Contradiction.

BUT if Quantities only, which are Equal, upon the Infinite Increaſe or Diminution of them, have their Reaſons of Equality, there is no great Myſtery in the Matter, becauſe, if Quantities are Equal, their Reaſons or Proportions will be ſo too.

THIRD, After what we have ſaid in Confutation of the Preſent Doctrine of Naſcents and Evaneſcents from it ſelf, we ſhall only Affirm, that Quantities and the Reaſons of Quantities are the ſame, and that we cannot conſider the One without the Other; that is, the Reaſons of Things are their Quantities, and *Vice Verſâ*, Quantities are nothing elſe but the Reaſons of Things.

FOR what are Quantities themſelves, unleſs the Reaſons or Relations of Things, when compar'd with one another? Thus a Right Line, or a Curve, or a Rectilineal, or Curve Figure, as a Square and a Circle, are Quantities only, as they are capable of Relation; for if they are barely Conſider'd, as one Uniform and Abſtracted Extenſion without any Properties of what they are in Reſpect to other Lengths or Figures, either contain'd in themſelves, as Portions of them, or Diſtinct from them, they cannot be in any Senſe Term'd Quantities; when therefore we Inquire into the Ultimate Reaſons of Reaſons', if that is a Proper Way of Speaking, which yet is the Real Meaning of this Philoſophy, we muſt know what thoſe Reaſons are, whoſe Ultimate Reaſons we wou'd Determine, or elſe it will be Impoſſible for us to Demonſtrate with any Degree of being Intelligible; that is, it will be neceſſary for us to Inform our Selves of the Nature of thoſe Lines or Figures, whoſe Ultimate Reaſons are Inveſtigated, before we can Fix or Aſcertain ſuch Ultimate Reaſons.

FOURTH, Moreover, according to the Doctrine of Velocities in the *Geometry* of *Solids*, one and the ſame Line to Appearance may be capable of a Thouſand Different Values, if the Velocities, by which it is Produc'd, are Various; whereas the Preſent *Method* of *Naſcents* and *Evaneſcents* does only ſuppoſe the ſame Abſtracted Length, as it Lies in the Figure, without Conſidering, with what Velocity it is cauſ'd or receives it's Dimenſion.

Geometria Solidorum ſive Materiæ.

FIFTH, Laſtly as Length or Breadth is Accounted one Similar and Invariable Extenſion in this *Method*, ſo is Infinity Equally Determin'd to be one Uniform Exhauſtion of Quantity; whereas, if Quantities are Different, one Uniform Infinity cannot Equally Exhauſt both, for Inſtance, if One Line in Reſpect of Another, as in the *Geometry* of *Solids*, may have the ſame Relation, as that of a Line and a Surface or a Solid, one Uniform Infinity can no more Exhauſt the Points of Each of them, than by Infinitely Diminiſhing a Line we can Exhauſt a Surface or a Solid; and the ſame may be ſaid of Two Different Lengths, for Example, let One be the Double of the Other, if Infinity is one Uniform Thing, they cannot be Equally Exhauſted by it, but when one is Exhauſted, there will be only Half of the other Deſtroy'd.

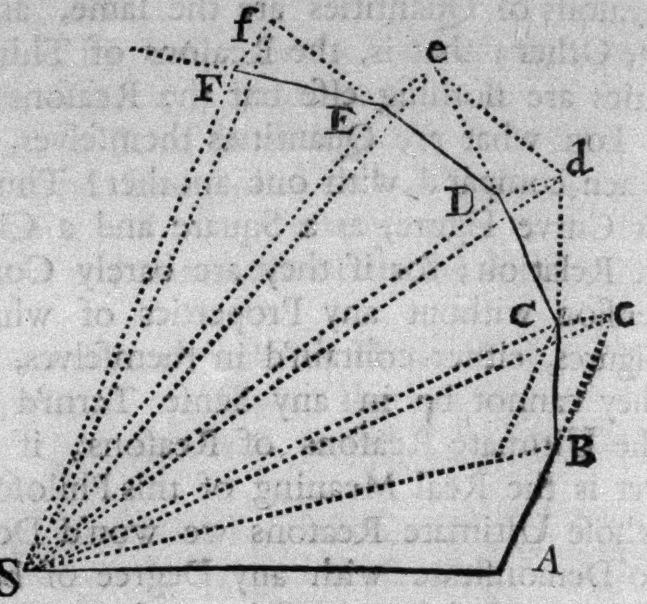
IF Infinity is not one Uniform Idea, but puts on Different Qualities and Shapes, it is in Short no more than this, that is, an Univerſal Deſtroyer of Unequal Quantities, which the Mind Employs to Devour and Annihilate all the Excreſcencies or Exorbitancies of them, which it has no Occaſion for in it's Abſtracted Reaſonings, and which, if not taken out of the Way, wou'd be Troubleſome to it; and ſomething like this is the Caſe of Infinity, when Apply'd to Quantities Infinitely Increas'd, which let them be what they will, and how Different ſoever Originally, ſhall from thence, it ſeems, become Equal; Infinity Deſtroys the Difference, and makes them all one, which is Impoſſible; for an Infinite Number of Inches cannot be the ſame, as an Infinite Number of Yards, or Miles, or Semidiameters of the *Moon*, of the *Earth*, or of the Orbits of *Jupiter* or *Saturn*; unleſs Infinity is ſomething not certain, excepting that it obtains one Quality, which is, of making all Things Equal, which, when Finite, were not ſo.

CHAP. IV.

Concerning the Fundamental Propoſitions of this Philoſophy, and the Application of them to the Solving the Revolutions of the Planets.

The Firſt Propoſition Conſider'd and Examin'd.
Sir Iſ. Newt. Princip. § 2. Prop. 1. Lib. 1.
Dr. Gregory's Aſtronom. Prop. 11. §. 2. Lib. 1.

§. 1. HAVING in the Former Chapter Conſider'd the *Doctrine* of *Naſcents* and *Evanaſcents*, we are now come to the Propoſitions and Theorems of this Philoſophy; The Firſt of which is, That if a Body is Mov'd according to the Direction from *A* to *B*, and at the ſame Time is Urg'd by a Centripetal Force from *A* to *S*, a Curve Line will be Deſcrib'd, and whilſt the Body Deſcribes that Curve Line, the Areas will be Proportional to the Times of the Body's Revolving in ſuch a Curve; or, which is the ſame, as it is Expreſs'd in this Philoſophy, The Areas, which Bodies Deſcribe, when carry'd about by Radius's drawn to an Immoveable Center of their Forces, are in Immoveable Planes, and are Proportional to the Times of their Revolving.



THUS, Let the Time be Divided into Equal Parts, and in the Firſt Portion of it, Let the Body Deſcribe by it's Innate Force the Right Line *AB*, the ſame Body, if nothing were to Hinder or Obſtruct it, wou'd proceed to *c*, and by Law the Firſt Deſcribe *Bc* = to *AB*, ſo that by Drawing the Lines, *AS*, *BS*, *cS* to the Center *S*, there wou'd be Equal Areas perform'd *ASB*, *BSc*, but when the Body comes to *B*, Let the Centripetal Force be ſuppos'd to Urge it by one Impulſe, and by that means make it Decline from *Bc*, and proceed forwards in the Line *BC*; Let *Cc* be drawn Parallel to *BS*, and meet the Line *BC* in *C*, If this is ſuppos'd, upon the Completion of the Second Portion of Time, by *Corol.* 1. of the Laws, the Body will be found in *C*, in the ſame Plane with the Triangle *ASB*; Join *S*, *C*, and the Triangle *SBC* will be Equal to the Triangle *SBc* = Triangle *SAB*, becauſe *SBC*, *SBc*, have the ſame Baſe *SB*, and lie within the ſame Parallels, *SB*, *Cc*; By a like Method of Arguing *SCd*, *SCD* will be Prov'd Equal, and ſo on; From whence it will follow, that, in Equal Times, Equal Areas are Deſcrib'd in a Plane, which is Unmov'd, and by Compounding any Sums of theſe Areas, *SADS*, *SAFS*, are to One Another, as the Times of their Deſcription.

LET now the Number of the Triangles be Increas'd, and the Latitude of them Diminiſh'd to Infinity, and their Ultimate Perimeter *ADF*, by the 4th *Coroll.* to *Lem.* 3. will be a Curve Line; and therefore the Centripetal Force, by which a Body is perpetually Drawn out of the Tangent of this Curve, will Act Continually and Inceſſantly upon it; And any Areas, *SADS*, *SAFS*, Deſcrib'd Proportional to the Times of Deſcription will be, in this Caſe, Proportional to the ſaid Times, *Q. E. D.*

IN which Demonſtration we ſhall Conſider; First, The Generation of this Figure upon the Suppoſition of the Preſent Abſtracted Forces; Second, What Alteration Different Magnitudes in the Bodies, which are Mov'd, wou'd Cauſe; Third, What wou'd be the Conſequence, if other Forces were Introduc'd, whether Projectile or Attractive in a Different Proportion to each other, from what is here Preſum'd; Fourth, What wou'd follow, if Forces perfectly Diſtinct from either of theſe ſhou'd be made uſe of.

The Forces by which this Figure is Generated, and the Way of Gene-

§. 2. FIRST, It is ſuppos'd, that *A*, by it's Innate Force, proceeds from *A* to *B* in one Portion of Time, and in an Equal Portion of it Deſcribes *Bc* Equal to *AB*, that is, a Perfect Inertia of Matter is Preſum'd, and that upon it's Motion it will have a Conſtant and Uniform Progreſs, unleſs it is Interrupted by ſome External

Agent, but to conſider Matter, as an Unactive Maſs, and only Capable in it ſelf of Receiving that Impulſe, which we Give it, is Firſt Making it a Creature of the Mind, and then Uſing it at our own Pleaſure; For this we have Prov'd to be the Senſe of a Similar, Paſſive, or Homogeneous Matter, And what we Mean and Intend in theſe Principles is only, with all Submiſſion, to Take it out of the Hands of the Philoſophers, and Reſign it to it's own Nature and the Great Author of it.

ration by Them liable to many Objections; And Firſt of the Projectile Force.

Let us yet ſuppoſe, that Matter or Body is Similar, Paſſive, or Homogeneous, and that it has no Action of it's own; we Ask, Does Almighty God Impart that Action to it, by which it proceeds Uniformly from *A* to *B*, or is it done by the Mind of the Philoſopher? If the Firſt, How is it known in what Proportion an Infinite Being Acts upon it? Why may not the Impreſſion, ſuitable to the Energy of the Almighty Agent, be ſo Forcible and Strong, that no Centripetal Action whatſoever ſhall be able to divert it's Progreſs? The Caſe is too Evident and Plain, that, if this Projectile Force was Deriv'd from God, Matter wou'd be as little in the Power of the Philoſophers to Manage and Direct it, as they pleas'd, as if they had never ſuppos'd it Paſſive; and therefore ſuch a Conceſſion wou'd deſtroy the very Intention of making Matter Paſſive and Homogeneous, namely, that of Contriving it into what Shapes, Figures, or Motions, ſhould be thought Fit or Convenient for a Preſent Solution.

If therefore the Progreſs of Matter or Body from *A* to *B* is under the Will and Direction of the Philoſopher, Let us now Inquire which way that Motion is Produced, when Matter is ſuppos'd to be perfectly Unactive in it ſelf; the Mind cannot by Thinking put it into Motion, nor can our own Imaginations, be they as Vigorous as they will, Actuate a Dead Lump, and Throw it into an Uniform Projection; Since then the Preſent Scheme does not Inform us, how in Unactive Matter a Projectile Force from *A* to *B* is Impreſs'd upon it, tho' all, which is here propoſed to be Demonſtrated, were true upon the Suppoſition of ſuch a Projectile Force, yet, when apply'd to Nature, the Body wou'd be Quieſcent in *A*, and there wou'd not be the Leaſt Advance made from *A* to *B*, and conſequently, the Revolution of the Planets cou'd not be Explain'd by ſuch a Scheme; If it is again ſaid, that Almighty God Impreſſes this Force upon Bodies, which, being Paſſive of themſelves, wou'd continue that Force *in Directum*, if not Interrupted by Gravity, which is ſuppos'd to be Deriv'd from him likewiſe, we ſhall ſeem, I'm afraid, to make the Sovereign Diſpoſer of the Univerſe a Capricious Kind of Agent, whilſt he Puſhes the Unactive Maſs One Way and Draws it Another, and Created it Unactive too, that he might be Employ'd in ſuch a Ludicrous Paſtime; It is told us, that Nature always takes the ſhorteſt Methods to Effect it's own Purpoſes, and it is a Fundamental Maxim of the Preſent Philoſophy; but ſurely then the wiſe Former and Maker of Nature it ſelf wou'd not Create a Maſs without Action, in order afterwards to Impreſs Two Different ones upon it, which might be Effected by one; Indeed this Notion has too great a Reſemblance of the Fancies and Artifices of Philoſophers to be Entitled to the being a Divine, which is plainly no more, as we ſhall ſhow, than a Human Contrivance.

After having ſaid what foregoes, we ſhall now Proceed to Inquire into the Generation of this Figure, ſuppoſing *A* to be a Body conſiſting of Homogeneous Matter, and that there is a Projectile Motion given to it, which carries it Uniformly from *A* to *B*, and from thence to *c*, and ſo on; Either then the Projectile Motion AB is Equal to $Bc = Cd = De = Ef$, or not, If Equal, when the Body Departs from *C* to *d*, it will have the ſame Projectile Force, as when it Proceeds from *B* to *c*, or from *A* to *B*, Notwithſtanding, that it is continually Urg'd by a Contrary Force, which Preſſes it towards *S*, which is Abſurd and Irrational; unleſs a Projectile Motion can riſe out of it's Oppreſſion from Gravity with as much Vigour at *C*, as before that Load was thrown upon it at *A* or *B*, which will ſhow a Vivacity in Matter ſomething Superior to that Tameneſs and Paſſiveneſs, which this Philoſophy preſcribes to it; Becauſe, if a Force was to Act Contrary to the Projectile, that is, from *B* to *A*, from *c* to *B*, or from *d* to *C*, the Projectile from *A* to *B*, from *B* to *c*, or from *C* to *d* wou'd be evidently Diminiſh'd, and if Equal to it, wou'd be Deſtroy'd, how therefore a Force Acting towards *S*, which is in ſome Meaſure Contrary to it, ſhou'd not in the leaſt Diminiſh the ſame Projectile Force, is Impoſſible to ſay.

If AB, Bc, Cd, De, Ef, are not Equal; In the Firſt Place, that will be Deny'd, which is here Affirm'd and Suppoſ'd, *viz.* that AB, Bc, Cd, &c. are Equal. Second, There is no more Reaſon to Suppoſe or Affirm, that Bc is Equal to AB, than that Cd is, for when the Body Moves from the Point A to B, ſuch a Projectile Force is not Clearer from an Attractive one, than Bc is; and therefore, if Cd is not Equal to Bc, for the ſame Reaſon Bc will not be Equal to AB, which is yet ſuppos'd, and the ſame may be ſaid of the Reſt. Third, If the Projectile Motion AB is not Equal to Bc Equal to Cd, what is it Equal to? If AB is Equal to Bc, and BC to Cd, CD to De, &c. which is the only Caſe Remaining, it will be Inconceivable, how the Motion of the Body in AB, BC, CD, DE, &c. which is Compounded of a Projectile and Gravitating Force, ſhould be Equal to the Motion of it in Bc, Cd, De, &c. where the Force is only ſuppos'd to be a Projectile one, Abſtracted from a Gravitating. Fourth, If BC, Cd, &c. are not Equal, the Reaſon of it will be, that BC is a Compound Force, and Cd only a Projectile, But how a Projectile ſhould riſe out of a Compound without being Affected with the Gravity, which was Impreſs'd from B to C, that is, how there ſhou'd ever be a ſingle Projectile Force after ſuch a Compound, is altogether Inexplicable.

Concerning the Attractive Force in this Figure, and what Relates to it.

§. 3. Having conſider'd the Projectile Force in the Preſent Scheme, let us now Examine into the Attractive, which may be Expreſs'd by cC, dD, eE, fF, ſince the Effect is neither Greater nor Leſs than the Cauſes, which produce it; The Effect is the Body's Revolving in the Diagonal Lines BC, CD, DE, whoſe Projectile Force is Bc, Cd, De, and conſequently, the Gravitating may be Deſcrib'd or Repreſented by Cc, Dd, Ee, according to this Philoſophy.

Either therefore theſe Attractive Forces, as the Projectile before, are Equal, or not; If they are Equal, ſince Bc or elſe BC muſt be Equal to Cd by what Precedes, and ſince the Attractive Quality cannot draw the Body down from one Projectile Force more than another, that is, ſince the Angles cBC, dCD will be Equal, it will follow, that thoſe Triangles are likewiſe Equal, and that therefore Bc is Equal to Cd, and BC to CD, or that BC is Equal to Cd, and Bc to CD, both which have been already Diſprov'd.

Moreover, if AB is the Projectile, where is the Gravitating Force, which belongs to it, that is Equal to Cc the Gravitating Force of the Projectile Bc? and why does not the Figure begin at B rather than at A, Unleſs it were for a private Reaſon, becauſe BC does not look ſo much like a Projectile, which is Compounded of that and Gravity, as AB does?

If Cc is not Equal to Dd, Equal to Ee, that is, if there is not the ſame Attractive Force, which Perverts the Body from the Tangent or Projectile, Matter, which is own'd to be perfectly Paſſive, will Aſſume of it ſelf Different Powers of Gravitation, and therefore are ſuch, as cannot be Deriv'd from any other Cauſe than that of the Pleaſure of the Philoſopher.

It may be farther ſaid, that the Propoſition, upon which the Preſent depends, namely, that the Force of the Diagonal may be Reſolv'd into the Sides of the Parallelogram, has been already Prov'd to be falſe in our Conſideration of the Laws of this Philoſophy, and the Corollaries of them, and therefore Bc and cC are not in Truth Expreſſive of the Force in BC, tho' we have hitherto Acknowledg'd it, and Argued againſt the Preſent Theorem upon that Suppoſition.

Lastly, We have ſhewn in the Examination into the Doctrine of Naſcent and Evaneſcent Reaſons, that if the Right Lines Bc, Cd, cC, dD, were Diminiſh'd to Infinity, it is not neceſſary they ſhou'd form a Curve, which this Propoſition Affirms; Since the Nature of One or Two Right Lines, as Bc and cC, tho' Join'd and United together, may be Infinitely Different from the Nature of a Curve, which cannot, in ſome Caſes, be Meaſur'd by any Right Lines, or any Conjunction of them whatſoever; It is alſo ſomething Extraordinary to make, in this Demonſtration, the Centripetal Forces not Tend to the Center, but Act in Lines Parallel to thoſe, which are Directed thither; But This we Omit.

Concerning the Magnitude of the Body, the Revolution of which is Inquir'd.

§. 4. Second, The next Thing to be conſider'd is the Magnitude of the Body, the Revolution of which is Inquir'd, if Matter or Body in General is nothing elſe than an Abſtracted Idea, it has no Qualities beſides thoſe, which the Mind of the Philoſopher gives it, which may Band about it's own Creature, as it pleaſes, and let the Bulk of ſuch Matter be Greater or Leſs, it will be the ſame; For if Matter conſiſts of Extenſion in General, Solidity in General, and the like Abſtracted Properties, a Greater or Leſs Magnitude of them will be Equally Obedient to any Impulſes, which ſhall be thought convenient to Impart to it, but then all this will only Reſt in the Fancy, and there Determine.

ON the other Hand, if Matter has any Real Properties and Affections belonging to it, as particularly that of Gravity, Impreſs'd upon it from an Elaſtick Medium, or Innate, which this Philoſophy owns, This Scheme, which lies before us, will be Incapable of Affording us the Leaſt Satisfaction or Demonſtration Concerning the Revolutions of the Heavenly Bodies, for which it is Deſign'd; Since, if *A* is Endued with an Actual Gravity, and ſuch Gravity is Proportional to the Quantity of Matter, which is contain'd in any Body, according to this Philoſophy, if the ſame Projectile Force *AB*, or *Bc*, &c. is Communicated to Different Portions or Bulks of Matter, it will have very Different Effects from what are Expreſs'd in this Figure, which ſuppoſes that Force to be Uniformly the ſame; Effects ſo Different, that if the Force of Gravity is Infinitely Increas'd by the Immenſe Magnitude of the Body, the Projectile may be Nothing in the Compariſon, by which the Body, inſtead of being Revolv'd, will Drop to the Center, and if the Force of Gravity is Infinitely Diminiſh'd by the Extreme Smallneſs of the Body, the Projectile may be Infinite in the Compariſon, and Carry it forward *in Directum* without any Revolution.

IF it is ſaid, that according to the Greater Quantity of Matter or the Leſs, the Projectile Force Imparted to it will be Greater or Leſs, but yet Uniform, ſo as to keep up the Body from Sinking to the Center, or going Forward *in Directum*; Who is the kind Perſon, that Moderates and Tempers this Projectile Force with ſo much Beneficence and Goodneſs, but the Same, Who had the Skill to Contrive and Invent it? I mean the Ingenious Author of this Philoſophy Sir *Iſ. Newton*, Who, by the ſame Method, may at his Pleaſure Communicate what Impreſſions he will to Matter, and no one ſhall Preſume to Contradict the Humour.

FOR the Expreſſions of Gravity *cC*, *dD*, *eE*, &c. will be Various, if the Bulk or Magnitude of the Body is ſo, and therefore cannot be Explain'd by a Uniform Gravity Repreſented by thoſe Lines, but whilſt the Projectile is *Bc*, the Gravity may be Ten, a Hundred, or a Thouſand Times Greater or Leſs than *Cc*, which, if Produc'd or Leſſen'd in that Proportion, wou'd cauſe an Unſpeakable Confuſion in the Preſent Figure, and wou'd in no manner be Capable of being Exacted to it; Unleſs it is ſaid, that the Accelerating Force to the Center continues the ſame, however Different the Magnitudes are, which are Accelerated, and therefore *Cc* will Expreſs ſuch Attractive or Accelerating Force without any Alteration; To which it may be Reply'd, that this would not be True, if it cou'd be even Prov'd, that Matter is Similar and Homogeneous, or that all Bodies Deſcend Equally, and in Equal Times, to their Center of Attraction, both which Notions we have yet Endeavour'd to Confute in the Firſt Part of the *Principles* of *Philoſophy*, which we have ſome Years ago Publiſh'd, and can be only True, if we conſider Matter as a mere Abſtracted Thing, which is the ſame, whether we take a Greater or Leſs Portion of it, and which is likewiſe a Perfect Fancy and Imagination.

What wou'd be the Conſequence, if other Forces were Introduc'd, whether Projectile or Attractive, in a Different Proportion to each other from what is here Preſum'd.

§. 5. THIRD, The Third Thing propos'd was to Examine, what wou'd be the Conſequence, if other Forces were Introduc'd, whether Projectile or Attractive, in a Different Proportion to Each other from what is here Preſum'd, for, in the Preſent Caſe, at the ſame Time that the Projectile Force wou'd carry the Body Revolv'd from *B* to *c*, the Attractive wou'd Draw it from *c* to *C*; If therefore the Projectile Force ſhou'd now be Infinitely Increas'd or Diminiſh'd, whilſt the Attractive Draws it from *c* to *C*, namely upon the Suppoſition of the Accelerating Force being the ſame, the Attractive Force wou'd be carry'd away *in Directum* by the Projectile in the Firſt Caſe, and in the Laſt Ruſh to the Center; or if the Projectile were to continue the ſame, and the Attractive Force was Infinitely Diminiſh'd or Increas'd in a Body of the ſame Magnitude, the like Effects wou'd Follow, and Nothing of this Figure wou'd Enſue; from whence it is plain in all Reſpects, that this is Nothing more than an Abſtracted and Mathematick Reaſoning, which conſiders an Uniform Projectile and Attractive Force without Determining what it is, which yet is Neceſſary in a true Reaſoning.

§. 6. FOURTH,

What the Conſequence, if Forces perfectly Diſtinct from either ſhou'd be Introduc'd.

§. 6. Fourth, And laſtly, if Forces perfectly Diſtinct from Either of theſe, as thoſe in Fire, Vegetation, *&c.* or the Expanſive in General, are Introduced into the Figure, it is Manifeſt, that the Projectile and Attractive will be ſo much Alter'd, that the Preſent Figure will be entirely Annihilated and Confounded.

The Second Propoſition Explain'd. Sir Iſ. Newt. Princ. Prop. 2. §. 2. Lib. 1. Dr. Gregory's Aſtronom. Prop. 12. §. 2. Lib. 1.

§. 7. The Second Propoſition is, That every Body, which, when it is Mov'd in any Curve Line, and by a Radius Drawn either to an Immoveable Point, or to a Point that proceeds Uniformly in a Rectilineal Motion, Deſcribes Areas about that Point, which are Proportional to the Times, is Urg'd by a Centripetal Force Tending to the ſame Point.

The Demonſtration of this Propoſition ſo evidently depends upon the Former, and the Firſt and Second Laws, which have been already Conſider'd, that there is no Occaſion particularly to Examine into it.

The Third Propoſition Explain'd. Sir Iſ. Newt. Prop. 3. §. 2. Lib. 1. & Schol.

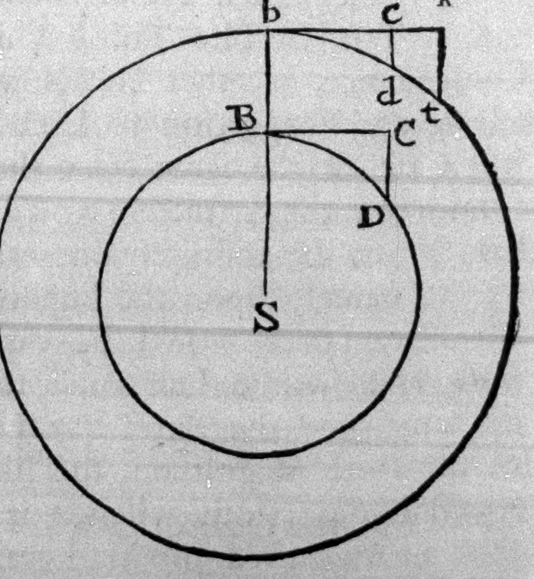
§. 8. The Third Propoſition is, That Every Body, which, by a Radius Drawn to the Center of Another Body, however Mov'd, Deſcribes Areas about that Center Proportional to the Times, is Urg'd by a Force Compounded of a Centripetal Tending to the other Body, and of the whole Accelerating one, by which the other Body is Urg'd.

The Demonſtration likewiſe of this Propoſition is concluded from the 6th Corollary of the Laws, which have been Examin'd, from the Firſt of thoſe Laws, and from the foregoing Propoſition the Second; and therefore it will not be here alſo neceſſary to make any particular Inquiry into the Preſent Reaſoning.

We ſhall notwithſtanding obſerve, that when the Firſt Propoſition had Inform'd us, that the Areas, which Bodies Deſcribe by Radius's Drawn to an Immoveable Center of their Forces, were Proportional to their Times, and on the Contrary, the Second had told us, that Bodies, which were ſo Circulated, were Urg'd by a Centripetal Force, both which Propoſitions Reſpect Curves in General, whoſe Radius's are not Determin'd whether Equal or not, we are yet in the Scholium of this Propoſition Perſuaded to Believe, that an Equable or Uniform Deſcription of Areas is an Index or Characteriſtick of a Center, whoſe Curve is Circular, and whoſe Radius's are Equal; whereas, if it were ſo, the Firſt Propoſition wou'd not be ſo General, as it is Exhibited to us, and if it is ſo General as it is Repreſented, an Equable Deſcription of the Areas can be no more Concluſive of a Circular than of any other Curve *in Spatiis Liberis*, ſince the Spaces are ſuppos'd to be ſo, in the Firſt Propoſition and the Demonſtration of it; that is, we cannot be willing to allow any more in a Philoſophy, which pretends to Mathematick Demonſtration, than what is Juſtly and Strictly concluded from ſuch Demonſtration.

The Fourth Propoſition with it's Corollaries and Scholium Explain'd. Sir Iſ. Newt. Prop. 4. §. 2. Lib. 1. Edit. 1. Dr. Gregory's Aſtronom. Prop. 25. §. 4. Lib. 1.

§. 9. The Fourth Propoſition is, That of Bodies, which Deſcribe Different Circles by an Equable Motion, the Centripetal Forces Tend to the Centers of the ſame Circles, and are to Each other, as the Squares of the Arcs, which are Deſcrib'd in the ſame Portion of Time, Divided by the Radius's of the Circles.



Let the Bodies, B, b, by Revolving in the Circumferences of the Circles, BD, bd, Deſcribe at once the Arcs BD, bd, ſince therefore by their ſole Innate or Projectile Force the Bodies, B, b, wou'd Deſcribe the Tangents BC, bc, it is Evident, that the Centripetal Forces are thoſe, which perpetually Draw the Bodies from the Tangents to the Circumferences of the Circles, and conſequently are to One Another in the Firſt Reaſon of the Naſcents, CD, cd, and Tend to the Centers of the Circles, by Prop. 2; becauſe the Areas Deſcrib'd by the Radius's are ſuppoſed Proportional to the Times; Let the Figure tkb be made Similar to the Figure DCB, and by *Lem.* 5, the Line CD will be to the Line kt, as the Arc BD to the Arc bt, And by *Lem.* 11. the Naſcent Line tk will be to the Naſcent Line dc, as bt *Square*, to bd *Square*, and *ex Æquo* the Naſcent Line

DC will be to the Naſcent Line dc, as $BD \times bt$ to bd *Square*, or, which is the ſame, as $\frac{BD \times bt}{Sb}$ to $\frac{bd \text{ Square}}{Sb}$, and therefore (upon the Account of the Equal Reaſons $\frac{bt}{Sb}$ and $\frac{BD}{SB}$) as $\frac{BD \text{ Square}}{SB}$ to $\frac{bd \text{ Square}}{Sb}$. *Q. E. D.*

FROM this Propoſition and the Demonſtration of it, It is Infer'd.

Corol. 1. THAT the Centripetal Forces are as the Squares of the Velocities Divided by the Radius's of the Circles; For DC is to dc, as $\frac{BD \text{ Square}}{SB}$ is to $\frac{bd \text{ Square}}{Sb}$ by the Propoſition, and BD and bd Repreſent the Velocities in Each, that is, the Arcs are as the Velocities. Or the Forces are in a Reaſon Compounded of a Duplicate Reaſon of the Velocities Directly, and of a Simple Reaſon of the Radius's Inverſely.

Corol. 2. That the Centripetal Forces are Reciprocally, as the Squares of the Periodical Times Divided by the Radius's; That is, theſe Forces are in a Reaſon Compounded of the Duplicate Reaſon of the Velocities Directly, and of a Simple Reaſon of the Radius's Inverſely; as alſo in a Reaſon Compounded of the Simple Reaſon of the Radius's Directly, and of a Duplicate Reaſon of the Periodical Times Inverſely. Which is eaſily ſhewn by the Arcs, BD, bd, Repreſenting their Circles.

Dr. Gregory's Aſtronom. Prop. 26. § 4. Lib. 1.

FOR ſuppoſing, V Expreſſes the Velocities, T the Periodical Times, q the Squares of Each, and c the Cubes; Since the Periodical Times are in a Reaſon Compounded of the Reaſon of the Radius's Directly, and of a Reaſon of the Velocities Inverſely, that is, ſince $BD,T . bd,T :: \frac{SB}{BD,V} . \frac{Sb}{bd,V}$, it will be, $BDq,T . bdq,T :: \frac{SBq}{BDq,V} . \frac{Sbq}{bdq,V}$, and $\frac{BDq,T}{SB} . \frac{bdq,T}{Sb} :: \frac{SB}{BDq,V} . \frac{Sb}{bdq,V}$, or $\frac{Sb}{bdq,T} . \frac{SB}{BDq,T} :: \frac{bdq,V}{Sb} . \frac{BDq,V}{SB}$; from whence it will follow by Inverſion, that $\frac{BDq,V}{SB} . \frac{bdq,V}{Sb} :: \frac{SB}{BDq,T} . \frac{Sb}{bdq,T}$, but by *Corol.* 1. $DC . dc :: \frac{BDq,V}{SB} . \frac{bdq,V}{Sb}$, and therefore $:: \frac{SB}{BDq,T} . \frac{Sb}{bdq,T}$, or $:: \frac{bdq,T}{Sb} . \frac{BDq,T}{SB}$.

Corol. 3. FROM whence it Enſues, if the Periodick Times are Equal, that both the Centripetal Forces, and the Velocities, will be as the Radius's, and *Vice Verſâ*; For $DC . dc :: \frac{SB}{BDq,T} . \frac{Sb}{bdq,T}$, or $:: SB . Sb$, if BDq,T is $= bdq,T$; Likewiſe $\frac{BDq,V}{SB} . \frac{bdq,V}{Sb} :: \frac{SB}{BDq,T} . \frac{Sb}{bdq,T}$, or $:: SB . Sb$, if BDq,T is $= bdq,T$; and therefore $BDq,V . bdq,V :: SBq . Sbq$, or $BD,V . bd,V :: SB . Sb$.

Corol. 4. IF the Squares of the Periodick Times are as the Radius's, the Centripetal Forces will be Equal, and the Velocities in a Dimidiate Reaſon of the Radius's, and *Vice Verſâ*; For ſince $DC . dc :: \frac{SB}{BDq,T} . \frac{Sb}{bdq,T}$, if DC is $= dc$, $\frac{SB}{BDq,T} = \frac{Sb}{bdq,T}$, that is, $SB . BDq,T :: Sb . bdq,T$, and by Alternation, $BDq,T . bdq,T :: SB . Sb$; Or, on the Contrary, if this Proportion obtains, DC is $= dc$; Or, if $BD,T . bd,T :: SB|^{\frac{1}{2}} . Sb|^{\frac{1}{2}}$. For This Reſults from the Former.

Sir Iſ. Newt. Princip. Edit. 2.

THE Velocities alſo will be in a Dimidiate Proportion of the Radius's, ſince $\frac{BDq,V}{SB} . \frac{bdq,V}{Sb} :: \frac{SB}{BDq,T} . \frac{Sb}{bdq,T}$ by *Corol.* 2, if therefore $SB . Sb :: BDq,T . bdq,T$, it will be as $\frac{BDq,V}{SB} . \frac{bdq,V}{Sb} :: \frac{SB}{SB} . \frac{Sb}{Sb}$, which is Evident from Proportionals being ſubſtituted in Diviſion inſtead of Proportionals, by which Means the Reaſons of the Quantities will be ſtill Preſerv'd the ſame; But, if $\frac{BDq,V}{SB} . \frac{bdq,V}{Sb} :: \frac{SB}{SB} . \frac{Sb}{Sb}$, it will be as $BDq,V . bdq,V :: SB . Sb$; And $BD,V . bd,V :: SB|^{\frac{1}{2}} . Sb|^{\frac{1}{2}}$, or $\sqrt{SB} . \sqrt{Sb}$.

Sir Iſ. Newt. Princip. Edit. 2.

Corol. 5. If the Squares of the Periodical Times are as the Squares of the Radius's, The Centripetal Forces are Reciprocally as the Radius's, and the Velocities Equal, and *Vice Verſâ.*

The First is thus Evinced, for $DC \,.\, dc :: \frac{SB}{BDq,T} \,.\, \frac{Sb}{bdq,T}$ by *Corol.* 2, Therefore $DC \times SB \,.\, dc \times Sb :: \frac{SBq}{BDq,T} \,.\, \frac{Sbq}{bdq,T}$; If Conſequently $\frac{SBq}{BDq,T}$ is $= \frac{Sbq}{bdq,T}$, that is, if $SBq \,.\, BDq,T :: Sbq \,.\, bdq,T$, or Alternately, if $BDq,T \,.\, bdq,T :: SBq \,.\, Sbq$, $DC \times SB$ will be Equal to $dc \times Sb$, or, which is the ſame, $DC \,.\, dc :: Sb \,.\, SB :: \frac{1}{SB} \,.\, \frac{1}{Sb}$. The ſame will obtain, if $BD,T \,.\, bd,T :: SB \,.\, Sb$.

Sir Iſ. Newt. Princip. Edit. 2.

Second, That the Velocities in ſuch a Caſe will be alſo Equal is Manifeſt, ſince $\frac{BDq,V}{SB} \,.\, \frac{bdq,V}{Sb} :: \frac{SB}{BDq,T} \,.\, \frac{Sb}{bdq,T}$ by *Corol.* 2, i. e. $BDq,V \,.\, bdq,V :: \frac{SBq}{BDq,T} \,.\, \frac{Sbq}{bdq,T}$, if therefore $\frac{SBq}{BDq,T}$ is $= \frac{Sbq}{bdq,T}$, that is, if $BDq,T \,.\, bdq,T :: SBq \,.\, Sbq$, BDq,V will be $=$ to bdq,V, or the Velocities will be Equal.

Corol. 6. If the Squares of the Periodical Times are as the Cubes of the Radius's, the Centripetal Forces will be Reciprocally, as the Squares of the Radius's, and the Velocities Reciprocally in a Dimidiate Reaſon of the ſame Radius's, and *Vice Verſâ.*

The First, becauſe $DC \,.\, dc :: \frac{SB}{BDq,T} \,.\, \frac{Sb}{bdq,T}$, as before; therefore $DC \times SBq \,.\, dc \times Sbq :: \frac{SB \times SBq}{BDq,T} \,.\, \frac{Sb \times Sbq}{bdq,T}$, and Conſequently, if $\frac{SBc}{BDq,T}$ is $= \frac{Sbc}{bdq,T}$, that is, if $BDq,T \,.\, bdq,T :: SBc \,.\, Sbc$, $DC \times SBq$ will be Equal to $dc \times Sbq$, or $DC \,.\, dc :: Sbq \,.\, SBq :: \frac{1}{SBq} \,.\, \frac{1}{Sbq}$. If $BD,T \,.\, bd,T :: SB|^{\frac{3}{2}} \,.\, Sb|^{\frac{3}{2}}$, or $\sqrt{SBc} \,.\, \sqrt{Sbc}$, it will be the ſame, As it neceſſarily follows from the Former.

Sir Iſ. Newt. Princip. Edit. 2.

The Second, becauſe $\frac{BDq,V}{SB} \,.\, \frac{bdq,V}{Sb} :: \frac{SB}{BDq,T} \,.\, \frac{Sb}{bdq,T}$, as before; Conſequently $\frac{BDq,V \times SBq}{SB} \,.\, \frac{bdq,V \times Sbq}{Sb} :: \frac{SB \times SBq}{BDq,T} \,.\, \frac{Sb \times Sbq}{bdq,T} :: BDq,V \times SB \,.\, bdq,V \times Sb$; if therefore $\frac{SBc}{BDq,T}$ is $= \frac{Sbc}{bdq,T}$, or, which is the ſame, if $BDq,T \,.\, bdq,T :: SBc \,.\, Sbc$, $BDq,V \times SB$ will be Equal to $bdq,V \times Sb$, that is, $BDq,V \,.\, bdq,V :: Sb \,.\, SB :: \frac{1}{SB} \,.\, \frac{1}{Sb}$, and therefore $BD,V \,.\, bd,V :: Sb|^{\frac{1}{2}} \,.\, SB|^{\frac{1}{2}} :: \frac{1}{SB|^{\frac{1}{2}}} \,.\, \frac{1}{Sb|^{\frac{1}{2}}}$. Or, $\sqrt{Sb} \,.\, \sqrt{SB}$, or $\frac{1}{\sqrt{SB}} \,.\, \frac{1}{\sqrt{Sb}}$.

Sir Iſ. Newt. Princip. Edit. 1.

Lastly, It is Infer'd, that all theſe Corollaries Follow in Reſpect of the Periodick Times, the Velocities, and the Forces, with which Bodies Deſcribe Similar Parts of any Similar Figures, and which have Centers in a Similar Poſition, if the Demonſtration of what foregoes is Apply'd to theſe Caſes, and the Application is made by Subſtituting an Equable Deſcription of Areas for an Equable Motion, and the Diſtances of Bodies from the Centers for Radius's.

Schol. Propoſ. 4.

We are farther in the Scholium of this Propoſition told, that the Caſe of the Sixth Corollary obtains in the Heavenly Bodies, according to Sir *Chriſtopher Wren*, Dr. *Hook*, and Dr. *Halley*.

Moreover that, by the Aſſiſtance of this Demonſtration, we may Collect the Proportion of the Centripetal Force to any Force, which is known, as that of Gravity. For if a Body is Revolv'd by the Force of it's Gravity in a Circle Concentrical to the Earth, this Gravity is it's Centripetal Force, but from the Deſcent of Heavy Bodies the Time of one Revolution is Given, and an Arc Deſcrib'd in any Given Time is had by an Inference, which is Deriv'd from this Propoſition, Namely, that the Arc, which a Body Deſcribes in any Given Time, whilſt it Revolves Uniformly in a Circle with a Centripetal Force Given, is a Middle Proportional betwixt the

Diameter of the Circle, and the Deſcent of the Body perform'd with the ſame Given Force, and in the ſame Time, that is, ſince $DC \,.\, dc :: \frac{BDq}{SB} \,.\, \frac{bdq}{Sb} :: \frac{BDq}{2SB} \,.\, \frac{bdq}{2Sb}$, therefore $2SB \,.\, BD :: BD \,.\, DC$, or $DC = \frac{BDq}{2SB}$, and Conſequently, DC is to the Force of Gravity as $\frac{BDq}{2SB}$ is to the Space, which an Heavy Body Deſcribes by it's Fall in the ſame Time.

We are alſo Inform'd from the Preſent Scholium, that this Propoſition may be Demonſtrated another Way; Let a Polygone of what Number of Sides ſoever be Deſcrib'd in a Circle, and if the Body, by Moving with a Given Velocity in the Sides of the Polygone, ſhou'd be Reflected from the Circle at each of the Angles; The Force, with which it Strikes upon the Circle in each Reflection, will be as it's Velocity, and therefore the Sum of the Forces in a Given Time will be as that Velocity, and the Number of Reflections conjunctly, that is, (if any Polygone is Particularly Given) as the Length Deſcrib'd in that Time, and the ſame Length Divided by the Radius of the Circle, or as the Square of that Length Divided by the Radius, and conſequently, if the Sides of the Polygone are Diminiſh'd to Infinity, ſo as to Coincide with the Circle, as the Square of the Arc Deſcrib'd in a Time Given Divided by the Radius; And this is ſaid to be the Force, with which a Body Urges or Preſſes upon the Circle, and to this is Equal the Contrary Force, by which a Circle conſtantly Repells the Body towards the Center. There is likewiſe another Demonſtration of this Propoſition in the Second Edition of theſe *Principles*, which is Collected and Form'd from *Prop.* 2, and *Corol.* 2. *Prop.* 1, as alſo from *Corol.* 4, of the ſame *Prop.* and from *Lem.* 7, all which have been ſeverally Conſider'd.

The Velocities are ſuppos'd to be as the Arcs they Deſcribe, which afterwards is Contrary to the Corollaries.

§. 10. This being the Chief Propoſition, on which the Revolutions of the Heavenly Bodies Depend, as Explain'd by this Philoſophy, we ſhall be the more Minute in the Examination of it; It is therefore Firſt ſuppos'd, that Two Bodies Move in Different Circles, ſo that the Arcs, *BD*, *bd*, ſhou'd be Perform'd together, and that thoſe Arcs are as the Velocities, with which they are Deſcrib'd, which we ſhall afterwards conſider, And ſhall only ſay at Preſent, that as the Arcs *BD*, *bd* are Perform'd at once, according to the Propoſition, their Circles, which they Repreſent, ſhould be ſo likewiſe, whereas all the foregoing Proportions in the Corollaries ſuppoſe the Periodical Times Different, Contrary to the Propoſition, which ſuppoſes Them the ſame.

Projectile Forces in Tangents are likewiſe here ſuppos'd, but not Prov'd.

§. 11. The Second Thing Preſum'd is, that, by a Sole *Innate* or Projectile Force, the Bodies, *B*, *b*, wou'd Deſcribe the Tangents *BC*, *bc*, and therefore the Centripetal Forces are thoſe, which perpetually Draw the Bodies from the Tangents. In Anſwer to which, it is Alledg'd, that we have already Inquir'd into the Projectile Force, which from whence it ſhou'd be deriv'd into a Paſſive Matter, as we ſaid, we could not Imagine, unleſs from Almighty God himſelf, or from the Will and Pleaſure of the Philoſopher, both which were Conſider'd, but now it ſeems by one word only Introduced of *Innate*, the whole Difficulty is ſolv'd, if that is meant by *Vis Inſita*, for there is no other Senſe Remaining of it; If ſo, how is it poſſible to Conceive, that Matter, which is abſolutely *Paſſive*, ſhould be *Naturally* Endued with a Projectile, or indeed with any Force?

Sir I. Newt. Princip. Def. 3.

'Tis true the *Vis Inſita* of Matter is Defin'd to be the Power of Reſiſtance, by which every Body, as much as in it lies, Perſiſts in it's State of Quieſcence, or Motion Uniformly *in Directum*; Therefore the *Vis Inſita* at the moſt is only the Perſeverance of a Body in that State, in which it is; But the Queſtion here is, how that State of Motion or Reſt is Produced in Unactive Matter, which is not Accounted for; And in General it may be ſaid, that the Perſeverance in a State cannot be *Innate* to Matter, unleſs upon a Suppoſition of Reſiſtance or Action in it, and which is Affirm'd in the Explanation of the Preſent Definition to be the Proper Inertia of it, by which it is ſaid, it comes to paſs, that every Body is difficulty Diſturb'd from the State in which it is; which is ſomething Singular indeed, that a bare Inertia of Matter, which ſuppoſes no Action at all, and that it is Intirely made up of Solidity, Extenſion, Diviſibility, and ſuch kind of Properties, which Include not the leaſt Activity in them, ſhou'd be Endu'd with a Poſitive Action, or a Poſitive Reſt, and in both Caſes with a Reſiſtance to the being Diſturb'd from the State, in which it is; Tho' the Perſeverance of each State does not here properly come into the Account, but how that State is Introduced upon it, which cannot be any Ways conceiv'd, how it ſhou'd be, if Matter is only Solid, Extended, Diviſible, Figur'd, and in General conſiſts of ſuch Qualities, which neither Have, nor can Infer, any Action in Them; Beſides which, if Perſeverance is a Reſiſtance to the being Diſturb'd, there is, as we ſaid, an Action in the Reſiſtance, that is, in the Inertia; or Matter is ſuppos'd to be Active and Unactive at the ſame Time.

Supposing yet this Projectile Force, it is again Imagin'd, that it proceeds in the Tangents, *BC*, *bc*, but it is not from thence Evident, that it will proceed in a Second Tangent Drawn from *D* and *d*; For if the Centripetal Force is Capable of Subdueing the Projectile, ſo as to Draw it to *D* and *d*, how the Projectile Force ſhou'd again Conquer and Subdue the Centripetal, ſo as to make the Projectile proceed in a Second Tangent, is Inconceivable; And the ſame may be ſaid of a Third, or a Fourth Tangent *in Infinitum*.

The Centripetal Forces, and the Proportions of them not Prov'd.

§. 12. The Third Thing Preſum'd is, that the Centripetal Forces are to one another in the Firſt Reaſon of the Naſcents, *CD*, *cd*, and that they Tend to the Centers of the Circles, by the Second Propoſition, becauſe the Areas Deſcrib'd by the Radius's are ſuppos'd Proportional to the Times; As to the Naſcent and Evaneſcent Reaſons, they have been already Conſidered and Refuted, and that *CD*, *cd* Tend to the Centers of the Circles is not Evident from the Second Propoſition, Firſt, becauſe that Propoſition is not Prov'd as we have before Obſerv'd, and in the next Place, becauſe the ſame Propoſition only Alledges, that Every Body, which, when it is Mov'd in any Curve Line and the Radius is Drawn to a Certain Point, Deſcribes Areas about that Point Proportional to the Times, is Urg'd by a Centripetal Force Tending to that Point; Whereas the Centripetal Forces *CD*, *cd* Tend to no ſuch Point, but Act in Directions Parallel to *BS*; 'Tis true *C*, when in *D*, Approaches nearer to *S* the Center, But it is not by a Force, which is Centripetal, for then it wou'd be Urg'd from *C* to *S*, but by an Imaginary one Aſſum'd by the Philoſopher, which Preſſes Side-ways and Parallel, becauſe it beſt ſuits the Preſent Scheme and Reaſoning.

The Similar Triangles aſſumed in this Demonſtration not Evinc'd.

§. 13. After this it is Deſired, that *tkb* ſhould be Similar to *DCB*, and then by Lemma the 5th and 11th the Preſent Propoſition is Concluded.

As to what Reſpects thoſe Lemmas, they have been before Conſider'd and Examin'd, in the *Method* of *Naſcent* and *Evaneſcent Reaſons*; and as to Similar Figures, where the Curves are Different, which enter into their Compoſition, it is a *Poſtulatum*, which it is Impoſſible to Grant, ſince, altho' the Angle *bkt* ſhould be Equal to the Angle *BCD*, yet *kbt* will not be Equal to *CBD*, unleſs we can ſuppoſe, that *BD*, Drawn by the Radius *SB* from the Point *b*, has the ſame Curvity and Direction with *bd*, Deſcrib'd by the Radius *Sb* from the ſame Point *b*, which is Contrary to Common Senſe and Experience.

On the other Hand, it is not Prov'd, that *kt*, falling upon any Part of the Circle *bt*, will make an Angle Equal to that, which is Comprehended betwixt *CD* and *BD*, for where the Curvities of Unequal Circles differ in every Point, it is not Imaginable, nor can it be Conceiv'd, how Lines Drawn Parallel to the Radius's of thoſe Circles ſhoud ever make Equal Angles. If yet it is ſaid, that *BD*, *bt*, are to be Conſider'd as Right Lines in the laſt Reſult, then *BD* and *bt* will Coincide with *BC* and *bk*, and Conſequently there will be no Triangles, and therefore no Similar ones.

The Firſt Corollary Examin'd, and the Proportion it aſſerts Refuted, and why the Moments, with which all Concentrical Circles or Similar Arcs are Deſcrib'd, are Equal, and Leſſer Circles are more Difficulty Deſcrib'd than Larger.

§. 14. We ſhall now Grant theſe ſeveral Preſumptions, and that $DC . dc :: \frac{BDq}{SB} . \frac{bdq}{Sb}$, The Corollaries yet, which are Drawn from hence, will deſerve to be Conſider'd.

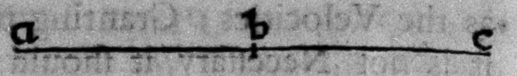
The Firſt of which is, that the Centripetal Forces are as the Squares of the Velocities, divided by the Radius's of the Circles, that is, $DC . dc :: \frac{BDq,V}{SB} . \frac{bdq,V}{Sb}$, In which Caſe, the Velocities are ſuppos'd to be as the Arcs, which are Deſcrib'd; And in General this Doctrine takes it for Granted, and makes it a Fundamental Maxim to it's Reaſonings, that Every Space, which is Deſcrib'd, is Compounded of the Time and the Velocity, which are us'd in it's Deſcription, and therefore, the Times in the Preſent Caſe being Equal, the Spaces Deſcrib'd, or the Arcs, will be as the Velocities; Granting therefore this to be ſo for the Preſent in Right Lines, it is not Neceſſary it ſhould be ſo in Curve ones, at Leaſt according to this Philoſophy; Since BD, bd, tho' Deſcrib'd in Equal Times, may not be as the Velocities, becauſe the Centripetal Forces CD, cd have their Effect, which will Interrupt, and Deſtroy that Proportion ſo far, that if the Times are the ſame, and the Spaces BD and bd Equal, yet the Velocities may not be; becauſe, where the Centripetal Force is Greater in CD than in cd, it may Require a Greater Velocity to Perform an Equal Arc in BD than in bd, tho' the Times are Equal; for it muſt want a Greater Force to turn a Point, into a Greater Curvity BD than into a Leſs bd, from it's Rectilineal Motion in BC, bc, becauſe D Declines more from C than d from c, or, which is the ſame, the Centripetal Force is Greater in D than in d, and therefore will demand Proportionably a Greater Degree of Velocity or Force to Actuate and Impell it in the Circle.

THIS is the more Probable, becauſe from hence the Moments, with which all Concentrical Circles are Deſcrib'd, will become Equal, as in all Reaſon and Senſe they ought to be; for how Abſurd is it to Think, that Motions, which begin and end at once, and are carry'd on in all the Intermediate Parts Uniformly, ſhould not be Generated by Forces, which are Æquipollent? Which if ſo, the Arcs will not be as the Velocities, but in a Compound Reaſon of the Velocities, and the Centripetal Forces, and ſuppoſing BC, bc, to Repreſent the Velocities, and CD, cd the Centripetal Forces, $BD \,.\, bd :: BC \times CD \,.\, bc \times cd$; and in Reſpect of the Velocities and Centripetal Forces in Similar Arcs, BD, bt, it will be $BC.bk::kt.CD$, ſuppoſing bk the Velocity, and kt the Centripetal Force of bt; So that if we take BD, bd, as Two Equal Arcs, both the Arcs themſelves, and every Point, which Forms them, will be of very Different Natures, and not Equal in any Particular, excepting that perhaps they are Meaſur'd by the ſame Aperture of the Compaſſes; ſince every Imaginable Equal Portion of the Arcs BD, bd, and the Arcs themſelves, conſiſt of Velocities and Centripetal Forces, which entirely Differ from each other, and we may as well ſay, that an Inch Line is Equal to an Inch Square or Cube, becauſe they ſeem to be ſo in Extent, or by the Meaſure of the Compaſſes, as that BD is Equal to bd for that Reaſon; For by what foregoes they are Different in their Nature and Conſtitution, and as much Slower, as the Velocity in BD is, than that in bd, ſo much is it the more Compact and Stronger, and as much Quicker, as the Velocity in bd is, than that in BD, ſo much is it the more Expanded and Dilated, or Weaken'd; that is, the Points Impell'd in BD are Heavier, and in bd Lighter, the Centripetal Force in the One being Greater than that in the Other: And this is ſaid in Relation to the Deſcription of Circles themſelves, Abſtracted from and without Conſidering Bodies Revolv'd in them, which may poſſibly be the Reaſon, why Leſſer Circles are Deſcrib'd with Greater Difficulty than Larger from the ſame Center.

A new kind of Force or Velocity Propos'd even in Right Lines, which may be Different in the ſame Spaces, the Time being the ſame, and the ſame in Different ones, and is Agreeable to and Confirm'd by Nature.

§. 15. AND This brings me to ſpeak of a Certain Kind of Velocity, even in Right Lines, which this Philoſophy has not ſo much as thought of, and which may be Equally Preſum'd, as well as the Preſent, which Depends upon it's being in a Reciprocal Proportion of the Times, in which it is Perform'd, ſuppoſing the Space the ſame, in which it Acts; that is, a Simple Velocity is Deſcrib'd in a Certain and Determin'd Time, a Double Velocity in Half that Time, a Triple in a Third Part of it, *&c.* On the Contrary, Half ſuch a Velocity will be in Double the Time, and a Third Part in a Triple of it; whereas from the *Geometry* of *Solids*, it is Evident, that the Proportions of Velocity or Force may be Infinite in the ſame Time, and the ſame Space, and we may add on the Contrary, that the Proportions of Time and Space may be Infinite, where there is the ſame Force or Velocity: That is, there may be the Same Line Deſcrib'd, which, tho' in Length it is the Same, ſhall be Capable of Different Values, Quantities, or Eſtimations, and Different Lines Deſcrib'd, which, tho' Different in Length, ſhall be Capable of the Same Values or Denominations, that is, ſuppoſing the Lengths of the Lines to Expreſs the Times, and the Values or Denominations of them the Velocities.

Thus it will not be deny'd, but that the Line *ab* may be twice Deſcrib'd in the Time Expreſs'd by *ab*, whilſt the ſame Line *ab* may be only once Deſcrib'd by a Different and a Slower Velocity; if therefore what is Deſcrib'd in Length is Confer'd upon the Force, that is, if there is a Double Force in every Part of *ab*, where it would have Deſcrib'd a Double Line for a Single one, in every Part of it, where it would only with a Single Force have Deſcrib'd a Single one, it will be the ſame, as the Repreſenting to us Different Actions or Forces in the ſame Points of Space, and in the ſame Time; the Eaſineſs of which Conception is Manifeſt, from Preſſing a Finger upon a Table with Different Degrees of Force, or from the Action of Fire, and of Electricity, or the Magnet, or any other Action, Perform'd in the ſame Time and Space, which yet are Different in their Natures and Activity; The ſame may be ſaid of Gravity, for if we take a Globe of Lead, and another of Cork, and ſet Them upon a Plane, Nothing can be more Evident, than that the Gravitating Action of the One, and of the Other, is Different in the ſame Time, and in the ſame Space.



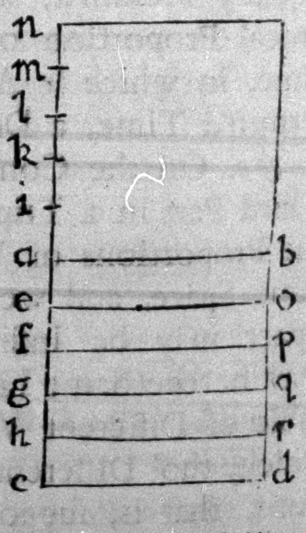
On the other Hand, as there may be Lines Deſcrib'd, which are in Length and Time the ſame, tho' Different in their Values or Denominations, ſo may there be Lines, which are Different in Length, Deſcrib'd in the ſame Time, and yet their Values the ſame; For if *ab* may be Deſcrib'd Twice in the ſame Time by a Double Velocity, whilſt the ſame Line is Deſcrib'd Once by a Single one, and the Double Velocity may be Confer'd upon a Double Force in each Point of *ab*; For the ſame Reaſon the Double Force Compreſs'd in *ab* will be Equal to the Double Velocity, which repeated *ab* Twice, and which is Equal to *ab*, *bc*; All the Difference, which will be, is, that the Action or Force is Compreſs'd in the one Caſe into *ab*, and Diffus'd or Dilated in the other, where it Scatters or Diſperſes it's ſelf, as far as *c*; Notwithſtanding which, *ab* in ſuch a Circumſtance will be Equal to *ac*; and thus it is in the Gravitating Force, where Gold is to Water, as 19 to 1, if therefore we take 19 Times as much Water as Gold, their Gravitating Forces will be Equal, tho' their Spaces are Different, and as 19 to 1.

And this is in a great Meaſure what we Intended in the *Geometry* of *Solids*, or of *Matter*, in which we Endeavour'd to Conform Mathematicks to Nature, and not to the Arbitrary Abſtractions of the Mind, Deriv'd originally from the Italick Sect of Philoſophers, who made all Things to conſiſt in Numbers and Abſtractions, and from the Notions in Logicks of Quantity and Extenſion, and from thence Spread into all the *Elements* of *Geometry*, as well as into all the *Syſtems* of *Philoſophy*, which have been Propos'd to us from the Times of *Pythagoras* the *Geometer*, and *Ariſtotle* the Great Inventor of *Logicks*, to the Preſent Age we Live in.

A new Generation of Mathematick Quantities Conformable to the above ſaid Notions, and Correſponding with Nature, as it Really Exiſts.

§. 16. And that the Generation of Mathematick Quantities, by Drawing a Cube into a Line, *&c.* and from thence Forming both Lines, Squares, and Cubes, Each of them of Different Dimenſions from what are vulgarly Receiv'd, is Agreeable to this Reaſoning we have already ſhewn in the ſame *Geometry* of *Solids*, or of *Matter*, and ſhall here farther Explain.

Let *ab* be one Conſtant and Determined Line, which is Produced by a Certain and Fixt Degree of Velocity; In the flowing of the Point from *a* to *b*, the only Reaſon of that Line's being Deſcrib'd is, that *a* paſſes thro' every Point of it to *b*, let the Velocity be what it will: From which Generation of *ab* it muſt be Acknowledged, that wherever a Point, as *a*, paſſes, it Produces Length, and for the ſame Reaſon, wherever a Line paſſes Parallel to it's ſelf, it Produces Breadth, and wherever a Surface or Breadth paſſes Parallel to it's ſelf, it Produces Space or Depth; The Queſtion is, whether a Cube carry'd Parallel to it's ſelf, according to the Direction of the ſame Line, may not Produce a Cube of a Different Value, Depth, or Space, which we Affirm it may.



Thus let *abcd* Repreſent the Side of a Cube, it is Evident, that if *ab* was Conſider'd as the Side of a Square, (which Square ſhou'd follow the Motion of it's Side *ab*, and be Perpendicular to the Plane *nb*) and ſhou'd paſs thro' the ſeveral Diſtinctions in an, from a to i, k, l, m, and n, ſuch a Motion of the Square of ab would Produce the Common Cube or Solid of the Mathematicians; As therefore ab before Repreſented the Square of it, Let eo, fp, gq, hr, cd Repreſent the Squares of which they are the Sides, it is Manifeſt, if $abcd$ is now Mov'd upwards from a to n, at the ſame Time that ab has paſſed thro' the ſeveral Points of an, and conſequently has Deſcrib'd a Cube, eo will have paſſed thro' all the ſame Points, excepting thoſe which lie betwixt m and n, and conſequently will have Deſcribed another Cube, excepting what Remains to be Accompliſhed betwixt m and n, if eo therefore Riſes to n, it will have Perform'd a Second Cube, as ab had done before, and by the ſame Argument fp, gq, hr, cd, will Perform or Deſcribe a Third, Fourth, Fifth, or Sixth Cube, when they arrive Reſpectively at n; From whence it will follow, that the Cube $abcd$ multiply'd into the Line an will be a Cube, whoſe Every Square after ſuch a Multiplication will be as much a Cube, as Every Parallel Superficies of a Common Cube is a Square, and by the ſame Methods of Generation: And the like Kind of Reaſoning obtains in the Multiplication of this Second Cube into the ſame Line an, *&c.*

Nor can it be oppos'd to this Generation of Mathematick Solids, to the *4th*, *5th*, *6th*, or *100th* Dimenſion, or to Infinity, that it is only Deſcribing the ſame Space over-again, without any conſequent Effect, ſince, if the Line ab in it's Motion, according to the Direction of an, Produces a real Square, which is Conſtant in that Space, in which it is Produced, for the ſame Reaſon the Lines eo, fp, gq, &c. will; that is, if the one has an Effect, which is Conſtant, the other will, or elſe they will all Equally have none, and the Line ab Multiply'd into an will not ſo much as Produce a Square.

We ſhall only therefore farther obſerve upon this kind of Geneſis, that the Reaſon of the foregoing Objection ſeems to lie in this, that Men have already form'd in their Minds their Idea of Length and Breadth, or of Space in General, as actually Exiſting in Nature, and which becomes Unvariable, whatever paſſes thro' it; Thus, Albeit Ten Thouſand Waves ſhould ſucceed each other thro' the ſame Space, the Space will ſtill remain Unalter'd, and conſequently it is thought, if a Million of Squares are carry'd Parallel to themſelves thro' the ſame Cube, or ſo many Lines thro' the ſame Square, both the Square and the Cube will be ſtill Conſtant and Unvary'd.

But if we Examine truly into this Sort of Arguing, the Caſe will appear to be Extreamly Different; for in the Firſt Inſtance, there is a ſtanding Meaſure of Space originally Fixed in the Mind, and which will be Immutable, whatever paſſes thro' it, but in the Second, namely, in the Generation of Mathematick Quantities, there is nothing ſuppoſed before the Production of thoſe Quantities, not ſo much as Length or Breadth; and conſequently, ſince Length is Produced, where there was no Length before, and Breadth, where there was no Breadth, *&c.* for the ſame Reaſon there may be more Dimenſions than Three Produced in the ſame Abſtracted Space, which were not there before, namely, by ſuch Actual Productions as are already Deſcrib'd; For Ten Dimenſions may as well Exiſt together as One, ſince they all of them Exiſt in nothing but Themſelves, that is, Five, Six, or Ten Dimenſions do not Exiſt in Three Dimenſions, no more than Three in Two, but they Exiſt in Themſelves, where Nothing of Them before Exiſted.

The Corollaries from this Doctrine.

§. 17. *Corol.* 1. From hence it follows, That as a Drawn into ac Produces a Line, ſo ca on the Contrary, Drawn into the Point a, ſo as Every Point of it ſhould paſs Succeſſively thro' a, will Produce in it a Quantity Equal to a Line.

Corol. 2. Likewise, if ca is Drawn Succeſſively thro' each Point in an, namely, a, i, k, l, m, n, and thoſe Points are Infinite, there will be a Line Produced in each Point, and conſequently, a Square Produced in the Line.

Corol. 3. Also, if ab is carry'd Parallel to it's ſelf, According to the Points a, i, k, l, m, n, it will Produce a Square, and if eo, fp, gq, hr, cd, are Succeſſively made to paſs thro' the ſame Points, and Parallel to Themſelves, they will Produce a Cube within the ſame Limits of the Square bn.

Corol. 4. Therefore every Point in ſuch a Cube will be Equal to a Line, every Line Equal to a Square, and every Square Equal to a Common Cube or Solid, and the Cube will be a Dimenſion of the Fourth Power.

Corol. 5. If, after this Cube is Produced, it is again multiply'd into the ſame Line an, ſince ab, which was a Line before, is now a Square, if it is Drawn into an, the

Square *bn* will be Equal to a Cube; And ſince *eo*, *fp*, *gq*, *hr*, *cd* are Succeſſively drawn into the ſame Line *an*, the Square *bn* will be Equal to the Dimenſion of the Fourth Power, and the Cube will be of the Fifth, in which Every Point will be Equal to a Square, Every Line Equal to a Common Mathematick Solid, and Every Square Equal to a Dimenſion of the Fourth Power, *&c.*

Corol. 6. FROM which it follows in General, according to what we have Expreſs'd in the *Geometry* of *Solids*, *Prop.* 1. *Corol.* 9. *Par.* 1, that m^3, m^4, m^5, m^6, m^7, &c. *in Infinitum* may be Each of them Compreſſed into a Cube, which is the ſame, as to Length, Breadth, and Depth, according to the Ordinary and Common Abſtractions.

WE have only however propos'd this, as a Way of Generating Quantities, which are Different in their Dimenſions, whilſt the Abſtracted Spaces continue the ſame; but that there are in Fact ſuch Quantities conſidered in Mathematicks, is Evident from the Lemma Prefixed to the *Geometry* of *Solids*, and from *Chap.* 4. *§.* 11. of the *Principles* of *Natural Philoſophy*, and Dr. *Wallis*'s *Arithmetick* of *Infinites* there Cited, which is the Foundation of the Preſent Celebrated *Doctrine* of the *Infinite Series*.

FROM whence, inſtead of the *Elements* of *Geometry*, which we poſſeſs, a Thouſand and a Million of *Euclids* might be Form'd, and the *Pomœria* of *Mathematicks* Enlarged without Bounds, and made as Univerſal and Comprehenſive as *Algebra* it ſelf. And that ſuch a Generation of Quantities is Agreeable to Nature is Plain, in which we find an Immenſe Number of Various and Different Bodies Exiſting in the ſame Space, as Gold, Lead, Marble, Wood, Water, Air, Fire, Light, and Æther, and the ſeveral other Infinite Species and Kinds of Bodies, which lie Intermediate to them, whoſe Different Conſtipations of Action, or whoſe Expanſive and Contractive Forces, may be Repreſented by theſe Different Extenſions, which can never be Reduced to an Unvary'd and Abſtracted one of Mere Length, Breadth, and Thickneſs: If therefore the Preſent Philoſophy is miſtaken in it's Notions of Velocities being always Reciprocal to the Times, and in it's Conception of Space, it's whole Reaſoning in This and the Subſequent Corollaries is Falſe, which ſuppoſes the Common and Vulgar Abſtractions of both.

The Second Corollary of the Preceding Propoſition Examin'd.

§. 18. THE Second Corollary from this Propoſition is, That the Centripetal Forces are Reciprocally as the Squares of the Periodical Times Divided by the Radius's; which Depends upon this Propoſition, that the Periodical Times are in a Reaſon Compounded of a Reaſon of the Radius's Directly, and of a Reaſon of the Velocities Inverſely, that is, $BD, T \,.\, bd, T :: \frac{SB}{BD, V} \,.\, \frac{Sb}{bd, V}$, and therefore, ſince it Aſſumes the Receiv'd Abſtractions of Velocity and Space for certain Maxims, is liable to the ſame Confutation.

The Third, Fourth, Fifth, and Sixth Corollaries.

§. 19. As the Third Corollary entirely Reſts upon what foregoes, ſo there is no Occaſion for any Conviction of the Untruth of it, and as the Fourth, Fifth, and Sixth Corollaries Inſiſt upon the Proportions of the Third, and are only Affirmations of the ſame Thing, by Multiplying, Dividing, Inverting, and Alternation, according to the Common and Fixed Rules in Mathematick Proportions, it will be unneceſſary to Enter into a more Critical Examination of them.

Objections againſt the Sixth Corollary obtaining in the Heavenly Bodies.

§. 20. AFTER a particular Inquiry into this Propoſition and the Corollaries of it, we ſhall conſider what is offered to us in the Scholium it ſubjoins, Namely, that the Sixth Corollary obtains in the Revolutions of the Heavenly Bodies, even according to what our own Country Men, as it is ſaid, have Collected a-part from each other, to wit, Sir *Chriſtopher Wren*, Dr. *Hook*, and Dr. *Halley*, In Anſwer to which we ſhall ſay;

FIRST, That the Proportion of this Corollary is not Prov'd, unleſs upon Abſtractions, which are Arbitrary, Uncertain, or Falſe.

SECOND, When this is Apply'd to the Planets, they are Conſider'd or Imagin'd to Conſiſt of a like Homogeneous Matter, whoſe Weight is Proportional to it's Quantity, which Notion has been already Examin'd into, whereas by the Nature of all the Matter, which Surrounds us, it is more Reaſonable to think it is Various and has Different Forces of Gravitation Peculiar to it, and conſequently, that Each Planet has, beſides what is Deriv'd from the Proportion of it's Greater or Leſs Diſtance from the Center.

THIRD, This Reaſoning is ſaid to be Confirm'd by the Obſervations made in the Heavens by Aſtronomers.

How it is Confirm'd by the Obſervations made in the Heavens by Aſtronomers.
Sir Iſ. Newt. Princ. Lib. 3. Phænom. 1, 2. Edit. 2.
Dr. Gregory's Aſtronom. Prop. 21. §. 4. Lib. 1.

§. 21. SINCE Firſt, the Motion of the Secondary Planets Revolving about any Primary one is ſo Adjuſted, that the Squares of the Periodick Times are in the ſame Reaſon with the Cubes of the Diſtances of the ſaid Planets from the Center of the Primary.

THUS in the Satellites of *Jupiter*, where the Periodick Times of the Innermoſt, the Second, the Third, and the Outermoſt, are Reſpectively, as $1\frac{3}{4}$, $3\frac{3}{5}$, $7\frac{1}{8}$, and $16\frac{3}{4}$ nearly, and their Diſtances, as $5\frac{2}{3}$, 9, $14\frac{1}{3}$, and 25; The Square of the Periodick Time of the Innermoſt, to wit 3, is to 13 the Square of the Periodick Time of the Second Satelles, as 170 the Cube of the Diſtance of the Innermoſt, to 736 the Cube of the Diſtance of the Second from the ſame Center.

IN like manner 3 is to 51 the Square of the Periodick Time of the Third Satelles, as 170 to 2890 the Cube of the Diſtance of this Third from the ſame Center of *Jupiter*.

ALSO 3 is to 280 the Square of the Periodick Time of the Outmoſt Satelles, as 170 to 15800 the Cube of the Diſtance of the ſame Outmoſt Satelles; and *ex Æquo* the ſame Reaſon obtains, if any Two other Satellites are Compared with One Another, that is, the Second with the Third, or with the Outermoſt, or the Third with the Outermoſt; And this Reaſon is ſtill more Exact, if the Diſtances and Periodick Times are taken more Accurately.

LASTLY, it is ſaid the ſame happens in the Satellites of *Saturn*, if thoſe Numbers are Aſſumed, which are Expreſs'd in the 15th *Prop.* of this Aſtronomy.

Anſwer to the foregoing Obſervations.

§. 22. FIRST, If therefore we Allow theſe Obſervations to be True, which yet may be Conteſted, as we have ſhewn in another Place, it will only follow, ſince the Principles before are Prov'd to be Falſe, that this Doctrine is no Other than an Ingenious Contrivance of the Mind to ſolve Phænomenons, which were already known, and that theſe Phænomenons are not deriv'd from a Strict, and Mathematick Reaſoning, but that an Hypotheſis is Invented and Pretended to be Mathematick by the Lines and Figures, which it draws, and then Adapted to the Solutions it Propoſes.

SECOND, In Reſpect of the Numbers, thoſe, which are Expreſs'd in the 15th Propoſition, do indeed Agree with thoſe, which are mentioned here excepting in the Diſtance of the Outmoſt Satelles, which is there ſaid to be as $25\frac{1}{3}$, whereas here it is only 25, which will cauſe ſome Difference at Leaſt in the Proportion Aſſign'd upon that Diſtance.

BUT that which is more is, it is not Evident, that the Numbers Alledg'd obſerve the Proportion Requir'd, for the Square of $1\frac{3}{4}$, the Periodical Time of the Inmoſt Satelles is $1+\frac{3}{4}\times 1+\frac{3}{4} =$ to $1+\frac{6}{4}+\frac{9}{16} =$ to $\frac{49}{16} = 3\frac{1}{16}$; Whereas in the Proportion, it is made to be only 3; Likewiſe the Periodick Time of the Second Satelles is $3\frac{3}{5} =$ to $\frac{18}{5}$, and the Square of it $= \frac{324}{25} =$ to $12\frac{24}{25}$, Whereas in the Proportion it is made to be 13; Thus alſo in the Diſtances, $5\frac{2}{3}$ is that of the Innermoſt Satelles, the Cube of which is $\frac{17\times 17\times 17}{3\times 3\times 3} =$ to $\frac{4913}{27} =$ to $181\frac{26}{27}$, which yet the Proportion makes to be 170; The Diſtance of the Second is ſaid to be 9, the Cube of which is $9\times 9\times 9 =$ to 729, which notwithſtanding is in the Proportion Expreſs'd by 736; what therefore can we conclude from ſuch a Reaſoning? Unleſs this, that either $3\frac{1}{16} . 12\frac{24}{25} :: 181\frac{26}{27} . 729$ is the ſame as $3 . 13 :: 170 . 736$, which is Impoſſible, or elſe that the Squares of the Periodick Times are not as the Cubes of the Diſtances, or which is the ſame, that the Periodick Times are not in a Seſquiplicate Reaſon of Them, according to *Corol. 6.*

WE muſt farther Add, that $3 . 13 :: 170 . 736$ is not a Juſt Proportion, unleſs 2208 is Equal to 2210, which are the Products from a Multiplication of 3 into 736, and of 13 into 170.

IT will be unneceſſary to Inquire into the other Proportions having conſidered theſe, ſince they admit of the ſame Reaſoning and Compariſon.

WE muſt likewiſe obſerve, that the Inmoſt Satelles of *Jupiter* is Diſtant from the Center of it's Planet, according to *Caſſini* in his Obſervations thro' a Teleſcope, 5 Semidiameters of *Jupiter* only, the Second Satelles 8, the Third 13, and the Outmoſt

moſt 23; *Townley* and *Flamſtead*, by their Obſervations thro' a Micrometer, do not make the Diſtances much more, but *Borellus* Enlarges them to $5\frac{2}{3}$, $8\frac{2}{3}$, 14, and $24\frac{2}{3}$, in which Obſervations there is the Difference of a whole Semidiameter, that is, according to ſome, of 40000, and according to others, of 25000 Miles at the Leaſt; which is a ſufficient Evidence of the Great Uncertainty of theſe Obſervations, when they neither Agree in the Number of theſe Semidiameters, nor in the Meaſure of the Semidiameters themſelves; However to Aſcertain this Matter, Recourſe is had to Calculations of their Diſtances, from obſerving the Eclipſes of theſe Satellites, and yet here they likewiſe differ, for *Flamſtead* makes them 5.578, 8.876, 14.159, 24.903, and then the Computation of them, from the Periodick Times, fixed them at 5.578, 8.878, 14.168, 24.968, but when this Philoſophy rather choſe to take *Caſſini*'s Obſervations, poſſibly out of ſome Diſguſt to the Former, and when he had Aſſign'd the Diſtances from the Eclipſes of the Satellites to be $5\frac{2}{3}$, 9, $14\frac{23}{60}$, $25\frac{3}{10}$, with Great Facility the Periodick Times were made to Juſtify theſe Obſervations, and accordingly the Diſtances Ariſing from them were found to be 5.667, 9.017, 14.384, 25.299; Let us now therefore take this Laſt Improvement, and tho' the Numbers come pretty near Each other, yet if we conſider, what the Difference of an Unit is, which at the moſt is above 40500, and at the leaſt above 26000 Miles, we ſhall not perhaps ſo readily ſee the Conformity of the Diſtances from the Periodick Times to thoſe which are found by Obſervation; for $5\frac{2}{3} = 5.666$ Subſtracted from 5.667 leaves a Difference of .001 = one Thouſandth Part of 40000 or 26000 Miles, Namely, a Difference of 40 or 26 Miles more according to the Periodick Times than is found by Obſervation, and 17 Times that Number of Miles, that is, 680 or 442 more in the one Caſe than the other in the Diſtance of the Second Satelles, and 40 or 26 Miles more in the Diſtance of the Third Satelles, and the ſame in the Fourth; And yet this is Argu'd upon the Utmoſt Conceſſions, which can be made or are deſir'd by this Philoſophy; For if we take other Obſervations the Difference will be much Greater.

Sir Iſ. Newt. Princip. Edit. 1.

Sir Iſ. Newt. Princip, Edit. 2.

THE Diſtances of *Saturn*'s Satellites, Computed by the Periodick Times, ſtill leſs Correſpond with thoſe, which are Affirm'd from Obſervation, which, meaſured by Semidiameters of his Ring, are $1\frac{19}{20}$, $2\frac{1}{2}$, $3\frac{1}{2}$, 8, 24; The Diameter of his Ring is the Double Seſquiquartan of the Diameter of *Saturn*, or $\frac{9}{4}$ or $2\frac{1}{4}$ of it, which, according to ſome, Contains 67870 Miles, or, according to others, only 43925; If the Firſt, $2\frac{1}{4}$ of that Number will Amount to 152707 Miles, which alſo is had another Way, namely, by adding to 33935 Miles the Semidiameter of *Saturn*, the Diſtance betwixt the Ring and his Body, and the Breadth of the Ring, which are Equal, but the Breadth of the Ring by Obſervation is 21209 Miles, and $2 \times 21209 = 42418$, and the Sum of the Two Numbers will be 76353, the Semidiameter of the Ring, which Doubled Produces the Diameter 152706, the ſame Number nearly as before; If we now take 43925 Miles for the Diameter of *Saturn* $2\frac{1}{4}$ of it is $= 98831$ Miles, the Diameter of the Ring, on the other Hand, add to the Semidiameter of *Saturn* Twice the Breadth of his Ring, and Double that Number, it ought to Produce 98831 the Diameter of the Ring as before, which it does not, but 128761; Let us however here make uſe of the leaſt Number, and the Semidiameter of the Ring will be 49415, that is near 50000 Miles, and in the Former Caſe 76353 Miles, which will be Equal to Unit in the Preſent Calculations.

Hugen's Coſmotheor. P. 102.
Dr. Gregory's Aſtronom. Prop. 15. Lib. 1.
Mr. Whiſton. Prælect. Aſtronom. Pag. 236.

THE Diſtance of the Firſt or Interior Satelles is not Different by the Periodick Times, from what is found by Obſervation 1.95 being = to $1\frac{19}{20}$, likewiſe in the Second Satelles 2.5 = to $2\frac{1}{2}$, but then in the Third Satelles, the Difference betwixt 3.52 and $3\frac{1}{2}$ is $\frac{2}{100}$, or Two Hundredth Parts of an Unit, which is 1526, or at the Loweſt 988 Miles; In the Fourth Satelles the Difference is ſtill more, for betwixt 8.09 and 8 there are Nine Hundredth Parts, that is, a Difference of 6867, or at leaſt of 4446 Miles.

AND thus far the Exceſs has been on the Side of the Periodick Times, that is, the Diſtances are Greater from Them, than what are Confirm'd from Obſervation, but ſo Uncertain and Fallible are theſe Calculations, that in the Fifth Satelles the Diſtance is leſs by Twenty Nine Hundredth Parts from the Periodick Times, than what is obſerv'd, that is, the Difference betwixt 23.71, and 24 is $\frac{29}{100}$, or 22127

Miles, which is more than the whole Breadth of *Saturn's* Ring, or by the Leaſt Computation 14326 Miles, which is near Twice the Earth's Diameter.

If we now Proceed to the Primary Planets, in the firſt Place the Obſervations of *Bullialdus* and *Kepler* Differ from one another, and thoſe of *Bullialdus*, which are the neareſt to the Computations from the Periodick Times, are yet not Correſpondent to Them.

Sir Iſ. Newt. Princip. Lib. 3. Phænom. 4. Edit. 2.

The Middle Diſtance of the *Earth* from the *Sun* is ſuppoſed to conſiſt of 100000 Parts, that is, according to ſome of 81000000, and according to others of 54000000 of Miles; the Reaſon of this Diſſenſion in Opinions Ariſes from the Difficulty of finding the *Sun's* Parallax, from whence Aſtronomers have Variouſly Reported the *Earth's* Diſtance from it, ſome making it no more than 749 Diameters of the *Earth*, whilſt others will have it to be 10000 or 12000, and the Neweſt and moſt Accurate Obſervations fix it at about 5000; however let us take 81 or 54 Millions of Miles, as before ſet down, 100000th Part of which will therefore be either 810 or 540 Miles = to the Unit in theſe Calculations; by *Kepler's* Obſervation, the Diſtance of *Saturn* from the *Sun* is 951000 of theſe Parts, by *Bullialdus's* 954198, ſo that the Latter has 3198 more than the Former, which Amount to 2590380 Miles in the higheſt Computation, and in the Loweſt to 1726920; and the Periodick Times have 392 Parts leſs than *Bullialdus's* Obſervation, which in the higheſt Computation is 317520 Miles, and in the Loweſt 211680: And in the ſame Way and Method may the Diſtances of *Jupiter*, *Mars*, *Venus*, and *Mercury* from the *Sun* be Examin'd and Compared with thoſe, which are Derived from the Periodick Times, wherein we ſhall find the Difference of ſeveral Thouſand Miles conſidered as Minutiæ, which are to be neglected and ſignify Nothing.

'Tis true, when we come to ſuch Large Units of Diſtance, as ſhall Comprehend ſeveral Hundred Miles in them, we may ſeem in our Arithmetical Figures not to vary much from the Obſervations of Aſtronomers, but if thoſe Units have their True Value Aſſign'd them, the Diſagreement will Appear, and we ſhall not be ſo forward to Think, that Thouſands and Millions of Miles are to be look'd upon as a Cypher, in the Real Diſtances of Bodies one from another, for we are not here ſpeaking of the Apparent Diſtances of Them.

Besides, the Diſtance of the *Earth* from the *Sun* is Unaſcertain'd, by the Parts of which the Diſtances of the other Planets are Computed; and in the Secondary ones, whoſe Diſtances are Meaſured by the Diameters of the Primary, thoſe Diameters are as little Determined.

Then, when we come to the Obſervations of theſe Diſtances, the Method of Taking Them, which we have conſidered in another Place, is Lubricous, Difficult, and Fallible, and the Reſults of Them in Fact, Vary, and Diſagree.

If, after This, we Recur to the Periodick Times, They make the Diſtances ſometimes Equal, at other times Greater, and then Leſs, than what is found by the moſt Accurate Obſervations, to which they ſhould always Correſpond, or elſe be always in the Exceſs, or always in the Defect, ſuppoſing thoſe Obſervations were Juſt and True; and if they are not True, it is not more Certain, that the Periodick Times are Right in fixing the Diſtances, when they Agree with Them, than when they Differ from Them.

So that upon the whole we cannot ſee any Demonſtrative Grounds for us to Acquieſce in this Doctrine; we rather think it from hence Appears, that as the Principles of this Philoſophy, which have been Prov'd to be Falſe, were only Contriv'd to ſolve theſe Phænomenons, ſo on the Contrary, that theſe Phænomenons are Fitted by certain Artificial Adjuſtments to Anſwer, as far as Poſſible, ſuch Looſe and Precarious Principles.

We have alſo ſhewn, that it is more Reaſonable to believe, that the Squares of the Periodick Times are not as the Cubes of the Diſtances, or the Periodick Times as the Roots of thoſe Cubes, but that they are as the Diſtances.

The other Demonſtration of this Propoſition not much Different from the Former.

§. 23. As for the other Demonſtration of this Propoſition from an Inſcrib'd Polygone, it does not ſeem to be much Different from the Former, excepting that what the Tangents Perform in the Firſt Caſe is done by Chords in the Laſt, and as there the Body is Drawn down from the Tangent to the Circumference by the Centripetal Force, and by that means is Continually made to Proceed in a

New Tangent, ſo here the Reflexive Force Directs it in a New Chord, and which Reflexive Force likewiſe Urges the Body towards the Center, and is alike Arbitrary and Unproved.

If the Principles Aſſumed by this Philoſophy are Falſe, tho' they ſhould Explain the Phænomenons of the Heavens, it will not excuſe them from being a Mere Contrivance, and without any Foundation in Nature.

§. 24. We might Proceed to the Remaining Propoſitions of this Second Section, and to thoſe of the Third, and ſhew in what Reſpect the Particular Principles, upon which they are Demonſtrated, are Falſe, or Uncertain, as well as how they are ſo in Depending upon others, which have been hitherto Examined, but that being wholly unneceſſary, which yet we could Eaſily do, we ſhall at preſent Wave that Confutation, and only Add, that if the Phænomenons or Theories in the Heavens are Anſwerable to what is Demonſtrated in theſe Sections, it is Evident, that theſe Propoſitions were Artfully Contrived to Give a Solution of Them, by Aſſuming what Sort of Abſtractions this Philoſophy thought were the beſt Adapted to that End; but if ſuch Abſtractions are Erroneous, and the Mind of the Philoſopher Takes and Rejects what he pleaſes in order to Form his Solutions, This, however Mathematical it may Appear, will be no better an Account of the Revolutions of the Planets than *Deſcartes*'s *Vortices*, or the *Striate Particles* in Reſpect of the Loadſtone; for where, as in the preſent Caſe, our Reaſonings are Adjuſted to ſerve a Purpoſe we have in View, let 'em be Mixt with Lines and Angles, or not, They will ſignify no more to the Explaining of Nature, if they are in Themſelves Arbitrary or Falſe, than if we ſhould Aſſume the Abſtracted Notions of Figure, Matter, and Motion, to do the ſame Feat for us, and ſhould Take upon our-ſelves to Shuffle and Combine them at our Pleaſure; The Abſurdity of which Way of Proceeding we have before ſhewn.

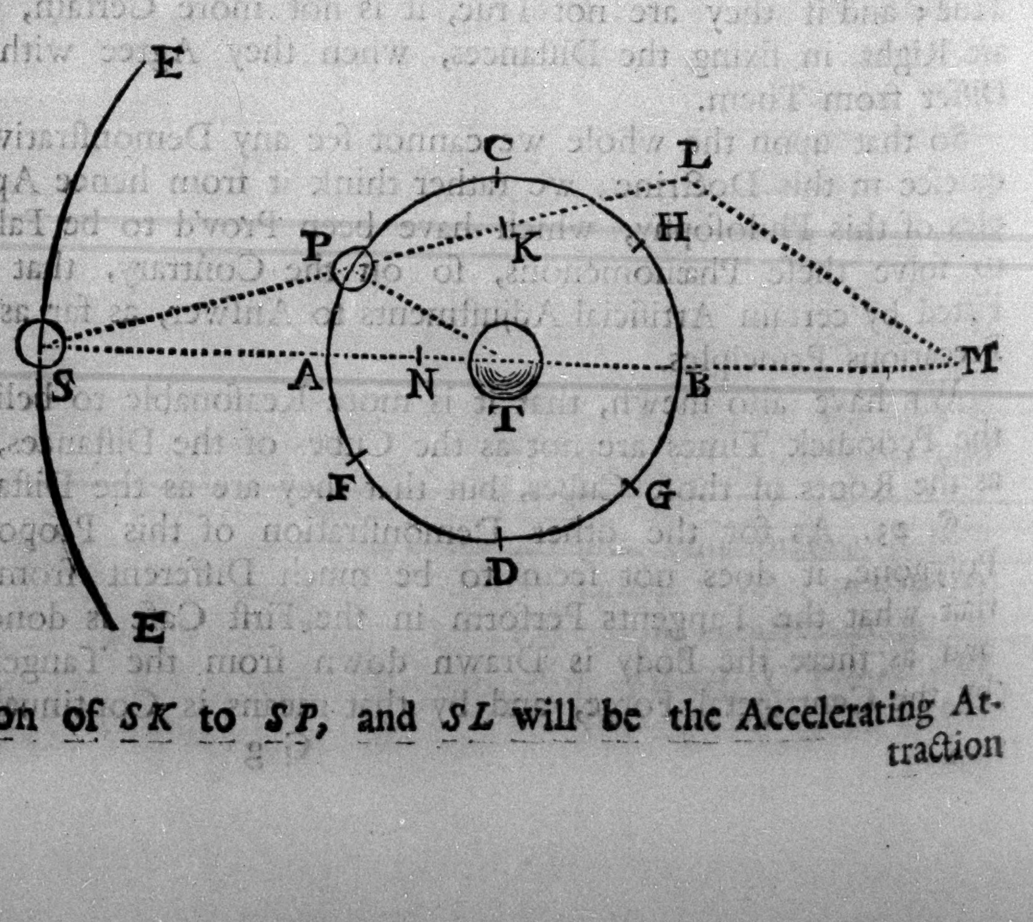
CHAP. V.

Concerning the Theory Propoſed by this Philoſophy for the Solution of the Errors and Irregularities of the Planets.

The Propoſition, upon which the Theory of the Errors of the Planets Depends, Explain'd.
Sir Iſ. Newt. Princip. Prop. 66. §. 11. Lib. 1. Edit. 2. Dr. Gregory's Aſtronom. Lib. 4. §. 1.

§. 1. AFTER having conſidered the General Theory of the Planets, it will be Requiſite to Examine into That, which is brought to Explain the Errors and Irregularities of Them; The Propoſition Alledg'd is, That if Three Bodies, whoſe Forces Decreaſe in a Duplicate Reaſon of their Diſtances, mutually Attract each other, and the Accelerating Attractions of any Two to a Third are to one Another Reciprocally, as the Squares of the Diſtances, and if alſo the Leſſer Bodies are Revolved about the Greateſt; upon theſe Suppoſitions it is Affirm'd and Pronounced, that the Interior Body Revolv'd about the Innermoſt and Greateſt, by Radius's being Drawn to it, will Deſcribe Areas more Proportional to the Times, as well as a Figure more nearly Approaching to the Form of an Ellipſis, which has it's Umbilicus in the Concourſe of the Radius's, if the Greateſt Body is Agitated and Affected by theſe Attractions, than if the ſame Greateſt Body ſhou'd either be Quieſcent, and not Attracted by the Two Leſſer, or being much Leſs or much More Attracted, ſhould be either much Leſs or much More Agitated or Affected.

Caſ. 1. Let the Leſſer Bodies *P* and *S* be Revolved in the ſame Plane about the Greateſt *T*; of which Leſſer Bodies, Let *P* Deſcribe the Interior Orbit *PAB*, and *S* the Exterior *SE*; Let *SK* be the Middle Diſtance of the Bodies *P* and *S*, and let the Accelerating Attraction of the Body *P* towards *S*, in that Middle Diſtance, be Expounded or Set forth by the ſame Line *SK*; Let *SL* be to *SK* in a Duplicate Reaſon of *SK* to *SP*, and *SL* will be the Accelerating Attraction



traction of the Body *P* towards *S* in any Diſtance *SP*; Join *PT*, and Draw the Parallel *LM*, which ſhall Meet *ST* in *M*, and the Attraction *SL* (by *Corol.* 2. of the Laws) will be Reſolv'd into the Attractions *SM*, *LM*, by which means the Body *P* will be Urg'd by a Threefold Accelerating Force.

The Firſt is That, which Tends to *T*, and Ariſes from the Mutual Attraction of the Bodies *T* and *P*; If this Force was only to be Conſidered, the Body *P* would Deſcribe round the Body *T* (whether Unmoved, or Agitated by this Attraction) by the Radius *PT* Areas Proportional to the Times, and an Ellipſis, whoſe Umbilicus is in the Center of the Body *T*, by *Prob.* 6. and *Corol.* 2, 3. *Theor.* 21.

The Second Force, by which the Body *P* is Urg'd, is that of the Attraction *LM*, which, as being Parallel, ſince it Tends from *P* to *T*, if it is Superadded to the Former, will Coincide with it, and by that means will Cauſe, that the Areas ſhould be ſtill Proportional to the Times, by *Corol.* 3. *Theor.* 21. But, becauſe it is not Reciprocally Proportional to the Square of the Diſtance *PT*, it will Compound, together with the Former Force, a Force which Declines from that Proportion, and the more, by how much Greater the Proportion of this Force is to the Former, if other Things are ſuppoſed Equal; and therefore ſince by *Prob.* 6. and *Corol.* 2. *Theor.* 21. the Force, by which an Ellipſis is Deſcribed about the Umbilicus *T*, ought to Tend to that Umbilicus, and to be Reciprocally Proportional to the Square of the Diſtance *PT*, that Compound Force of *PT* and *LM* by Receding from ſuch Proportion will Cauſe, that the Orbit *PAB* ſhould Depart from the Figure of an Ellipſis, which has it's Umbilicus in *T*, and the more, by how much Greater the Deviation is from that Proportion, and therefore, by how much Greater the Proportion of the Second Force *LM* is to the Firſt *PT*, if other Things are Equal.

The Third Force is that of *SM*, which Attracts the Body *P* according to a Line Parallel to *ST*, and will with the other Forces mentioned Compound one, which is no longer Directed from *P* to *T*, and which will ſo far Recede from that Determination, as the Proportion of this Third Force to the Former Forces is Greater, if other Things are Equal, and therefore will Cauſe, that the Body *P* will not by the Radius *TP* Deſcribe Areas Proportional to the Times, and the Deviation from this Proportion will be ſo much the more ſenſible, as the Proportion of this Third Force to the others is Greater; This Third Force alſo will Increaſe the Deviation of the Orbit *PAB* from the aforeſaid Elliptick Form, upon two Accounts, both becauſe it is not Directed from *P* to *T*, and becauſe it is not Proportional to the Square of the Diſtance *PT*; From whence it is Evident, that the Areas are then moſt of all Proportional to the Times, when the Third Force, the other Forces Remaining, is the Leaſt, and that the Orbit *PAB* then Approaches the neareſt to the aforeſaid Elliptick Form, when as well the Second as the Third Force, but eſpecially the Third, is the Leaſt, the Firſt Force Remaining.

Let the Accelerating Attraction of the Body *T* towards *S* be Expreſs'd by the Line *SN*, and if the Accelerating Attractions, *SM*, *SN*, were Equal, Theſe by Drawing or Attracting the Bodies *T* and *P* Equally, and according to Parallel Lines, would make no Change in their Situation to each other, The Motions of thoſe Bodies would be the ſame (by *Corol.* 6. of the Laws) as if theſe Attractions were Abſent or Taken away; And by a like Reaſon, if the Attraction *SN* is Leſs than the Attraction *SM*, it will Take away or Deſtroy the Part *SN* of the Attraction *SM*, and there will only Remain the Part *MN*, by which the Proportionality of the Times, and the Areas, and the Elliptick Form of the Orbit, will be Diſturbed.

Also, If the Attraction *SN* ſhould be Greater than the Attraction *SM*, the only Diſturbance to the Proportionality, and the Orbit, would Ariſe from the Difference *MN*, Thus by the Attraction *SN*, the Third Attraction *SM* is always Reduc'd to the Attraction *MN*, The Firſt and Second Attractions of *PT* and *LM* Remaining Unaltered; And therefore the Areas and the Times do then moſt of all Approach to a Proportionality, and the Orbit *PAB* to the aforeſaid Elliptick Form, when the Attraction *MN* is either None, or as Little as Poſſible, that is, when the Accelerating Attractions of the Bodies *P* and *T*, Made towards *S*, come as near as can be to an Equality, to wit, when the Attraction *SN* is not Nothing, nor yet Leſs than the Leaſt of all the Attractions *SM*, but a kind of Middle Attraction betwixt the

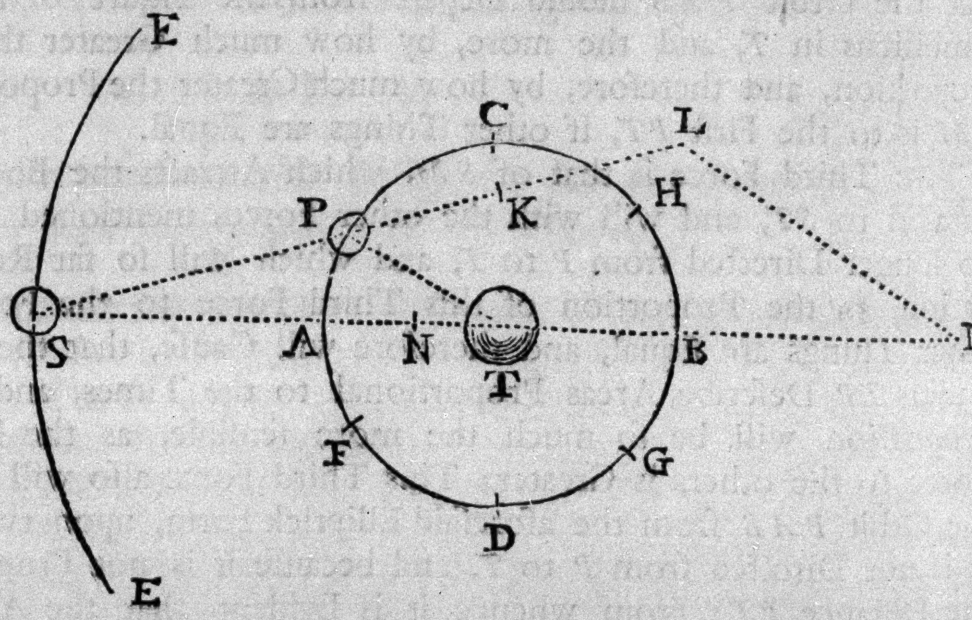
Greateſt and Leaſt of all the Attractions of *SM*, that is, not much Greater nor much Leſs than the Attraction *SK*. *Q. E. D.*

Caſ. 2. Let now the Leſſer Bodies *P*, *S* be Revolved about the Greateſt *T* in Different Planes, and the Force *LM* by Acting according to the Line *PT*, ſituate in the Plane of the Orbit *PAB*, will have the ſame Effect as before, nor will it Wreſt or Turn the Body *P* from the Plane of it's Orbit; but the other Force *NM*, by Acting according to the Line, which is Parallel to *ST* (and therefore, when the Body *S* is Converſant out of the Line of the Nodes, is Inclined to the Plane of the Orbit *PAB*,) beſides the Diſturbance of the Motion in Reſpect of Longitude, which has been already Explain'd, will produce a Diſturbance of Motion in Reſpect of Latitude, by Drawing the Body *P* from the Plane of it's Orbit; and this Diſturbance, in any Given Situation of the Bodies *P* and *T* to each other, will be as that Generating Force *MN*, and therefore will be the Leaſt, where *MN* is the Leaſt, that is, as before, where the Attraction *SN* is not much Greater nor much Leſs than the Attraction *SK*. *Q. E. D.*

The Firſt Suppoſition, that P *will Deſcribe Areas Proportional to the Times, not prov'd by what foregoes.*

§. 2. This Propoſition and the Demonſtration of it is not only the Foundation of the Theory for Explaining the Errors and Irregularities of the Planets, but of That, which is brought to give us an Account of the Flux and Reflux of the Sea, which therefore we ſhall Examine in the ſeveral Diſtinct Parts of it.

In this Demonſtration it is therefore Firſt ſuppos'd, that if *P* was only Attracted by *T*, it would Deſcribe Areas Proportional to the Times, which Doctrine has been before Conſidered, and does not want here a Second Refutation; And yet all which we have Argued upon that Head muſt be ſhewn to be Falſe, before the Preſent Propoſition can in any Senſe be Allow'd to be True.



The Reſolution of the Force SL *into* LM *and* SM *not Evinced.*

§, 3. The other Two Forces Alledg'd are *LM* and *SM*, into which *SL* is ſuppoſed to be Reſolved; what therefore has been in General ſaid againſt ſuch a Reſolution of Forces is likewiſe to be Anſwer'd, before this Reaſoning can obtain; Beſides which, *LM* is Preſum'd to be Drawn Parallel to *PT*, whereas according to that Reſolution of Forces it might be as well in any other Direction, by which means the Line *SM* would become either Longer or Shorter than what is here Expreſs'd, and conſequently, ſince the Attraction of *S* to *T* will be the ſame, to wit, *SN*, the Force *NM* may be Different from what is here ſuppoſed, and therefore will produce Different Effects from Thoſe, which are Concluded from it.

No Reaſon given, why SK *the Middle Diſtance ſhould be the Standard, to which all the other Diſtances ſhould be Exacted.*

§. 4. However, ſince this Philoſophy has Choſen the Parallel Direction to *PT*, becauſe it is the beſt ſuited to it's Deſigns, we ſhall now Conſider it, as Propoſed to us; in order to Produce which, *SL* to *SK* is Taken in a Duplicate Proportion of *SK*, the Middle Diſtance to *SP*, which is any Diſtance Aſſign'd of *P* from *S*; whereas it is not Evident, why the Middle Diſtance ſhould be Aſſum'd in Preference to any other, ſo as to be a Standing Rule, to which the Reſt ſhould be Refer'd or Compared; Since, when the Body is at the Greateſt or at the Leaſt Diſtance, there is Nothing in the Nature of the Thing, which ſhould Exclude it from the ſame Pretenſions of being the Standard of the others, Excepting that of Greater or Leſs, which Equally obtains againſt the Middle Diſtance, ſeeing it is Leſs than the Greateſt Diſtance, and Greater than the Leaſt.

Granting the Parallel Direction LM, *and the Middle Diſtance* SK, *this Reaſoning is liable to another Objection.*

§. 5. GRANTING yet this Hypotheſis of the Middle Diſtance being the Standard, to which all the Reſt ſhould be Exacted, which is no other than an Arbitrary one, and that *LM* is one of the Forces into which *SL* is Reſolved, it is far from being Apparent, that a Parallel Force, which is ſuppoſed to Act from *L* to *M*, ſhould Act from *P* to *T*, that is, that Two Different Points, as *M* and *T*, ſhould be the ſame; If *LM* is on the other Hand only an Expreſſion of the Force Acting from *P* to *T*, it is ſomething Extraordinary, that a Force, which Acts Directly from *P* to *S* according to this Hypotheſis, ſhould exert it ſelf in any Part of it from *P* to *T*, unleſs we can Imagine, which is at preſent Incomprehenſible, that a Force, which is deem'd to Act one Way, ſhall be Capable in any Degree of Acting a Contrary; For if *P* to *S* is a Determined Force, as it is ſuppoſed to be, if it can Act from *P* to *T*, it muſt be by Enlarging the Force from *P* to *S*, and Taking ſo much from it by a Contrary Force from *P* to *T*, which ſhall make it Equal to the Determined one from *P* to *S*, which is no more than making the Force what it was before, and Annexing an Arbitrary Addition and Subtraction of a Foreign one, which deſtroy each other. If, notwithſtanding, we could Allow of what has been hitherto Diſputed, we ſhould have this Advantage from it, of Confirming that, which we have ſo often Contended for in our *Geometry* of *Solids*, and in this *Philoſophy*, that there may be Various Forces or Velocities Conceiv'd in the ſame Inſtant of Time, and in the ſame Line, Surface, or Solid; for thus *P* to *T* is ſuppoſed to Act in the ſame Time and Manner, when that Force is only Conſidered, as when *LM* is Join'd and United with it, which we mention as an Inſtance of the Conceivableneſs of that Doctrine, which we have Advanced of Different Forces in the ſame Space, even according to the Notions of the Philoſophy, which now obtains; Since, if a Force may be Vary'd in one Determined Point and Inſtant, it may be ſo likewiſe in a Determined Line, Surface, or Solid, which are only a Continuation of Points, or a Multiplication of Them.

The Force LM *not Accounted for.*

§. 6. MOREOVER, if the Force Expreſs'd by *PT* is that, which is Capable of Retaining the Body *P* in it's Elliptical Orbit, if there is an Addition of an Undetermined Force *LM*, and the Law of it's Acting is ſo, It will be Impoſſible to Reduce the Body *P* to any Rule of it's Revolving; ſince ſuch a Force may be ſo Great, that the Projectile may not be Able to keep it from Carrying the Body *P* to the Center *T*, or on the Contrary ſo ſmall, that it will not be ſufficient to Retain it in any Orbit, beſides that which the Force *PT* Preſcribes, and therefore will be the ſame as if there was none; and in any Intermediate Degrees, the Projectile Force and the Gravitating *LM* being only General and Abſtracted Terms, there is nothing can be Concluded from them, ſince by putting any particular Caſes, whether of the Projectile or Gravitating Force, and their Definite Proportions to each other, ſeveral Different Concluſions would Ariſe, which would be little Agreeable to the preſent Abſtracted Philoſophy, becauſe it's Reaſoning can be only true upon one Particular Proportion betwixt the Projectile and Gravitating.

The Force SM *not Accounted for.*

§. 7. AFTER the Force *LM*, we are to Conſider that of *SM*, which is the other Force into which *SL* is Reſolved, whoſe Greater Efficacy is ſaid to Conſiſt (and which is no longer Directed from *P* to *T*) in it's being Greater in Proportion to the Two Former, namely, *PT* and *LM*, where other Things are Equal, that is, as the Force of *M* to *S* is more Prevalent, it will obtain a Proportional Effect by it's Action from *P* in a Parallel Line to *ST* in Drawing the Body *P* from it's Orbit *PAB*.

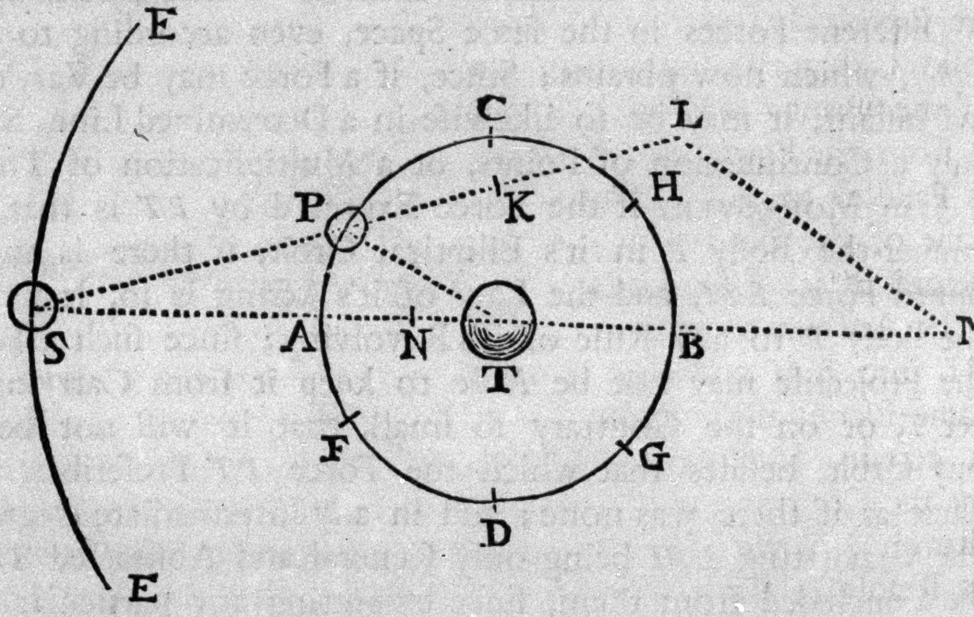
To which it may be Reply'd, FIRST, That if the Projectile Force is as Strong as that of *MS*, the Parallel Force from *P* to *TS* will be ſo far from Prevailing againſt the Forces *PT*, *LM*, that it may nearly leave the whole Province of Determining the Revolution of the Body to Them with little or no Alteration, and conſequently not Draw it from it's Orbit.

SECOND, If the Projectile Force is ſuppoſed to be Balanc'd with the Centripetal *PT*, ſo as to Deſcribe the Orbit *PAB*, It will be neceſſary to Determine their Proportions to each other, that we may be Inform'd what Degree of a Projectile Force in Conjunction with the Gravitating will Deſcribe ſuch an Orbit; For if the Projectile Force in *P* may be Different, where the Gravitating Force *PT* is the ſame, the Orbit *PAB* cannot be Deſcribed, unleſs Different Cauſes of the ſame Nature, as thoſe of the Projectile and Gravitating Force, can produce the ſame Effect; if the Projectile Force is the ſame, where the Gravitating Force is Different, as in the ſeveral Parts of an Elliptical Orbit they are ſuppoſed to be, It would not be Amiſs for this Philoſophy to ſhew us, what Proportion of the Projectile Force to the Gravitating would be ſufficient to Retain a Body from Flying off in a Tangent; for if there is not an Exact Balance betwixt the Two Forces, the one or the other will Prevail, and the Body will either ſink to the Center, or Proceed in a Right Line; if therefore an Equal Balance in the Two Forces is Neceſſary in whatever Point of the Elliptical Orbit that is ſuppoſed, in any other it will be Impoſſible to obtain; becauſe the Gravitating Force is Different, where the Projectile is the ſame.

THIRD, It is far from being Manifeſt (whatever Theories may be Contriv'd of the Reſolution of Forces, which has been ſhewn to be only a Contrivance), that a Body, which Tends from *P* to *S*, ſhould Act in any Reſpect in a Line Drawn from *P* Parallel to *TS*, unleſs a Body, which Actually Gravitates according to the Direction of *PS*, does Actually Gravitate in a Different Direction by the Power and Efficacy of the ſame Force, which Gravitates from *P* to *S*, which is Abſurd and a Contradiction, much Leſs can it Gravitate by the ſame Force from *P* to *T*, or *L* to *M*, as we have before Obſerv'd.

The Force SM *being Equal to* SN *not Accounted for.*

§. 8. ANOTHER Thing Aſſerted in this Reaſoning is, that if *SN* Repreſents the Accelerating Attraction of *T* to *S*, it will be either Equal to *SM*, or Greater, or Leſs; in the Firſt Caſe *P* and *T* will be Equally Attracted, and in the Second and Third the Difference of them will be Reſolv'd into *NM*.



As to the Firſt Suppoſition of *SN* and *SM* being Equal, ſince that will be at Equal Diſtances of *P* and *T* from *S*, it is certain, that the Attraction will not be Equal, altho' the Accelerating Forces are, but the Real Attraction will be Proportional to the Magnitude of the Bodies, where the Accelerating Forces are the ſame; and albeit this might perhaps make no Diſturbance in the Orbits, if the Revolution of each of the Bodies *P*, *T*, was only Conſider'd, becauſe the Different Sums of the Accelerating Forces might poſſibly occaſion no more Difference in the Progreſs of each Body, than Two Different Motions, whoſe Velocities were the Same, would; Yet, notwithſtanding this, where *P* and *T* are Refer'd in their Forces to a Third Body *S*, the Balances betwixt the Force of *P* and *S*, and *T* and *S*, will not be the ſame, unleſs the Two Different Sums of the Accelerating Forces are ſo, which is Impoſſible; if therefore the Sum of the Accelerating Forces in *T* is Greater than that in *P*, it will be either much more Difficult, or much more Eaſy, to Draw the One out of it's Orbit, than the Other, for the ſame Reaſon, that Two Bodies, which are Mov'd with the ſame Velocities, and whoſe Motions or Sums of Velocities are Different, will have a Different Effect, when Acted upon by the ſame Force.

NOR can there be any Thing Objected againſt what foregoes, unleſs it is Deny'd, that the Sum of the Accelerating Force in *T*, in Reſpect of *S*, is Greater than that of *P*, in Reſpect of the ſame Body, or which is all one, unleſs it is Affirm'd, that *S* has the ſame Influence upon *P* and *T*, which are ſuppos'd to be Endued with Two Different Sums of the ſame Accelerating Quality.

BESIDES which, that the Accelerating Forces in *P* and *T* are the ſame, can be no otherwiſe Prov'd or Imagin'd than upon the Suppoſition of an Homogeneous and Abſtracted Matter, the Abſurdity of which has been already ſhewn; For, if there ſhou'd be as much Difference betwixt the Matter, which Conſtitutes the Planets, as there is betwixt Earth, Water, Fire, and Æther; I believe no one will be apt to Grant their Accelerating Forces to the Center are the Same, tho' the Portions of Matter were Equal.

The Force MN *not Accounted for.*

§. 9. If therefore the Firſt Suppoſition of *SN* being Equal to *SM*, at Equal Diſtances of *P* and *T* from *S*, is not Certain, the Second of their being Unequal, and of their Difference being Reſolv'd into *NM*, will be likewiſe Unprov'd.

Let us yet Grant this, and that the Attraction *SN* is leſs than the Attraction *SM*, it is not Evident, which yet is Affirm'd, that *SN* would take off ſo much from the Attraction *SM*, as *SN* Repreſents, and conſequently, that there would only Remain the Difference of *NM*.

Because *SN*, when it Expreſſes the Force from *T* to *S*, is Different from *SN*, conſider'd as a Part of *SM*, which Explains a Force Acting from *P* Parallel to *SN*, and not Tending to the Point *S*, and therefore *SN* will not Equally Draw *P* and *T* to the Center *S*, nor will *NM* be the only Difference betwixt the Forces *SN* and *SM*, which is Aſſerted.

Again, If this were likewiſe Allow'd, namely, that *NM* was the Difference betwixt the Forces *SN* and *SM*, yet there will be a quite Contrary Reſult from *SN* being Greater than *SM*, or being Leſs than it; in the Firſt Caſe, *S* will be Drawn from it's Orbit, and in the Second, *P* will be Diſturb'd in it, whereas it is ſuppos'd, that, in both Caſes, *P* will be Affected only in it's Revolution: But this we ſhall Conſider more Particularly in the following Sections, after we have Examined into the Second Caſe of the Preſent Propoſition.

Concerning the Revolution of the Bodies in Different Planes, and the Force of MN *in that Caſe.*

§. 10. As to the Second Caſe it is now ſuppos'd, that the Leſſer Bodies *P* and *S* are Revolv'd about the Greateſt *T* in Different Planes, from whence it is ſaid to follow, that the Force *LM* by Acting according to the Line *PT*, ſituate in the Plane of the Orbit *PAB*, will have the ſame Effect, as before, nor will it Diſturb the Body *P* from the Plane of it's Orbit; whereas *MN*, by Acting according to a Line, which is Parallel to *TS*, Diſturbs the Body *P*, when that of *S* is Converſant out of the Line of the Nodes, and Induces a Variation in Reſpect of it's Latitude, as well as before in it's Longitude.

In Anſwer to which, it is Firſt to be obſerv'd, that the Reſolution of the Force *SL* into *LM* and *SM* is upon the Suppoſition of thoſe Lines being Drawn in the ſame Plane, if therefore Two Different Planes are Conſider'd, that is, which are of a certain Inclination to each other, as *PAB*, *ESE*, the Gravitation of *S* to *P*, or the Contrary, will be Different from what is Expreſs'd by *SL*, when *P* and *S* are Revolv'd in the ſame Plane, and conſequently, the Forces *LM*, *SM*, into which it is Reſolv'd; from whence it is Certain, that the Real Forces *LM*, *SM* are not the ſame in the one Caſe, as in the other, and therefore, that both *LM* and *SM* may Occaſion by their Real Forces Different Diſturbances of the Orbits, *PAB*, *ESE*, from what is here Confeſs'd.

Second, If *S* and *P* are Revolv'd in Different Planes, *MN* will either Act Parallel to *ST*, and *ST* being out of the Plane, in which *AT* lies, *TS* will be Inclin'd to that Plane, and with it Conſtitute the Angle *STA*, or elſe *MN* will Act Parallel to *AT*, in both which Caſes *MN* will fall out of the Plane, in which *STM* is in this Figure ſuppos'd to Lye, and conſequently, *LM* will in neither Caſes be in the ſame Direction with *PT*, which is Preſum'd; nor on the other Hand, will *MN* in the Firſt Caſe Attract *S* in a Parallel Line to *ST*, which is Affirm'd, and in the Second, *MN* is Imagin'd to Draw *S* Parallel to *ST*, whereas the Obvious and Real Attraction is in a Line Inclin'd to it, and Conſtituting an Angle, *STA*, with it; or, which is the ſame, *MN* is ſuppos'd to be a Right Line at the ſame Time, that *NT* or *AT* with *TM* form an Angle *NTM* or *ATM*, which is Impoſſible.

The Firſt Corollary of this Propoſition not Conſider'd, for the Reaſon Alledg'd.
Sir If. Newt. Princip. Præfat. Lib. 1.

§. 11. Having Conſider'd the Propoſition in General, we ſhall now Proceed to the Corollaries of it.

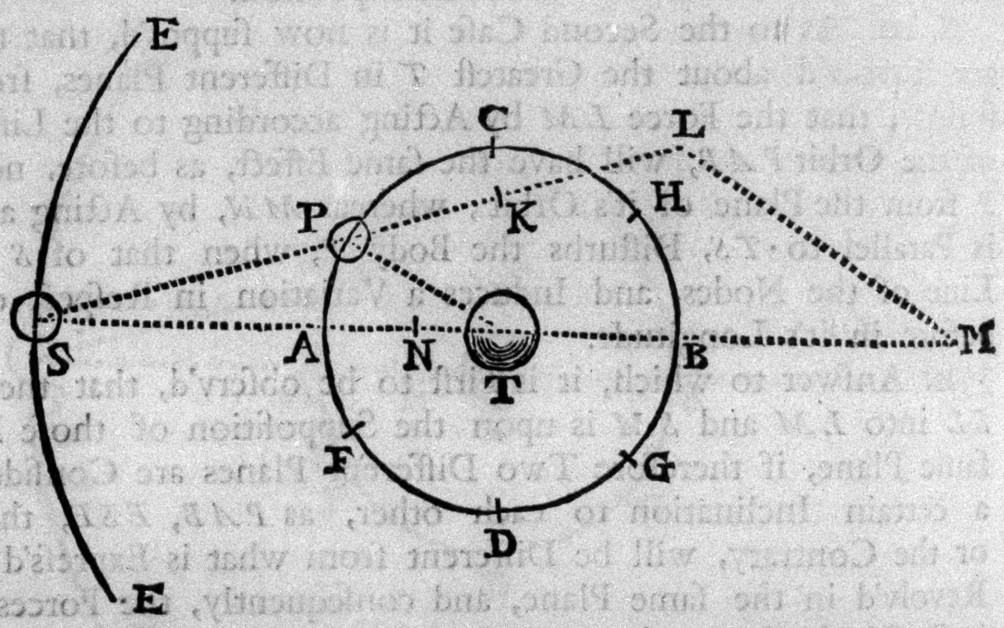
The Firſt we ſhall omit, as it Concerns more Bodies than Two Revolving about a Greater, ſince our Intention is to Confine this Inquiry to the Revolutions of the *Earth* and *Moon* about the *Sun*, in order to Explain which this Hypotheſis was principally Contriv'd, for if this is not True, neither in it's Principles nor it's Solutions, we have no Reaſon to Extend it any Farther.

The Second Corollary of this Propoſition Explain'd.
Sir Iſ. Newt. Princ. Prop. 66. Corol. 2. Lib. 1. Edit. 2. Dr. Gregory's Aſtronom. Prop. 1. §. 1. Lib. 4.

§. 12. The Second Corollary is, That in a Syſtem of Three Bodies *T*, *P*, *S*, if the Accelerating Attractions of any Two to a Third are to one another Reciprocally as the Squares of the Diſtances, the Body *P* with the Radius *PT* will Deſcribe an Area about the Body *T* with a Greater Celerity near the Conjunction *A* and the Oppoſition *B* or near the Syzygiæ, than near the Quadratures *C* and *D*; For all the Force, by which the Body *P* is Urg'd, and the Body *T* is not Urg'd, and which does not Act according to the Line *PT*, Accelerates or Retards the Deſcription of the Area, as it is Directed *in Antecedentia*, or *in Conſequentia*, and ſuch is the Force *MN*; Since This in the Paſſage of the Body *P* from *C* to *A* Tends *in Antecedentia*, and Accelerates the Motion; Then in it's Paſſage from *A* to *D* it is Directed *in Conſequentia*, and Retards it; From thence to *B* it Tends *in Antecedentia*, and again Accelerates the Motion; And laſtly, it Retards it in the Paſſage from *B* to *C in Conſequentia*.

Objections againſt the Truth of the Second Corollary.
Dr. Keill's Aſtronom. Lect. 5. Pag. 63. & 73. Edit. 1.

§. 13. As to what Reſpects the foregoing Corollary, before we Conſider it, we ſhall Examine, how this Scheme is Applicable to the Motion of the Secondary Planets about the Primary ones; ſince here Two Leſſer Bodies are Imagin'd to be Revolved about a Greater, that is, *S* and *P* about *T*, whereas *P* ſhould be Revolv'd about *S*, whilſt *S*, round which the Revolution is made, is Carry'd about *T*; But it is Prov'd in Aſtronomy, that it is the ſame Thing, whether the *Sun* and *Moon*, or *S* and *P*, are Revolv'd about the *Earth* or *T*; or whether the *Moon* is Revolv'd about the *Earth*, and both of them round the *Sun*, or *P* about *T*, and both about *S*.



Having Premis'd this, we ſhall now Inquire into the Reaſoning Alledg'd in §. 12, in which it is ſaid, that the Attraction of *MN* Accelerates *P* in it's Paſſage from *C* to *A*, that is, that the Difference betwixt the Direct Attraction of *P* to *S*, according to the Line *MS*, and the Direct Attraction of *T* to *S* Cauſes this Effect, which Difference muſt be Greater or Leſs than the Attraction of *T* to *S*, neither of which Suppoſitions will Juſtify the Preſent Reaſoning; for ſince the Accelerating Forces are ſuppos'd to be the ſame both in *P* and *T* at Equal Diſtances, or, which is the ſame, ſince the Bulk of each Body do's not come into the Computation of the Forces of them, and ſince the Diſtances from *S*, which only are Imagin'd to cauſe a Difference in their Forces, are variable from *C* to *A*, (for *P* when Situate in *C* will be at a Greater Diſtance from *S* than *T* is, and at a Leſs than it when Situate in *A*) it will follow, that, in the one Caſe or the other, *P* will not be Accelerated from *C* to *A*; Becauſe, if *C* or any Intermediate Point betwixt *C* and *A* is at a Greater Diſtance from *S* than *T* is, it is as Poſſible that *SL* ſhould fall as much below *SK* the Middle Diſtance, as it is here ſuppoſed to be Produced beyond it, and conſequently, *SM* would fall below *ST* or *SN*, which Repreſents the Attraction of *T* to *S*; which if ſo, *MN* would not Accelerate the Motion of *P* from *C* to *A*, ſince the Difference betwixt the Direct Attraction of *T* to *S*, and *P* to *S*, would be Leſs than Nothing.

On the other Hand, if *P* is Situate in *A*, or in any Intermediate Point betwixt *A* and *C*, which is at a Leſs Diſtance from *S* than *T* is, *SL* will be Extended beyond *SK* the Middle Diſtance, and *MN* will be a Difference, betwixt the Two Attractions of *P* and *T* to *S*, Greater than Nothing; But then the Queſtion will be, whether even ſuch a Difference will Accelerate the Motion of *P* from *C* to *A*; for if *MN* Acts by a Superior Force to all others, and according to the Line *MS* or a Line Parallel to it Drawn from *P*, it ſeems to be Evident, that it will be ſo far from Accelerating the Motion of *P*, that it will in Effect Retard it; Becauſe Nothing can Accelerate a Projectile or a Centripetal Motion, of which *CPA* is ſuppos'd to Conſiſt, unleſs ſuch a Force, as falls in with the one or the other, to both which, yet, *MN* is plainly Oppoſite, and neither Concurs in it's Efficacy with the Tangent of the Circle *CPA*, nor with the Radius of it; for *MN*, Acting from *P* in a Parallel Direction to *MS*, both Acts againſt *PT*, and a Tangent Drawn to *P*, that is, both againſt the Centripetal Force, and the Projectile; and in the Syzygiæ *A* and *B*, where the Acceleration ſhould be the Greateſt, *P* will be the moſt Retarded, becauſe *MN* will then Act in a Direct Oppoſition to the Centripetal *AT*, *BT*, and to the Tangents or the Projectile at *A* and *B*, where *MN* Hangs like a Weight upon the Projectile, and Cloggs and Obſtructs it's Progreſs, or elſe Propells it, in Lines Parallel to *BM*, from *D* to *B*, and by that means Preſſes upon *P*, and Endeavours to thruſt it from it's Orbit, eſpecially in the Parts towards *B*, which cannot but be an Impediment to it's Courſe thro' *DB*, ſo far from Advancing it; This is ſaid, ſuppoſing *MN* to be here Repulſive, which yet is not ſhewn, and may be juſtly Queſtion'd, and if it is not Repulſive, it has not the leaſt Pretence to Accelerate the Planet's Motion in that Portion of it's Orbit.

P is Imagin'd to be Accelerated from *C* to *A*, becauſe *P* is more Attracted to *S*, than *T* is, by the Exceſs of the Force *MN*, this Force yet is not ſuppos'd to Draw *P* farther from *T* towards *S*, ſince, if ſo, it might not ſpend it ſelf in the Acceleration of *P*, but in making it Deſcribe a Larger Orbit without any Acceleration at all; On the Contrary, it is ſuppos'd to Accelerate *P*, and to Contract it's Orbit by that Acceleration, ſo that the Syzygiæ *A* and *B* Approach nearer to *T* than the Quadratures *C* and *D*, all which is ſaid without any Proof or Demonſtration; for why *P* ſhould come nearer to *T* by Gravitating more towards *S* than it, or why *P* ſhould be Accelerated rather than Deſcribe a Larger Circuit about *T*, than it would have otherwiſe done, is Equally Inconceivable; but when we come to Prove the Repulſive Power of *MN*, by which *P* is Quickned in it's Progreſs from *D* to *B*, we are told, that *T*, Gravitating more to *S* than *P*, is Attracted more towards it by the Force *MN*, than *P* is, and conſequently, that *T* Receding from *P*, ſituate betwixt *D* and *B*, towards *S* is the ſame, as if *P* ſhould Recede from *T* with the ſame Velocity towards *M*, and therefore *MN* has here a Repulſive Force; *MN* conſequently is allow'd to have a Power of Making *T* Approach towards *S*, in order to Prove this Repulſive Force, which was not Granted before to it, in Reſpect of *P* in it's Paſſage from *C* to *A*, which it did not Draw towards *S* from it's Orbit, but only Accelerated in it, and by that means cauſed it to Recede from *S* and Approach towards *T*; and yet Preſuming all this to be True, which is no more than ſaying Things at Pleaſure, *MN*, by Driving and Impelling *T* towards *S*, would only Effect, that *P* ſhould Deſcribe *DB* at a Greater Diſtance from *T*, and in the Portion of a Larger Orbit about it, which would not Increaſe but Diminiſh it's Apparent Velocity without any Real Repulſive Force at all.

Let us now Conſider the Progreſs of *P* from *A* to *D*, which is ſaid to be Retarded, but why it ſhould be any more, than from *C* to *A* is not Evinced; For *MN*, which Acts from *P*, in every Point betwixt *A* and *D*, Parallel to *MS*, and againſt the Centripetal Force *PT* and the Projectile in every Individual Tangent to thoſe Points, will have the ſame Effect in the Progreſs of *P* from *A* to *D*, as it had from *C* to *A*; for it makes no Variation, whether *P* moves from *C* to *A*, or from *A* to *D*, whilſt the Centripetal Force *PT* is the ſame in both Caſes, and the Projectile Force in the Tangent is on both Hands Loaded with a Gravitating Force, as *MN*, which is Foreign to it, and Deſtructive of it; Thus, ſuppoſing Two Tangents, the one at *C* and the other at *D*, which is the moſt favourable Caſe, which can be put for the Preſent Philoſophy, and let the Projectile Force in the Tangent at *C* Act the ſame way with the Gravitating *MN*, and at *D* the Contrary, I ſay the Projectile Force will be Equally hindered from having it's Proper Effect in the one Caſe, as in the other; For if the Gravitating Force of *MN* in *D* is Equal to the Contrary Projectile in a Tangent Parallel to *NM*, and Acting from *N* towards *M*, the Projectile will be Deſtroy'd and not able to Proceed in a Second Tangent from *D* towards *B*; and the ſame may be ſaid of a Tangent in *C*, if the Gravitating Force *MN* is Equal to the Projectile in that Tangent, for tho' they Tend the ſame way of *M* to *N*, yet the Gravitating Force continuing ſtill the ſame, the Projectile will not be able to Proceed in a Second Tangent from *C* towards *A*, becauſe it was Clogg'd with a Weight before,

which

which Equally with the Projectile Urged it out of the Circle; and therefore it cannot Proceed in a New Tangent Inclin'd to the Former, and towards the Center *T*, and for the ſame Reaſon it will be Obſtructed in Proceeding in a Third, Fourth, or any other Tangent.

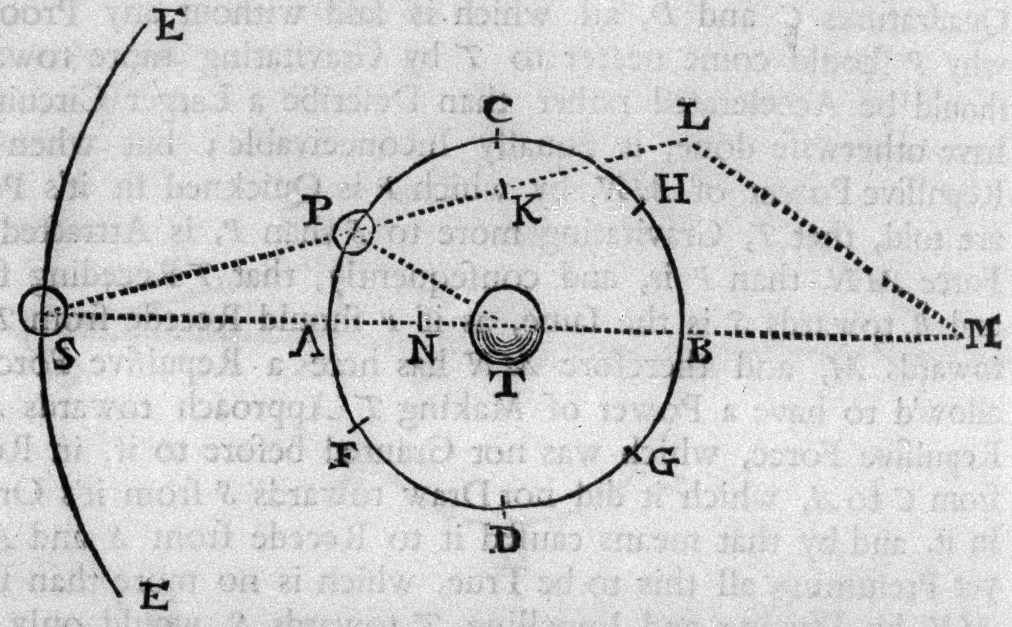
If *MN* the Gravitating Force in *C* is Greater than the Projectile in the Tangent, it will ſtill more Obſtruct the Projectile in it's Motion, and if *MN* is Leſs, it will Leſs hinder the Projectile, but not Accelerate it; And what has been ſaid in Reſpect of the Tangents and the Projectile Forces, at *C* and *D*, will obtain in Proportion in all the Points betwixt *C* and *A*, and betwixt *A* and *D*.

As to *P* being Accelerated betwixt *D* and *B*, and Retarded betwixt *B* and *C*, it is liable to all the Objections of it's Progreſs betwixt *C* and *A*, and *A* and *D*, and of *MN* being Conſidered, as a Repulſive Force in the Planet's Courſe thro' *BC*, as before thro' *DB*; All this is ſtill Argued upon the Suppoſition of a Gravitating and Projectile Force, which Forces have been already Conſidered and Shewn to be Arbitrary, as alſo upon the Suppoſition of Matter being Similar and Homogeneous in it's ſelf, which Notion likewiſe has been Refuted, and that the Diagonal Force is Reſolved into the Sides of the Parallelogram, which has not been Proved.

The Third Corollary Conſidered and Examined. Sir Iſ. Newt. Princip. Prop. 66. Coroll. 3. Lib. 1. Dr. Gregory's Aſtronom. Prop. 1. §. 1. Lib. 4.

§. 14. The next Corollary is, that by the ſame Reaſoning it is Evident, that the Body *P*, other Things being Equal, is Moved with a Greater Velocity in it's Conjunction and Oppoſition, than in it's Quadratures.

Which in the First Place is not True in this Reaſoning, however it is in Fact, unleſs the foregoing Corollary is ſo.



Second, Suppoſing the foregoing Corollary is True, it is not any more Evident, that *P* is Accelerated in it's Conjunction at *A*, from being Accelerated from *C* to *A*, than that it is Retarded there, from it's being Retarded in it's Progreſs from *A* to *D*, and the like may be ſaid concerning it's being Accelerated in it's Oppoſition at *B*; for why *CA*, in which *P* is Accelerated, rather than *AD*, in which it is Retarded, ſhould give the Denomination of *P* being Accelerated rather than Retarded in the Parts on each Side next adjoining to *A*, is as Incomprehenſible as it is Precariouſly and Arbitrarily Aſſerted in this Hypotheſis; or why *DB*, in which it is Accelerated, rather than *BC*, in which it is Retarded, ſhould give the Denomination of it's being Accelerated, rather than Retarded in the Parts adjoining to *B* in it's Oppoſition.

What farther has been Argued, in Reſpect of the Conjunction and Oppoſition of the Revolving Body, againſt it's being Accelerated, Equally obtains in it's Quadratures againſt it's being Retarded, That is, a Point, as *A* or *B* in the Syzygiæ, or *C* and *D* in the Quadratures, which lies Intermediate to an Acceleration and Retardation, can be no more ſaid to be Accelerated than Retarded, and *Vice Verſâ*.

The Fourth Corollary Explain'd and Conſidered. Sir Iſ. Newt. Princip. Prop. 66. Corol. 4. Lib. 1. Dr. Gregory's Aſtronom. Prop. 2. §. 1. Lib. 4.

§. 15. The Fourth Corollary is, That the Orbit of the Body *P*, other Things being Equal, has a Greater Curvity in the Quadratures, than in the Conjunction and Oppoſition: Becauſe Bodies, which obtain a Greater Velocity, are Leſs Deflected from a Rectilineal Progreſs, or, which is the ſame, Recede Leſs from a Right Line.

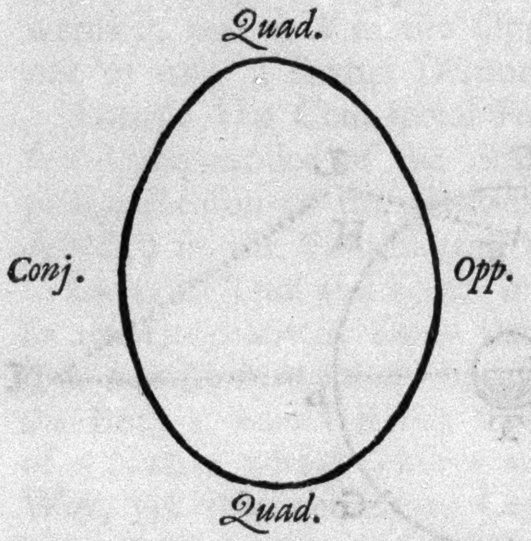
Besides, The Force *KL*, or *NM*, in the Conjunction and Oppoſition, is Contrary to the Force with which the Body *T* Attracts the Body *P*, and therefore Diminiſhes it; But the Body *P* will Recede Leſs from a Right Line, where it is Leſs Urged towards the Body *T*.

First, As to the Firſt Reaſon Alledged, it Evidently depends on the Truth of the Two preceding Corollaries, for if it cannot be Proved from them, that the Body *P* is Moved with a Greater Velocity in it's Conjunction and Oppoſition, than in it's Quadratures, it ſignifies Nothing to tell us, that Bodies, which obtain a Greater Velocity, are Leſs Deflected from a Rectilineal Progreſs.

Granting which Corollaries, it is not yet Plain, that Bodies, which obtain a Greater Velocity, are Leſs Deflected from a Rectilineal Progreſs, unleſs upon this Suppoſition, that the Greater the Force is, which Acts according to the Direction of the Tangent, the Leſs Power will the Centripetal have to Bend and Incline the Body to the Center, about which it is Revolved.

Whereas all that, which concerns a Projectile or a Tangent Force and a Centripetal, has been already Evidenced to be a Creature of the Mind, and that the Reſolution of Curves into ſuch Forces is either Diſputable or Groundleſs; Beſides which, *MN*, which is ſuppos'd to Increaſe the Velocity of the Revolving Body *P*, does not Act according to the Direction of the Tangent, and therefore cannot be Conſidered as a Force united with the Projectile, from which the Centripetal Draws and Impells the Body, which is Revolved.

Farther, If this were likewiſe Allow'd, it will follow, that, in the Conjunction and Oppoſition, where the Velocity is Swifter, the Body *P* will Approach nearer to the Center, and in it's Quadratures will Retire farther from it, ſo as to Deſcribe an Orbit Reſembling an Ellipſis, according to the Figure Annext; for in that Figure only an Orbit has it's Oppoſite Sides in one Caſe more Rectilineal, and in the other of a Greater Curvity; which is Impoſſible upon the Preſent Suppoſition, where the Projectile Force is continually Increaſing and Decreaſing, and the Centripetal Continues the ſame; ſince, if we Imagine any Determined Centripetal Force, by which the Body *P* is Attracted to the Center, and a Projectile, by whoſe Counter-Action to the Centripetal it is kept up in it's Orbit from falling to ſuch Center, if the Projectile is Increaſed, as in the Conjunction and Oppoſition, it will not make the Centripetal Force Greater, but take off and Diminiſh from it's Urgency to the Center, and conſequently, will not cauſe the Body in it's Revolution to Approach nearer to it; On the Contrary, if the Projectile Force in the Quadratures is Diminiſhed, it will not Diminiſh the Gravitating, but rather Increaſe it, by Leaving it more Entirely to it's own proper Tendency, from whence the Body will not Recede from, but Approach nearer to the Center of it's Revolution.

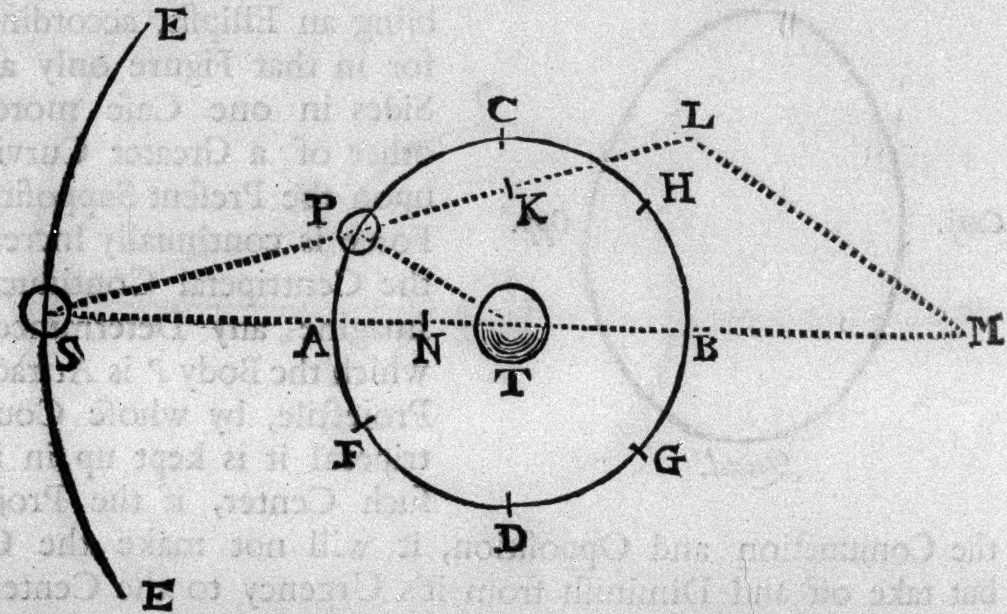


Second, As to the Second Reaſon Alledged for the Proof of this Corollary, namely, that the Force *MN*, in the Conjunction and Oppoſition, is Contrary to the Force, with which the Body *T* Attracts the Body *P*, and therefore Diminiſhes it, from whence the Body *P* will Recede Leſs from a Right Line, where it is leſs Urged towards the Body *T*: This Reaſon, we ſay, is Firſt in the General not true in an Orbit, which is ſuppoſed to be Deſcrib'd by a Gravitating, and a Tangent or Projectile Force; Becauſe where a Force, as *MN*, Acts directly Contrary to a Gravitating, yet ſince the Projectile is join'd with the Gravitating, and they are Both in an Æquilibrium, ſo that the Body *P* does neither Fall towards the Center, nor Proceed in a Tangent, it is Evident, that the Force *MN*, which Diſturbs it from that Æquilibrium, as much Obſtructs it from Going forward in a Tangent, as from Tending to the Center; and conſequently, the Body *P* will Equally Recede from a Right Line, as it does from the Center, and therefore not Leſs, where it is leſs Urged towards the Body *T*, ſince it would be Carry'd nearer to *S*, and Leave the Tangent in ſome Meaſure as well as the Center.

We add Secondly, Suppoſing the Force *MN* contrary to the Gravitating Force of *P*, if it had the Effect of making it Recede Leſs from a Right Line, that is, if it Reſign'd to the Projectile a Greater Force, it would at the ſame Time at leaſt make the Gravitating Leſs, and therefore, that Part of the Orbit, which Recedes Leſs from a Right Line, ſhould Recede more from the Center, whereas the Contrary is Affirm'd in this Hypotheſis of Forces, to wit, that in the Conjunction and Oppoſition *P* Approaches nearer to the Center, and in the Quadratures is farther Retired from it.

Third, If *MN* Acts directly Contrary in the Conjunction and Oppoſition to the Gravitating Force of *P* to *T*, That is either meant in the Points *A* and *B* only, or elſe in all the Intermediate Points betwixt *C* and *A* in Conjunction, and betwixt *D* and *B* in Oppoſition; if the Firſt, it will ſignify nothing to the Rectilineal Progreſs of the Body *P* betwixt *C* and *A*, or *D* and *B*, ſince this Reaſon obtains only in the Points *A* and *B*; if the Second, it will not be eaſily Conceived, how *MN* Acts Contrary to the Gravitating Force from *P* to *T*, unleſs in an Oblique Direction, which if Allow'd of, it does likewiſe to all the ſeveral Tangents, or the Projectile Forces of the Points in *CA*, or *DB*, and conſequently does not Accelerate the Velocity of *P*, but Retards it, as was before Obſerved.

Lastly, If all was Granted, which has been Diſputed, ſince the Accelerations are ſuppoſed betwixt *C* and *A*, *D* and *B*, and the Retardations betwixt *A* and *D*, *B* and *C*, it would follow, that the Greater Curvity of the Orbit would not be in the Quadratures, but in thoſe Parts of it, which lie betwixt the Conjunctions or Oppoſitions, and the Quadratures, that is, from *A* to *D*, and *B* to *C*; and the more Rectilineal Progreſſes of *P* would not be in the Conjunctions and Oppoſitions, but in the Parts lying betwixt the Quadratures and Them, that is, from *C* to *A*, and *D* to *B*.



The Fifth Corollary Explained. Sir Iſ. Newt. Princip. Corol. 5. Prop. 66. Dr. Gregory's Aſtronom. Prop. 2. Lib. 4.

§. 16. The Fifth Corollary is, that the Body *P*, other Things being Equal, will Recede farther from the Body *T* in the Quadratures, than in the Conjunction and Oppoſition, which has been already Conſider'd and Depends upon the former Corollaries.

The Sixth Corollary Explained and Examined. Sir Iſ. Newt. Princip. Corol. 6. Prop. 66. Dr. Gregory's Aſtronom. Prop. 3, 4, &c. Lib. 4. & Corol. Prop. 7. Lib. 4.

§. 17. The Sixth Corollary is, That ſince the Centripetal Force of the Central Body *T*, by which the Body *P* is Retained in it's Orbit, is Increaſed in the Quadratures by the Addition of the Force *LM*, and Diminiſhed in the Conjunction and Oppoſition, or in the Syzygiæ, by the Ablation of the Force *KL*, and by Reaſon of the Greatneſs of *KL* is more Diminiſhed than Increaſed, and ſince that Centripetal Force is (by *Corol.* 2. *Prop.* 4.) in a Reaſon Compounded of the Simple Reaſon of the Radius *TP* Directly, and of a Duplicate Reaſon of the Periodical Time Inverſely, it is Manifeſt, that this Compound Reaſon is Diminiſhed by the Action of the Force *KL*, and conſequently, the Periodical Time, if the Radius of the Orbit *TP* Continues the ſame, is Increas'd, and that in a Dimidiate Reaſon, in which that Centripetal Force is Diminiſhed, if the ſame Radius therefore is Increas'd or Diminiſh'd, it is likewiſe Manifeſt, that the Periodical Time is more Increaſed or leſs Diminiſhed than in the Seſquiplicate Reaſon of the ſaid Radius (by *Corol.* 6. *Prop.* 4.) If that Force of the Central Body ſhould gradually Languiſh and Decreaſe, the Body *P*, being leſs and leſs Attracted, would perpetually Recede farther from the Center *T*, and on the Contrary, if that Force ſhould be Increas'd, it would Approach nearer to it; Therefore, if the Action of the Remote Body *S*, by which that Force is Diminiſhed, be Increas'd and Diminiſhed by Turns, the Radius *TP* will be alſo Increaſed and Diminiſhed by Turns, and the Periodical Time will be Increaſed and Diminiſhed in a Reaſon Compounded of the Seſquiplicate Reaſon of the Radius and the Dimidiate Reaſon, in which that Centripetal Force of the Central Body *T* is Diminiſhed or Increaſed by the Increaſe or Diminution of the Action of the Remote Body *S*.

IN Anſwer to which, it is FIRST to be Conſidered, that the Centripetal Force of the Body *T* does not Retain the Body *P* in it's Orbit, becauſe there is a Projectile one Equally Requir'd by this Philoſophy, and becauſe it is not farther Prov'd, by what foregoes, that the Earth or Planets, for which the Preſent Hypotheſis is Contrived, are Retained in their Orbits by a Centripetal Force even in Conjunction with a Projectile, but poſſibly may be ſo by an Expanſive one of the Sun.

SECOND, Allowing this, the Centripetal Force of the Body *T* is not Increas'd by the Addition of *LM* in the Quadratures, and Diminiſh'd by the Ablation of *KL* in the Syzygiæ, unleſs upon the Suppoſition, that *SL* is Reſolved into the Forces, *LM*, *SM*, which has been before Conſider'd and Diſproved.

GRANTING which, as *SK* is ſuppoſed to Repreſent the Attraction of the Middle Diſtance, *KL*, when it falls in with the Line *SM*, will, if any Thing, in the Conjunction at *A* Diminiſh the Centripetal Force of the Body *T*, becauſe the Force Tends from *L* to *K*, and therefore Draws *A* from *T* towards *S*; and on the Contrary, in the Oppoſition at *B*, *LK* will Diminiſh the Centripetal Force of the Body *T*, by Impelling the Body *P* Leſs from *B* towards *T*, than *T* towards *S*, but then the Effects will be very Different, ſince the ſame Force *LK* Acts upon *P* in the Firſt Caſe and *T* in the Laſt, which are Bodies of a very Different Magnitude; Whereas it is Affirm'd in this Philoſophy, that the Effects are Equal and Alike by an Ablation of the Force *LK* in the Syzygiæ: Beſides, that *LK* in the Conjunction at *A* Acts by Attraction towards *S*, and at *B* in the Oppoſition by a Repulſion from it, is not ſo Evident as not to want a farther Demonſtration.

THIRD, The Centripetal Force is not Proved by *Corol.* 2. *Prop.* 4, to be in a Reaſon Compounded of the Simple Reaſon of the Radius *TP* Directly and of a Duplicate Reaſon of the Periodical Time Inverſely, as is Evident from what has been Alledg'd in the Examination of that Propoſition and the Corollaries of it.

LASTLY, Tho' the Force of the Central Body ſhould, upon it's Increaſe from *LM* in the Quadratures, Draw the Body *P* nearer to *T* by Acting more ſtrongly upon it, it is not Evident, that, upon a Diminution of that Force by *KL* in the Syzygiæ, the Body *P* would Retire farther from *T*, where the Body *P* is ſuppoſed to Conſiſt of a Nature wholly Paſſive and Unactive; for tho' an Action ſhould Impell it one Way, yet upon the entire Ceaſing of that Action, it would not be Impell'd another, but would remain Quieſcent in Reſpect of that Action, and much Leſs upon the Diminution of an Action, by which it is Impell'd one Way, would it be Impell'd, or Move a Contrary.

NOR conſequently, if the Action of the Remote Body *S*, by which the Central Force is Diminiſhed, ſhould be Increaſed and Diminiſhed by Turns, will the Radius *TP* be likewiſe Increaſed and Diminiſhed by Turns; for if by the Action of *S* the Action of *T* ſhould be ſo far Diminiſhed, as to be in an Equal Balance with it, that is, that by their Contranitent Forces they ſhould Deſtroy each others Effects towards their own Centers, the Body *P* would not lengthen it's Radius *TP* and Retire towards *S*, but would be perfectly Quieſcent in Reſpect of both theſe Forces; if therefore the Action of *T* is only ſo far Diminiſhed, as not to be Entirely Deſtroyed, it will ſtill be more Impoſſible for *TP* to lengthen it's Radius, or for *P* to be Impell'd a Contrary way to *T*, nor is it neceſſary it ſhould be ſhortned, only it would then obey the Projectile, and be carry'd Round *T* at the Diſtance *PT*; And if the Action from *P* to *T* is not only Deſtroy'd, but ſurmounted by the Superior one of *S*, *P* will Retire towards *S* and *TP* will be Produced, but then *T* will have loſt it's Influence, and the Body *P* will no longer be Revolved about the Center *T*, but Round that of *S*.

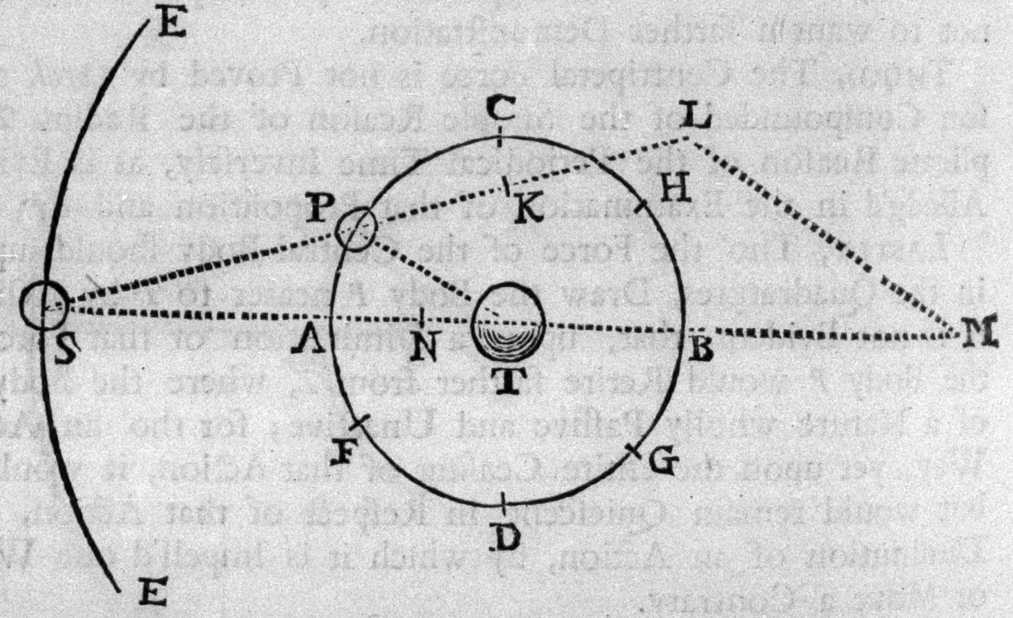
BUT that, which is ſtill more Unaccountable, is, that *LM* is ſuppoſed to fall in with *PT*, or the Centripetal Force, and to Increaſe it in the Quadratures, and *KL* to Act Counter to it, and therefore to Diminiſh it in the Syzygiæ, from whence, according to this Doctrine, it ſhould follow, that the Radius *PT* is Diminiſhed in the Firſt Caſe, and Increaſed in the Laſt; whereas we are before told, that the Radius *PT* is Longer in the Firſt Caſe, and Shorter in the Laſt, that is, Longer in the Quadratures, where there is ſaid to be a Greater Curvity of the Orbit, and Shorter in the Syzygiæ, where there is ſaid to be a Leſs.

WHAT therefore is Reaſoned concerning the Periodical Times being Increaſed or Diminiſhed upon theſe Preſumptions, which are Falſe and Groundleſs, muſt be Equally ſo.

The Seventh Corollary Explained and Examined.
Sir Iſ. Newt. Princip. Prop. 66. Corol. 7. Lib. 1.
Dr. Gregory's Aſtronom. Prop. 8, 9, 10. Lib. 4.

§. 18. THE Seventh Corollary is, That, from what foregoes, it is Conſequent, that the Axis or the Line of the Apſides of an Ellipſis, Deſcrib'd by the Body P, as to it's Angular Motion, makes it's Progreſs and Regreſs by Turns, but yet it's Progreſſes are Greater, and by that Exceſs of the Progreſſion, in each Revolution of the Body, it is Carry'd *in Conſequentia*.

FOR the Force, by which the Body P is Urged towards the Body T in the Quadratures, where the Force MN Vaniſhes, is Compounded of the Force LM, and of the Centripetal Force, by which the Body T Attracts the Body P; The Former Force LM, if the Diſtance PT be Increaſed, is Increas'd almoſt in the ſame Reaſon with this Diſtance, and the Latter Decreaſes in that Duplicate Reaſon, and conſequently, the Sum of theſe Forces Decreaſes in leſs than a Duplicate Reaſon of the Diſtance PT, and upon that Account, by *Corol.* 1. *Prop.* 45, Cauſes the Aux or the Upper Apſis to Return; On the Contrary, in the Conjunction and Oppoſition the Force, by which the Body P is Urg'd towards the Body T, is the Difference betwixt the Force, by which the Body T Attracts the Body P, and the Force KL, and that Difference, becauſe the Force KL is nearly Increas'd in a Reaſon of the Diſtance PT, Decreaſes in a Greater than a Duplicate Reaſon of that Diſtance, and therefore, by *Corol.* 1. *Prop.* 45, Cauſes the Aux or the Upper Apſis to Proceed; In the Places, which lie Intermediate to the Syzygiæ and Quadratures, the Motion of the Aux Depends jointly upon both theſe Cauſes, ſo that as the one or the other Prevails, it Proceeds or Returns; from whence it follows, that, ſince the Force of KL in the Syzygiæ is almoſt doubly Greater than the Force LM in the Quadratures, the Exceſs in the whole Revolution will be on the Side of KL, and will carry the Aux in each Revolution *in Conſequentia*.



To which it may be Firſt Reply'd, that in the Quadratures MN is ſuppoſed to Vaniſh, becauſe then the Body P is in a Middle Diſtance from S, which has been before Conſidered; Granting which, LM is Imagined to unite in it's Action with PT, upon the Reſolution of the Force SL into LM, MS, which likewiſe has been already Examin'd.

AND yet FIRST, Allowing both, it is not Proved, that LM, upon the Increaſe of PT, is Increaſed almoſt in the ſame Reaſon, becauſe, ſuppoſing PS and KS not much Different, which will be, when P is not far from the Tranſverſe or Conjugate Axis of it's Orbit, LM will be to PT, as LS to PS, and if PT is Lengthened or Increaſed, LM will be to PT in the ſame Proportion of LS to PS, which will be as the Square of the Middle Diſtance KS to the Square of the Diſtance PS, and therefore LM, will not be Increas'd almoſt in Proportion as PT is, but in Proportion as the Squares of KS and PS.

SECOND, It is not moreover Certain, if the Diſtance PT is Increas'd, that the Centripetal Force is Diminiſhed in a Duplicate Reaſon of ſuch Diſtance, according to what has been before Alledg'd, and therefore *Corol.* 1. *Prop.* 45, is Cited to no purpoſe, ſince by that the Aux or Uppermoſt Apſis is Proved to Return upon the Conceſſion, that the Sum of theſe Forces is Diminiſhed in Leſs than a Duplicate Proportion of the Diſtance PT, which is not Affirmed or Evinced, if the one Force is not Increas'd nearly as the Radius is, and the other Diminiſhed in a Duplicate Reaſon of ſuch Increaſe of the Radius. Not to add, that the Propoſition and the Corollary here Refer'd to are both of them Argued upon ſuch a Confuſ'd and Precarious Reaſoning, and upon ſo many Preſumptions of the Truth of Fluxions, and other Principles of this Philoſophy, that it would not be hard to Conteſt almoſt every Part of each; and which Propoſition we ſhall afterwards Examine.

It may be Secondly Reply'd on the other Hand, that, in the Conjunction and Oppoſition, the Force, by which the Body P is Urged towards the Body T, is not the Difference betwixt the Force, by which the Body T Attracts the Body P, and the Force KL; for KL in the Conjunction Acts in P from A to S, and therefore the Force, by which the Body P is Urged towards T, is ſuppoſed to be Diminiſh'd ſo far by that Contrary Attraction, whereas, according to what has been before Proved, if the Attraction from A to S, and A to T were Equal, A would not therefore Retire from T or to S, where the Difference betwixt ſuch Forces is Equal to Nothing, that is, if the Projectile is not Conſider'd, for that indeed in ſuch a Caſe would carry the Body in a Tangent from A, and there would be no Radius PT at all, and conſequently, if KL is Leſs than the Attractive Force of P to T, there may be an Actual Tendency of P to T at the Diſtance PT, without a Diminution of it, if KL is Greater, P will be Drawn from A towards S, and will have no Tendency to T, and therefore cannot be Retained in an Orbit by it; ſo that in the Firſt and Laſt Caſe there will be no Radius PT, and therefore no Revolution of the Aux or the Upper Apſis, and in the Second, ſince PT will continue the ſame, no Progreſſion or Regreſſion of it; If the Projectile Force is Conſidered, and is Equal to the Centripetal, in the Firſt Caſe, it will Direct the Body P in a Tangent, as was before ſaid; in the Second, it will ſurmount the Centripetal, and will likewiſe promote it in a Tangent, tho' with a Leſs Force, unleſs the Projectile is Diminiſhed in Proportion to the Centripetal, and then, as was mentioned before, PT will be the ſame in it's Revolution without any Progreſs or Regreſs of the Apſis; and in the Laſt Caſe, P will be Revolved round S, if KL is Greater than PT and the Difference Equal to the Projectile, if Leſs and the Projectile Greater, P will go off in a Tangent; And the ſame may be ſaid in the Oppoſition of P at B, with this Additional Objection, that it is not Certain, that KL Acts in a Contrary Direction to the Centripetal Force, when P is in it's Oppoſition at B, according to what has been before Conſidered, in Relation to the Action of MN.

Bbsides which, it is not Evident, that ſuch a Difference, if it were Granted, would Decreaſe in a Greater than a Duplicate Reaſon of the Diſtance PT, becauſe it is not Proved, that the Force KL is nearly Increas'd in a Reaſon of that Diſtance.

Lastly, If yet the Difference was Allowed to Decreaſe in a Greater than a Duplicate Reaſon of the Diſtance PT, it is not Certain, that the Propoſition and the Corollary Refer'd to are true, for the Reaſons above-mentioned.

The Eighth Corollary Explained and Examined.
Sir Iſ. Newt. Princip. Corol. 8. Prop. 66.
Dr. Gregory's Aſtronom. Prop. 11. Lib. 4.

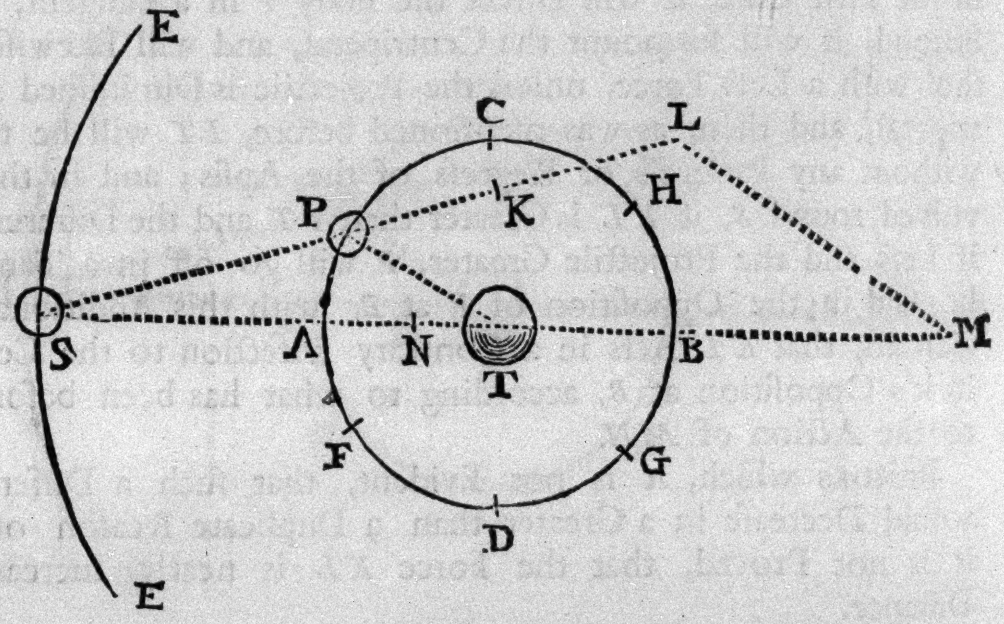
§. 19. The Eighth Corollary is, That ſince the Progreſs and Regreſs of the Apſides Depends upon the Decreaſe of the Centripetal Force, made in a Greater or Leſs than a Duplicate Reaſon of the Diſtance TP, in the Body's Paſſage from the Lower Apſis to the Upper, as alſo upon the like Increaſe in it's Return to the Lower, and conſequently, ſince this Progreſs and Regreſs is the Greateſt, where the Proportion of the Force in the Upper Apſis to the Force in the Lower Apſis Recedes the moſt from a Reciprocal Duplicate Reaſon of the Diſtances, It is manifeſt, that the Apſides in their Syzygiæ, by the Force KL or $NM-LM$ being Subſtracted, will Proceed Swifter, and in their Quadratures will Recede Slower, by the Addition of the Force LM.

But Firſt it muſt be Anſwer'd, that the Progreſs and Regreſs of the Apſides does not Depend upon the Decreaſe of the Centripetal Force, made in a Greater or Leſs than a Duplicate Reaſon of the Diſtance TP, in the Body's Paſſage from the Lower Apſis to the Upper, and upon a like Increaſe in it's Return to the Lower, Unleſs the Former Corollary is True, which we have ſhewn is not Certain, or rather that it is in Fact falſe; Beſides which, we ſhall Secondly add, that in General it is an Inconceivable Notion, that an Increaſe or Diminution of the Centripetal Force, according to a certain Proportion, ſhould be a Cauſe of the Progreſs or Regreſs of the Body P, or of it's Swifter or Slower Progreſs or Regreſs; ſince, if the Force from P to T is Diminiſhed, which before was Equal to the Projectile, ſo far as to Retain

Body *P* in it's Orbit, the Projectile will Direct it in a Tangent, when once it becomes Superior to the Centripetal, and on the Contrary, if the Force from *P* to *T* is Increas'd, it will be Superior to the Projectile, and conſequently will not be Retained in an Orbit, but will Tend to the Center; and therefore we may very juſtly Diſmiſs this Account of the Progreſſes and Regreſſes of the Apſides, as at the Beſt Precarious and Groundleſs, nevertheleſs at the End of theſe Corollaries we ſhall make a Particular Examination into the Fundamental Propoſitions of this Doctrine, That is, in our following Chapter.

The Ninth Corollary Explained and Examined. Sir Iſ. Newt. Princip. Prop. 66. Corol. 9. Dr. Gregory's Aſtronom. Prop. 12, 13. Lib. 4.

§. 20. THE Ninth Corollary is, That if any Body ſhould be Revolved about a Center in an Ellipſis by a Force, that was Reciprocally Proportional to the Square of it's Diſtance from ſuch a Center, and preſently after, in it's Deſcent from the Upper Apſis or Aux to the Lower, that Force ſhould by the perpetual Acceſs of a New one be Increas'd in more than a Duplicate Reaſon of the Diſtance Diminiſhed, it is manifeſt, that the Body by the Perpetual Acceſs of that New Force, being continually Impelled to the Center, would more Verge or Incline to that Center, than if it was Urged by the Force only Increaſing in a Duplicate Reaſon of the Diſtance Diminiſhed, and therefore would Deſcribe an Orbit Interior to the Elliptical, and in the Lower Apſis would Approach nearer to the Center than before, from whence the Orbit, by the Acceſs of this New Force, will become more Excentrical; If now the Force, in the Receſs of the Body from the Lower Apſis to the Upper, ſhould Decreaſe by the ſame Degrees as it Increaſed before, the Body would Return to the Former Diſtance, and therefore, if the Force ſhould Decreaſe in a Greater Reaſon, the Body being now Leſs Attracted will Aſcend to a Greater Diſtance, and ſo the Excentricity of the Orbit will be ſtill more Increas'd; Therefore, if the Reaſon of the Increment and Decrement of the Centripetal Force be Increas'd in each Revolution, The Excentricity will be Increaſed; and on the Contrary, the ſame Excentricity will be Diminiſh'd, if that Reaſon Decreaſes.



THUS in the Syſtem of the Bodies *T*, *P*, *S*, when the Apſides of the Orbit *PAB* are in the Quadratures, that Reaſon of the Increment and Decrement is the Leaſt, and the Greateſt, when they are in the Syzygiæ; If the Apſides are placed in the Quadratures, the Reaſon near the Apſides is Leſs and near the Syzygiæ Greater than a Duplicate one of the Diſtances, and from that Greater Reaſon Ariſes the Swifteſt Motion of the Aux; But if the Reaſon of the whole Increment and Decrement in the Progreſs betwixt the Apſides be Conſidered, it is Leſs than a Duplicate one of the Diſtances; The Force in the Lower Apſis is to the Force in the Upper Apſis in Leſs than a Duplicate Reaſon of the Diſtance of the Upper Apſis from the Umbilicus of the Ellipſis to the Diſtance of the Lower Apſis from the ſame Umbilicus; and on the Contrary, when the Apſides are placed in the Syzygiæ, The Force in the Lower Apſis is to the Force in the Upper in a Greater than a Duplicate Reaſon of the Diſtances; For the Forces *LM*, added in the Quadratures to the Forces of the Body *T*, Compound together Forces, which are in a Leſs Reaſon, and the Forces *KL* Subſtracted in the Syzygiæ from the Forces of the Body *T* leave Forces, which are in a Greater Reaſon; The Reaſon therefore of the whole Decrement and Increment in the Paſſage betwixt the Apſides is the Leaſt in the Quadratures, and the Greateſt in the Syzygiæ, and conſequently, in the Paſſage of the Apſides from the Quadratures to the Syzygiæ, it is continually Increaſed, and Increaſes the Excentricity of the Ellipſis, and in the Paſſage from the Syzygiæ to the Quadratures, it is continually Diminiſhed, and Diminiſhes the Excentricity.

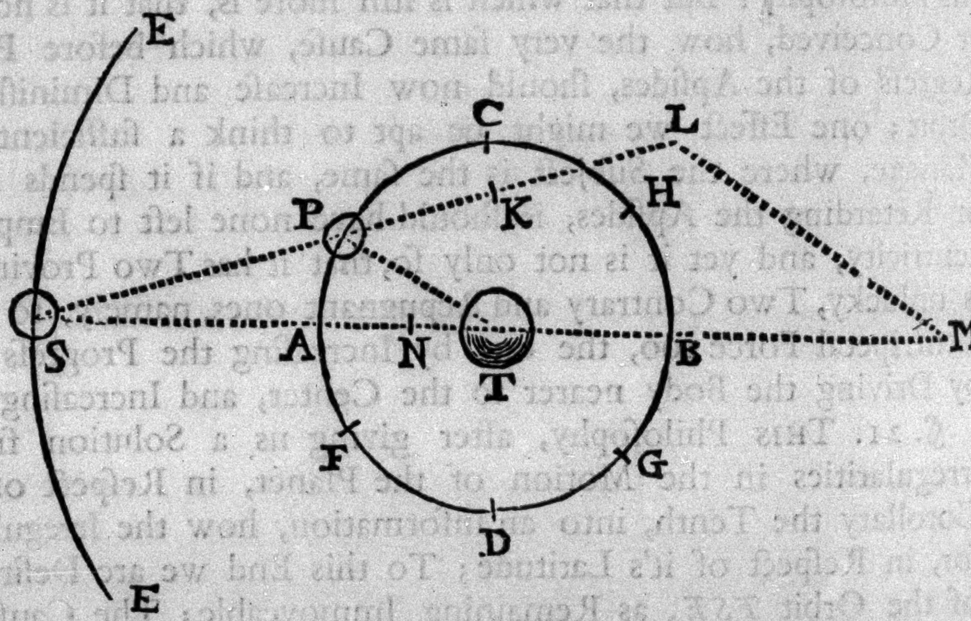
In Anſwer to which we ſay, that if the Body is more Attracted in it's Deſcent from the Upper Apſis to the Lower than in a Duplicate Reaſon of it's Diſtance Diminiſhed, by which in Conjunction with the Projectile it was before Retained in it's Orbit, the Centripetal being now Superior to the Projectile, and having overcome it ſo far, as by it's Exceſs to Draw the Body nearer to the Center in the Lower Apſis, it does not ſeem Reaſonable to allow the Projectile any farther Power to Raiſe the Body to a Greater Diſtance from the Center, for if one Force has once been actually Superior to another, how that ſhould Revive and be Reſtored to it again, which was Loſt, unleſs by the Will and Pleaſure of the Philoſopher, will not be ſo eaſily Imagin'd; for to ſay the Projectile Force continues to Puſh and Protrude the Body from the Center, notwithſtanding it is Surmounted by the Centripetal, is to affirm it to be an Innate, and therefore a Reviviſcent Force, when the Centripetal is taken off, which perfectly contradicts the Notion which this Philoſophy has of Matter, that it is perfectly Paſſive, and continues and perſeveres in a certain State of Motion or Reſt, till it is Diſturbed out of it; But here it ſeems, when a Body is Diſturbed out of it's Projectile Motion by a Superior Centripetal, when that Superiority of Centripetal Force is taken off, it can Re-aſſume it's Projectile without any new Impreſſion; which, what is it elſe but to Affirm, that the Projectile is an Innate Force in it, when yet all ſuch Innate Forces are actually Diſclaim'd by this Philoſophy? But that which is ſtill more is, that it is no ways to be Apprehended or Conceived, how the very ſame Cauſe, which before Produced the Progreſs and Regreſs of the Apſides, ſhould now Increaſe and Diminiſh the Excentricity of the Orbit; one Effect we might be apt to think a ſufficient Task for one Cauſe to Manage, where the Subject is the ſame, and if it ſpends it's Force in Accelerating or Retarding the Apſides, it ſhould have none left to Employ in Changeing the Excentricity, and yet it is not only ſo, that it has Two Provinces Aſſign'd it, but, which is unlucky, Two Contrary and Repugnant ones, namely, to Increaſe the Projectile and Centripetal Force too, the one by Increaſing the Progreſs of the Apſides, the other by Driving the Body nearer to the Center, and Increaſing the Excentricity.

The Tenth Corollary Explained and Examined. Sir Iſ. Newt. Princ. Prop. 66. Corol. 10. Dr. Gregory's Aſtronom. Prop. 15. Lib. 4.

§. 21. This Philoſophy, after giving us a Solution from it's Principles of the Irregularities in the Motion of the Planet, in Reſpect of it's Longitude, leads us, Corollary the Tenth, into an Information, how the Irregularities may be Accounted for, in Reſpect of it's Latitude; To this End we are Deſired to Conceive the Plane of the Orbit *TSE*, as Remaining Immoveable; The Cauſes of any Irregularities or Errors, as before Explained, are *NM*, *LM*; The Force *ML*, by Acting always according to the Plane of the Orbit *PAB*, will never Diſturb the Motion, in Reſpect of Latitude, nor yet the Force *NM*, where the Nodes are in the Syzygiæ, becauſe it Acts according to the Plane of the ſame Orbit, but when the Nodes are in the Quadratures, it chiefly Diſturbs them, and by continually Drawing *P* from the Plane of it's Orbit, it Diminiſhes the Inclination of the Plane in the Paſſage of the Body from the Quadratures to the Syzygiæ, and again Increaſes the ſame in the Paſſage from the Syzygiæ to the Quadratures, from whence it comes to paſs, that, whilſt the Body is in the Syzygiæ, the Inclination of the Plane is the Leaſt, and Returns to it's Former Magnitude nearly, when the Body Arrives at the next or ſucceeding Node; But, if the Nodes are placed in the Octants after the Quadratures, that is, betwixt *C* and *A*, and *D* and *B*, it will be found from what has been already Explained, that, in the Paſſage of the Body *P* from either of the Nodes to the 90th Degree, the Inclination of the Plane is perpetually Diminiſhed, afterwards in the Paſſage thro' the next 45 Degrees, ſo far as to the next Quadrature, the Inclination is Increas'd, and then thro' the next 45 Degrees to the ſucceeding Node it is Diminiſhed; The Inclination therefore is more Diminiſhed than Increaſed, and for that Reaſon is always Leſs in the Subſequent Node, than in the Preceding; And by the ſame Reaſoning, the Inclination is more Increas'd than Diminiſhed, where the Nodes are in the other Octants, betwixt *A* and *D*, *B* and *C*; Therefore the Inclination, where the Nodes are in the Syzygiæ, is the Greateſt of all: In the Paſſage of the Nodes from the Syzygiæ to the Quadratures, in each of the Appulſes or Arrivals of the Body to the Nodes, the Inclination is Diminiſhed, and becomes the Leaſt of all, when the Nodes are

are in the Quadratures, and the Body in the Syzygiæ; afterwards it Increaſes by the ſame Degrees, by which it before Decreas'd, and, when the Nodes Arrive at the next Syzygiæ, the Inclination Returns to it's firſt Magnitude.

In Anſwer to which, First, it is not Proved, That, when the Nodes are in the Syzygiæ, the Forces, *LM*, *MN*, do not Diſturb the Motion of the Body *P*, in Reſpect of Latitude, if they do, when the Nodes are placed in the Quadratures; that is, let *EST*, or *ETE*, be an Immoveable Plane, and let *AB* be the Line of the Syzygiæ, whilſt the Plane *ACB* is Elevated above the Plane *ETE*, and *ADB* Depreſſed below it, it is ſaid, that *LM*, *MN* cannot make any Diſturbance in the Orbit, altho' it is Acknowledged they may, when *CD* is the Line of the Nodes, and *CBD*, *CAD*, the Planes, are the one Depreſs'd below, and the other Elevated above the Immoveable Plane *ETE*, which ſeems to be Impoſſible; for *MN* muſt as much Draw *P* towards *S*, in ſome oblique Poſition or other, from *C* or *D*, which are not in the ſame Plane with *AB* the Line of the Nodes, as *MN* will Draw *P* from *A* or *B* towards *S* in ſome oblique Poſition or other, where the Line of the Nodes is *CD*, and conſequently, not in the ſame Plane with *A* or *B*; That is, ſuppoſing *EST* or *ETE* to be the Immoveable Plane, when the Nodes are in the Syzygiæ, *D* and *C* will be the one Depreſſed below, and the other Elevated above it, and when they are in the Quadratures, *B* and *A* will be ſo, and therefore in both Caſes, there will be a Diſturbance from the Force *MN*, or elſe in neither; for if *MN* Acts Parallel to *TS*, or the Plane *ETE*, which it is ſuppoſed to do, it will Attract *P* in *C*, as well as in *A*, when Raiſed above it, to a Point nearer to that Plane, than it would by it's own Force have otherwiſe Deſcribed.



Second, When the Nodes are in the Syzygiæ, that is, when *C* is Raiſed above the Plane *ETE*, without a Compariſon of them to what they are in the Quadratures, it is not Certain, that the Force *MN* has thoſe Effects, which are ſuppoſed, of Acting both by an Exceſs and a Defect upon the Body *P*, according to what has been before Argued, that is, by way of Attraction and Repulſion.

Third, The Reſolution of the Force *SL* into *LM*, *MS*, is likewiſe not Proved, as we have already ſhewn.

Fourth, The Accelerating of the Body *P*, by the Force *MN*, from *C* to *A* is Inconſiſtent with it's Inclining the Plane *BCA* towards *ETE*, ſince the one Draws it according to the Orbit, and the other Draws it down from it.

On the other Hand, when the Nodes are in the Quadratures *C*, *D*, there are the following Objections againſt the foregoing Account.

First, That *MN* cannot, by continually Drawing the Body *P* from the Plane of it's Orbit, Diminiſh the Inclination of the Plane in the Paſſage of the Body from the Quadratures to the Syzygiæ, and again Increaſe the ſame in the Paſſage of it from the Syzygiæ to the Quadratures; Becauſe, ſuppoſing *CAD*, where the Nodes are *C* and *D*, to be Raiſed above the Immoveable Plane *ETE*, or Depreſs'd below it, for the Caſe is the ſame; The firſt Queſtion will be, when the Body *P* is in *C* or *A*, if the Force *MN* has an Effect to Draw it towards the Plane *ETE*, how the Body *P* will ever Riſe from that Plane, in it's Paſſage from *A* to *D*; For if the Force *MN* is Increas'd in it's Progreſs from *C* to *A*, it is not ſhewn, why it ſhould not as gradually Draw the Body *P* to the Immoveable Plane, and conſequently keep it continually ſo Inclin'd, as it is at *A*; for, tho' *MN* ſhould be Gradually Diminiſh'd from *A* to *D*, it would not be Conſequent, that *P* ſhould Raiſe it ſelf from the Plane *ETE*, unleſs it was

Endued with ſome Innate Force, which ſhould thus Aſſiſt it's Elevation, which is not Acknowledged.

Second, If this could be done, it is not Evident, as was ſaid before, how *MN* ſhould Accelerate *P* in it's Paſſage from *C* to *A*, which is Affirmed, and yet Perform the other Province of Drawing it down from it's Orbit, which Attraction from it's Orbit muſt Retard it's Motion.

Third, It is not ſhewn, how *CAD*, conſidered as belonging to a Secondary Planet, is the Part of an Orbit Inclined to *ETE*, unleſs by ſuppoſing, that *P* Deſcribes an Orbit Inclined to it, which, in Reſpect of the Earth's Orbit about the Sun in Particular, the Moon for Inſtance moſt certainly does; But why it ſhould do it, is far from being Explain'd by this Philoſophy, which Preſumes and Suppoſes the Inclination of the Orbit, and then makes an Arbitrary uſe of the Force *MN* to Draw the Body *P* out of that Orbit; whereas, if the original Inclination of the Orbit of the Secondary Planet to the Primary was not Suppoſed, all the other Reaſonings upon it would be of no Importance; If it is Suppoſed and not Accounted for from any Principles in this Philoſophy, it's Deviations from it's own Orbit may be as well Suppoſed and as juſtly Accounted for from ſuch a Suppoſition, as it's Grand Deviation from the Orbit of it's Primary Planet is by a mere Suppoſition only.

Fourth, Since *MN* Acts according to the Plane *ETE*, or in a Direction Parallel to it, and not in any oblique one from *A* to *S*, when the Body *P* is in *A*, it cannot Diminiſh the Angle of Inclination, tho' it is there Imagined to have the Greateſt Effect, the Angle of Inclination being there the Leaſt; becauſe *P*, when in *A*, Gravitates to *S* in a Line Parallel to *TS*, and conſequently, the Force *MN* will only Draw *P* from it's Orbit at an Equal Diſtance from *TS*, and therefore will not more Incline *TA* or *TP* to it, than if there was no ſuch Attraction; for tho' it muſt be Confeſſed, that if *P* at *A* is Drawn out of it's Orbit, in a Parallel Direction to *TS*, to any Point next *A* towards *S*, if a Line is Drawn from *T* to ſuch a Point, it will have a Leſs Inclination to *TS*, than *TA* has, yet when *P* is in ſuch a Point, if it is Attracted to *T* in a Parallel Direction to *TA*, which there is as much Reaſon for, as that it ſhould be Attracted to *S* in a Parallel Direction to *TS*, the Angle of Inclination of *PT* to *TS*, will be the ſame in both Caſes; for beſides, if *P* in *A* is Drawn into another Plane, the Center ſhould be Removed into the ſame Plane, otherwiſe there could be no Revolution, according to *Prop.* 1. of this *Philoſophy*, which ſuppoſes an Immoveable Plane neceſſary to the Revolution, and therefore if *P* Shifts from one Plane to another, when the Center is the ſame, the Foundation of all the Preſent Reaſoning is Deſtroyed.

Fifth, The Reſolution of the Force *SL* into *LM*, *MS*, as before, is Unproved, and whatever has been alledged in Affirmation of theſe Principles.

Sixth, In the Paſſage of *P* from *A* to *D* all the Arguments are the ſame againſt the Plane of the Orbit *CAD* Increaſing in it's Inclination to *ETE*, which were us'd againſt it's being Diminiſh'd in the Paſſage of the Body from *C* to *A*.

As to the other Progreſſes of the Body from *D* to *B*, and *B* to *C*, it is not neceſſary to conſider them, unleſs upon this Account, that there is one Objection, which lies againſt them in Particular, namely, that it is not certain, that a Defect of the Force *MN* will have the ſame Effects, as the Exceſs of it.

There will be therefore nothing more to ſay on this Head, Excepting, that when the Nodes are Placed in the Octants, or in any other Poſition, The Reaſoning, with ſome Circumſtantial Allowances, will be the ſame.

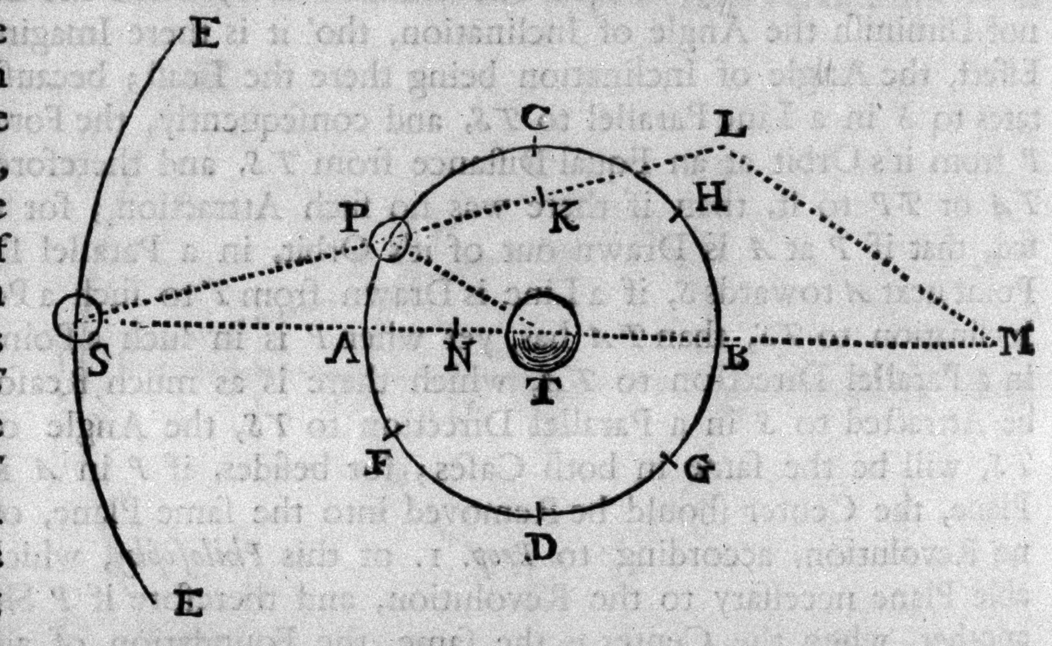
§. 22. The Eleventh Corollary is, That, ſince the Body *P*, when the Nodes are in the Quadratures, is continually Drawn from the Plane of it's Orbit, and that towards the Part *S* in it's Paſſage from the Node *C*, thro' the Conjunction *A*, to the Node *D*, and to the contrary Part, in it's Paſſage from the Node *D*, thro' the Oppoſition *B*, to the Node *C*, it is Evident, that, in it's Motion from the Node *C*, the Body Perpetually Recedes from the Plane of it's Orbit, till it comes to the Next Node, and conſequently, in this Laſt Node paſſes at a Greater Diſtance from the Firſt Plane *CD*, thro' the Immoveable one *ETE*, that is, not in the other Node *D* of that Plane, but in a Point, which Verges or Inclines from thence towards the Body *S*, and therefore is a New Place of the Node Tending Backwards, that is rather towards *A* than *B* in Reſpect of *D*; and by a like way of Reaſoning, the Nodes will

The Eleventh Corollary Explained and Examined.
Sir Iſ. Newt. Princip. Prop. 66. Corol. 11.
Dr. Gregory's Aſtronom. Prop. 14. Lib. 4.

Recede from the Places they obtained before, in the Paſſage of the Body from *D* to *C*; and therefore the Nodes, when Situate in the Quadratures, have a Continual Regreſs, but when in the Syzygiæ, where the Motion of *P* Receives no Diſturbance in Reſpect of it's Latitude, the Nodes are Quieſcent; and in the Intermediate Places, they Share in both theſe Influences, and by Conſequence, being either Actually carry'd Backwards, or being Actually Stationary in each Revolution, they find a Regreſſion, or are carry'd *in Antecedentia*.

But in the First Place, we muſt be Allow'd to obſerve, that this Corollary Depends upon the Former, ſince, if the Body *P* is not Drawn from it's Orbit in the ſame Method, which this Philoſophy Preſcribes, as, by what is before Proved, it is not, there can be no Argument from thence for the Regreſſion of the Nodes.

Second, Tho' that were Granted, namely, that *P* was Drawn from it's Orbit in it's Paſſage from *C* to *D*, it would not follow, that there ſhould be a Regreſſion of the Nodes; Becauſe *MN* would only produce this Effect at the moſt, to wit, that *P*, ſuppoſing the Nodes in the Quadratures, would be Attracted to a Plane below *CAD*, and which would have a Leſs Inclination to the Plane *ETE*, that is, *CAD* would Vibrate upon the Axis *CD*, and conſequently there would be no Regreſſion of the Nodes in the ſame Plane, but they would be Quieſcent, and only the Inclination of *CAD* to *ETE* would be Diminiſhed and Increaſed by Turns.



Third, This is the more Confirm'd, becauſe it is Inconceiveable, when the Nodes are in the Quadratures *C* and *D*, that they ſhould Recede from thoſe Points, if *CAD* is conſidered as a Plane Inclined to *ETE*; ſince *P*, when it is in *C* or in *D*, muſt have the ſame Attraction to *S* from the Force *MN*, and therefore, if the Node is in *C*, notwithſtanding the Attraction of *MN*, it muſt be likewiſe in *D*, notwithſtanding ſuch Attraction; If yet the Node *D* is Attracted by *MN* to a Point on this Side *D* towards *A* or *S*, in like Manner *C* ought to be, from whence the Line of the Nodes will not be carry'd in a Revolution *in Antecedentia*, but Parallel to *CD* towards *A* or *S*.

Fourth, If the Plane *CAD* Interſects the Plane *ETE* on this Side *D*, it's Inclination to *ETE* will be in a Greater Angle, and therefore Increas'd by the Force *MN*, whereas by the Preceding Corollary it was Diminiſhed by the ſame Force, which is a Contradiction.

Sir Iſ. Newt. Prop. 66. Corol. 12.

Fifth, All the Objections, which lie againſt the Preceding Corollaries and this Propoſition, are Equally certain here; As to the Twelfth Corollary, which is, that all the Errors, Deſcrib'd in theſe Corollaries, are ſomething Greater in the Conjunction of the Bodies *P* and *S*, than in their Oppoſition upon Account of their Greater Generating Forces *NM* and *LM*, we ſhall omit the Examination of it, as Depending on the Former, and Proceed to the Thirteenth.

The Thirteenth Corollary Explained and Examined. Sir Iſ. Newt. Princip. Prop. 66. Corol. 13.

§. 23. The Thirteenth Corollary is, That ſince the Reaſons of theſe Corollaries do not Depend upon the Magnitude of the Body *S*, all, which has been ſaid before, Obtains, where the Magnitude of the Body *S* is Determined or Suppoſed to be ſuch, that the Syſtem of the Two Bodies *T* and *P* may be Revolved round it; and from the Increaſe of the Body *S*, and conſequently of it's Centripetal Force, from which the Errors of the Body *P* do Ariſe, all thoſe Errors will become (in Equal Diſtances) Greater in this Caſe than in the other, where the Body *S* is Revolved about the Syſtem of the Two Bodies *P* and *T*.

In Reply to which it muſt be First ſaid, that nothing of what foregoes is True, and therefore, that which is here Alledged cannot be, ſo far as it is a Conſequence of it.

Second, This is only an Accommodation of the Preſent Scheme to the Revolution of the *Earth* and *Moon* about the *Sun*, and for that Reaſon does not concern the Argument we are now Conſidering, Namely, the Merits and Truth of the Preſent Hypotheſis in General; tho' it may be ſaid, that by the Increaſe of the Body *S*, and it's Centripetal Force, ſomething more than an Increaſe of the foregoing Errors may be Produced, whilſt the Projectile Forces Continue the ſame, namely, the Attraction or Detruſion and Compreſſion of the whole Syſtem of *P* and *T* to the Center *S*.

As to what Reſpects the 14th, 15th, 16th, and 17th Corollaries, it will not, after what has been ſaid, be neceſſary to Enter into a Diſquiſition of them, ſince they chiefly Relate to a Calculation of theſe Errors and Irregularities in the Primary and Secondary Planets, but if ſuch Irregularities are not juſtly Accounted for, it will be as Certain, that their Quantities and Proportions are not.

The Eighteenth and Nineteenth Corollaries Explained and Examined. Sir Iſ. Newt. Princip, Prop. 66. Corol. 18, 19.

§. 24. The Eighteenth Corollary is an Application of this Doctrine to the Flux and Reflux of the Sea, in order to ſolve which, it is ſuppoſed, that ſeveral Fluid Bodies are Moved round the Body *T*, at Equal Diſtances from it, with the ſame Laws and Conditions, with which the Body *P* is Revolved about the ſame Body *T*, Afterwards from theſe Fluid Bodies becoming Contiguous a Fluid Ring is Conceiv'd to be form'd Round and Concentrical to the Body *T*; If ſo, the ſeveral Parts of the Ring, by performing all their Motions according to the Laws of the Body *P*, will Approach nearer to the Body *T*, and will be moved Swifter in the Conjunction and Oppoſition of them and the Body *S*, than in the Quadratures; and the Nodes of this Ring, or it's Interſections with the Plane of the Orbit of the Body *S* or *T*, will be Quieſcent in the Syzygiæ, but out of the Syzygiæ they will be Moved *in Antecedentia*, or which is the ſame, will have a Regreſſion, and this Regreſſion will be the Swifteſt in the Quadratures, and Slower in the other Intermediate Places; The Inclination of the Ring will be alſo Vary'd, and it's Axis will Oſcillate in each of the Revolutions, and when the whole Revolution is Performed, it will Return to it's former Situation, unleſs ſo far as it is Carry'd Round by the Preceſſion of the Nodes.

After this, it is, in Corollary the Nineteenth, ſuppoſed, that the Globe of the Body *T*, which conſiſts of a Matter which is not Fluid, is Enlarged and Extended to this Ring, and in a Channel, which is Excavated thro' it's Circuit, contains the Water, and is uniformly Revolved with the ſame Periodical Motion about it's Axis; This Liquid being Accelerated and Retarded by Turns, as in the foregoing Lemma, will be Swifter in the Syzygiæ and Slower in the Quadratures than the Superficies of the Globe, and conſequently will have a Flux and Reflux in the Channel after the ſame Manner as the Sea has; The Water by Revolving about the Quieſcent Center of the Globe, if the Attraction *S* is taken away, will acquire no Motion of a Flux and Reflux, and the ſame Reaſoning Obtains in a Globe, which Proceeds uniformly *in Directum*, and in the mean Time Revolves about it's own Center, by the 5th *Corol.* of the Laws, as alſo in a Globe, which is uniformly Drawn from it's Rectilineal Courſe, by the 6th *Corol.* of the Laws, but let the Body *S* Approach, and the Water will be immediately Diſturbed by it's Unequal Attraction, for the Attraction of the Water which is Nearer will be Greater, and of that which is Remoter Leſs; But the Force *LM* will Draw the Water Down in the Quadratures, and will make it Deſcend to the Syzygiæ, and the Force *KL* will Draw it upwards in the Syzygiæ, and will ſtop the Deſcent of it, and make it to Aſcend as far as the Quadratures.

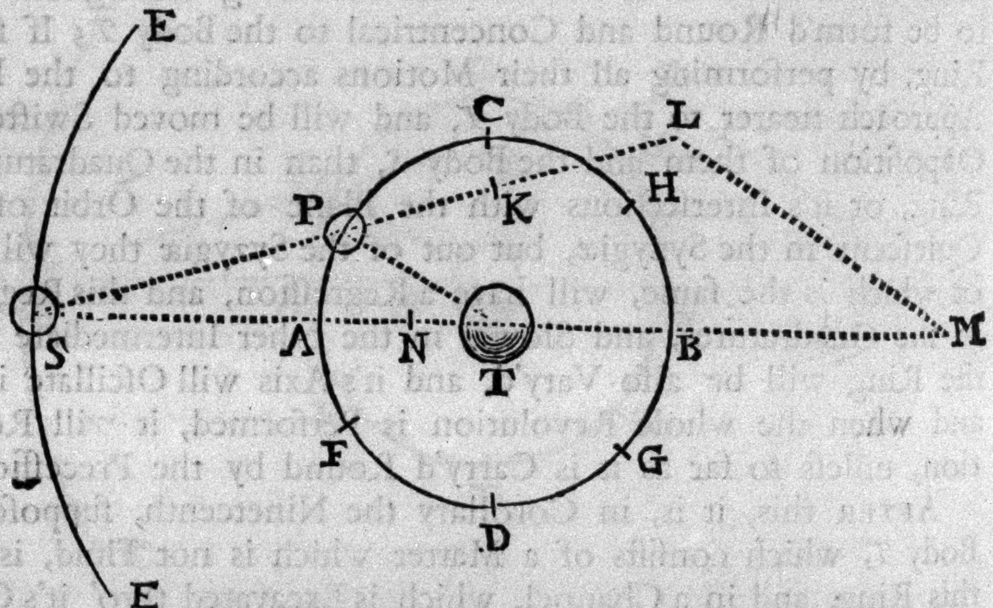
This Account of the Flux and Reflux of the Sea ſo evidently Depends on the Laws of Motion in the Revolution of a Secondary Planet about a Primary, that there will be no Occaſion very Particularly to conſider it, after a Confutation of thoſe Laws.

We ſhall only First ſay, That if all thoſe ſuppoſed Laws of Revolution were True, it is not very Conceiveable, how they are Applicable to the Ocean, unleſs it made ſuch a Ring in it's Channel about the *Earth*, and was Inclin'd in the ſame Manner to the Plane *ETE*, as the Orbit of the *Moon* is, neither of which Things are in Fact true, that we know of.

Sir Iſ. Newt. Princ. Lib. 3. Prop. 6. Corol. 1, 2.

Second, If this were ſo, ſince Water in this Philoſophy is ſuppoſed to be of the ſame Homogeneous Matter with any other Solid Matter, and only Differs in it's Quantity, which is Proportional to it's Weight, and not in it's Real Nature and Conſtitution, ſeeing, in it's Revolution about the Center *T*, one Kind of Matter, as Water, is Diſturb'd, there is no Reaſon Given, nor can be, why another ſhould not, as Earth, or even the whole Surface of the Globe it's ſelf, if it had the ſame Inclination with this Imaginary Ring of Water, unleſs that it in Fact is not.

Third, Let this be Granted, yet the Action of *S* would not obtain the Effects Propoſed, for it could only Diſturb every Parcel of the Fluid Ring, as it Paſſed, according to the Laws Obſerved in the Revolution of *P*; the Conſequence of which would be, that in the Paſſage of any Part of the Fluid Ring from the Quadratures to the Syzygiæ, there would be a Quicker Motion, which would again Flag and Languiſh in it's Paſſage from the Syzygiæ to the Quadratures, in Caſe each Fluid Part preſerved it's Situation, and what Acceleration any Part acquired in it's Paſſage from *C* to *A*, or Retardation from *A* to *D*, would be ſtill Increas'd by the Succeeding Revolutions; From whence would Reſult nothing of a Flux or Reflux, as is Pretended and Imagined, but a Puſhing or Protruding forwards of the ſame Fluid Ring, according to the Velocities Impreſs'd from *C* to *A*, and the Retardations of them from *A* to *D*; If the Parts of the Fluid Ring do not preſerve the ſame Situation in ſucceeding one another, but the preceding Parts, as betwixt *C* and *A*, which are mov'd Swifter, are heaped and thrown upon thoſe which are mov'd Slower, as betwixt *A* and *D*, All the Conſequence will be, that they will now move Slower from *A* to *D*, than before betwixt *C* and *A*; from whence it will follow, in either Caſes, that the Parts of the Fluid Ring will proceed Swifter betwixt *C* and *A*, and Slower betwixt *A* and *D* without any Imaginable Reflux, which we can at preſent Apprehend, that is, that the Waves, by the Accelerating and Retarding Action of the Moon, will ſtill ſucceed one another in a Swifter or a Slower Motion, without any Reflux or Regreſſion of Them.



Fourth, And as to the Waves of the Fluid Ring being Raiſed or Elevated in the Quadratures, and Depreſs'd in the Syzygiæ, it will be ſtill Leſs to the purpoſe of Accounting for a Flux and Reflux of them, in this way of Raiſing and Depreſſing them, tho' poſſibly Another, which we have already Explained, may be the only one to ſolve this Difficulty; However, ſince the Preſent Elevation and Depreſſion of the Waters is Aſcribed to the Celerity or Slowneſs of their Motion in the Syzygiæ and Quadratures, and ſince that can have no ſuch Effect, namely, to Elevate or Depreſs them, as has been Proved in the Preceding Article, and before in the Examination of that Corollary, which Reſpects the Enlargement of the Orbit of *P* in the one Caſe and the Depreſſion of it in the other, ſuch an Explication can be of no Force or Significance.

Book 1. Chap. 5.

Fifth, Since the Water is Swifter in the Syzygiæ and Slower in the Quadratures, it ſhould be more Depreſſed in the Syzygiæ, and more Prominent and Convex in the Quadratures, whereas the Contrary is here Affirmed, That it is more Elevated in the Syzygiæ, and more Depreſſed in the Quadratures; 'Tis true, the Forces *LM* in the Quadratures, and *KL* in the Syzygiæ are called in to Remedy this Defect; But is it not ſomething Strange, that the Two Acceſſory Forces, *LM* and *KL*, ſhould be able to Effect more than the Main and Principal Force *MN*, by which this whole Machine is Acted? And it is Evident, that *MN*, according to this Philoſophy, would Accelerate the Waters in the Syzygiæ, and Retard them in the Quadratures, and by Conſequence, Depreſs them in the one Caſe and Raiſe them in the other, in Contradiction to Fact and Experience.

SIXTH, 'Tis true LM in the Quadratures Drives the Waters towards the Center by Acting from P to T, and KL in the Syzygiæ Draws them from it, and both Aſſiſt to the Elevation of the Waters in the Syzygiæ, and the Depreſſion of them in the Quadratures, and if we ſuppoſe farther MN not to Accelerate the Waters in the Syzygiæ, but to Draw and Attract them from the Center, which Effect it is ſaid likewiſe to have, MN would alſo Contribute to the Production of the ſame Phænomenon; but here lies an Objection againſt this Account, that tho' MN, KL, may be eaſily Imagined to be Attractive of the Waters in the Conjunction A, and conſequently to Raiſe them, yet how the ſame Forces ſhould be Repulſive of them in the Oppoſition B, is not nor can be Explained, as we have before ſhewn in the Examination of that Corollary.

SEVENTH, The Fluid Ring it ſelf, as was before Intimated, is an Imaginary Buſineſs, and cannot be Juſtified from any Thing which we find in Nature; for how is the Ocean like ſuch a Fluid Ring, which Spreads it ſelf like one Vaſt Pond, Broken and Interrupted with Various Continents of Land, and has no more the Reſemblance of a Fluid Circulating in one continued Courſe about the Center of the Earth, than of any Thing elſe to which it is the moſt unlike: We ſhall not therefore conſider this Account of the Flux and Reflux of the Sea any farther, tho' there are ſeveral other Difficulties, which lie againſt it, nor yet the Doctrine of the Planets, as it is Compared with what is Obſerved in their Revolutions, albeit we might there likewiſe ſhew, that there are as many Adjuſtments of Calculation and Suppoſitions made to Effect, that the Appearances of Nature ſhould anſwer theſe Hypotheſes in Reaſoning, as we have ſhewn that there are Adjuſtments of Reaſoning, and Suppoſitions made to Anſwer theſe Appearances, and particularly in the Theory of the Moon, ſo much Celebrated in the preſent Philoſophy. But our Deſign being only to Inquire into the *Principles* of *Philoſophy*, we ſhall not at preſent trouble our ſelves to Examine, how they agree with what is propoſed to be ſolv'd by them, ſince, if the Principles are Falſe, it is Impoſſible the Solutions ſhould be True; Thus in the Magnet, if the *Striate Particles* of *Des-Cartes* are a Romance and a Ludicrous Fiction, as all will acknowledge them to be, who know any Thing in theſe Studies, tho' they ſhould be pretty well Adapted to the Solution of ſeveral Phænomenons in that Body, no one of Senſe would yet take them to be any thing Real or Exiſting in Nature.

Concluſion of this Chapter. Dr. Gregory's Aſtronom. Prop. 35. Lib. 1.

§. 25. FROM an Examination into the Principles, by which the Irregularities of the Planets are Explained, we might Proceed to the Doctrine of Comets, as to the Orbits of which it is not fully Determined, whether they are more truly Repreſented by a Parabola, an Hyperbola, or an Ellipſis, and all that is Proved, or Endeavour'd to be Proved, is, that a Comet is Moved in ſome Conick Section or another, in one of whoſe Umbilicus's is the Sun; The Parabola is rather choſen, but without any certain Proofs of it's being the Trajectory of the Comet. In Truth and Reality, if the Orbits of the Planets are not regularly and truly Adjuſted by this Philoſophy, the Extravagant Deviations of the Comets from ſuch Rules of Motion or Acting muſt be Leſs Accounted for. It will not therefore be neceſſary to Inquire into the Orbits, which the Comets Deſcribe, ſince the Cauſes Aſſign'd of ſuch Revolutions are Precarious or Falſe, all that will be Expedient to do, if any Thing, is to know upon what Reaſons the Caudæ or Tails of them are Explained, nor will this be neceſſary, ſince they do not Proceed upon any Mathematick Principles, but upon the Gueſſes and Conjectures of Men, which are Various according to Dr. *Gregory*, *Prop.* 4. *Lib.* 5, and which perhaps we may find ſome other Time to Examine. We ſhall therefore Conclude theſe Corollaries with an Admiration, that thoſe Philoſophers, who pretend that their Reaſon, not their Religion, is the only Diſtinction of Men from Brutes, ſhould fall into Notions, which have no Reaſon to ſupport them, that they ſhould Run themſelves into all the Follies and Abſurdities Imaginable, as is Evident, when they come to be Examined by Common Senſe, and at the ſame Time Think to ſecure themſelves in all theſe, by Drawing of Lines, and Circles, and Angles about them, as a Kind of Fortification and Defence for ſuch Errors.

CHAP. VI.

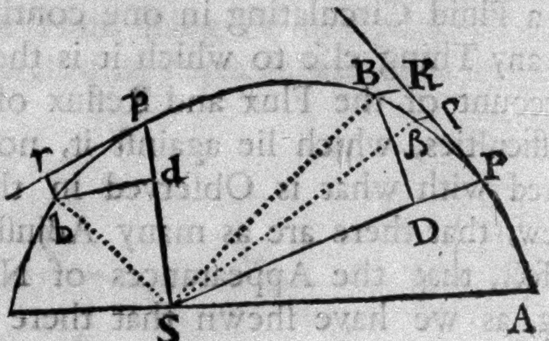
Concerning thoſe Propoſitions, which Relate to the particular Forces, by which the Planets are Retained in their Orbits.

The Remaining Propoſitions in the Phyſical Aſtronomy Explained and Examined.

§. 1. WE have in the Two foregoing Chapters Examined into ſeveral Propoſitions Relating to the Phyſical Aſtronomy, but in the Ninth and Tenth Corollaries of the Former Chapter, where the Apſides and the Excentricity of the Orbits were Conſidered, we were Obliged to take ſome Things for Granted, which were not there Proved, and which we Promiſed to ſubmit to a farther Inquiry, which when we have done, there will be ſcarcely any Thing Remaining, which will Require our Labour or Trouble in theſe Matters.

The Firſt Propoſition Explained. Sir Iſ. Newt. Princip. Prop. 6. §. 2. Lib. 1. Dr. Gregory's Aſtronom. Prop. 37. Lib. 1.

§. 2. THE Firſt Propoſition, which we ſhall take Notice of is, that if a Body is Projected according to the Direction of any Right Line, and at the ſame Time is Urged by a Centripetal Force Tending to the Center S, ſo that, by a Motion Compounded of theſe Two, it ſhould Deſcribe the Curve APp, to which in any Point P, let PR be a Tangent, and from the Point B, which is the next to P, let BD be Drawn Perpendicular to the Right Line SP, and BR Parallel to it, and let there be the like Conſtruction made at any other Point of the Curve, as p; It is Affirmed in this Propoſition, that the Centripetal Force in P is to that in p, as $\frac{Spq \times bdq}{br}$ to $\frac{SPq \times BDq}{BR}$, or, that the Centripetal Force in P is Reciprocally, as $\frac{SPq \times BDq}{BR}$, where $PRBD$ is Indefinitely Small.



FOR, Let the Force in P, which Tends towards the Center S, be called V, Let the Time in which the leaſt Arc PB is Performed, or in which the Body by it's *Vis Inſita* alone would Deſcribe the leaſt Tangent PR, be called T, Let the Centripetal Force, Acting from the Point p, be called v, and Let the Time, in which pb is Performed, or in which the Tangent pr would be Deſcribed, be called t; Let alſo the Arc $P\beta$ be Taken, which the Body Deſcribes in the ſame Time, in which it Deſcribes the Arc pb, and Let $\beta\rho$ be Drawn Parallel to PS; Theſe Things being ſuppoſed, the Reaſon of the Small Line BR to that of br is Compounded of the Reaſon of BR to $\beta\rho$, and of the Reaſon of $\beta\rho$ to br, or $\frac{BR}{br} = \frac{BR \times \beta\rho}{\beta\rho \times br}$, but, by Lemma 11th of the Method of Naſcents and Evaneſcents, BR is to $\beta\rho$ as PBq to $P\beta q$; and theſe Arcs PB, $P\beta$, ſince they are the Leaſt or the Evaneſcent ones, are as the Triangles of an Equal Height BSP, βSP, that is, by *Prop.* 1*ſt*, and 2*d*. of this Philoſophy, as the Times, in which they are Deſcribed by a Radius Drawn to S, or by the Preſent Conſtruction, as the Times, in which the Arcs PB, pb are Deſcribed; Again the Small Line $\beta\rho$ is to that of br as the Cauſes, which Produce them, that is, as the Centripetal Force in P to that in p, and therefore the Reaſon of the Small Line BR to that of br, is Compounded of the Duplicate Reaſon of the Times, in which PB, pb, are Deſcribed, and of the Reaſon of the Centripetal Force in P to that in p, that is, $\frac{BR}{br} = \frac{T^2}{t^2} \times \frac{V}{v}$, and therefore $\frac{V}{v} = \frac{BR \times t^2}{br \times T^2}$; But by *Prop.* 1, of this Philoſophy T is to t as the Area SBP is to the Area Sbp, or as the Double of the Former $SP \times BD$ is to the Double of the Latter $Sp \times bd$; If therefore in the Place of the Reaſon $\frac{t^2}{T^2}$ we ſubſtitute $\frac{Spq \times bdq}{SPq \times BDq}$, $\frac{V}{v}$ will be $= \frac{BR \times Spq \times bdq}{br \times SPq \times BDq}$, that is, by Dividing both by $BR\times br$, $V.v::\frac{Spq\times bdq}{br}.\frac{SPq\times BDq}{BR}$; and therefore the Centripetal Force in P to S is Reciprocally, as the Solid $\frac{SPq\times BDq}{BR}$. *Q.E.D.*

The Vis Inſita *or the Projectile Force and the Gravitating Precarious and Uncertain.*

§. 3. In Anſwer to which, we muſt obſerve, Firſt, That the Body is ſuppoſed to be Projected in the Tangents PR and pr, or to Proceed by it's *Vis Inſita* in thoſe Tangents, which Projection or *Vis Inſita* is wholly Undefined and Undetermined in this Figure, whether it is Conſtant or Mutable, and what Proportion it bears to the Centripetal Force, which Tends towards S; It is only ſaid, in General and at Large, to be ſuch, as, in Conjunction with that Force, will Deſcribe the Curve APp. We have given our Objections againſt the Projectile Force, or *Vis Inſita*, and the Gravitating Force or Centripetal already, which need not be here Repeated, upon the Truth of which, yet, all this Reaſoning ſtands; the Propoſitions here quoted for the Support of this Demonſtration have been alſo Examined and Refuted, and we ſhall only ſay farther, that, if the Planets are Revolved round the Sun by it's Expanſive Force Carry'd about it's Axis by a Perpetual Gyration, this whole Doctrine of Projectile and Centripetal Forces will fall to the Ground; and that they are thus Revolved, there are ſome Arguments to make us Believe it, and none, which can perhaps in Fact Diſprove it, and therefore this Imaginary Deſcription of Curves is Falſe or Uncertain, and far from being Mathematically Evinced or an Indiſputable Propoſition of Geometry.

The ſeveral other Suppoſitions in this Demonſtration Examined.

§. 4. Again, In the Second Place, if this *Vis Inſita* or Projectile Force is no more than ſuch, which, with the Centripetal Force here particulary Defined and Expreſſed, is capable of Deſcribing the Curve APp, this is only Telling us, that we may adjuſt Matters ſo betwixt the Projectile and Centripetal Force, that the Latter ſhall have the Proportion which we Aſſign it, tho' we do not Prove, that the Projectile will comply with thoſe Conditions, which we are pleaſed to Preſcribe to it; Thus $\frac{BR}{br}=\frac{T^2}{t^2}\times\frac{V}{v}$, from which Equation this Propoſition is Concluded.

That is, First, Suppoſing, that PR the Tangent is or would be Deſcribed by the *Vis Inſita* alone in the ſame Time T, as the Arc PB is by the Projectile and Centripetal Force together, that is, Suppoſing, that the Force PB conſiſts of the Forces PR and RB, and that the Diagonal Force is Reſolvible into the Lateral ones, a Doctrine, which has been before Conſidered and Objected to; Beſides which, the Diagonal here is a Curve, which was there ſuppoſed to be a Right Line, and we have ſhewn, that tho' a Curve is Infinitely Diminiſhed, it cannot put on that Form.

Second, By Aſſuming the Arc $P\beta$, which the Body is to Deſcribe in the ſame Time, as it Deſcribes the Arc pb, and by making the ſaid Aſſumed Arc Leſs than PB, it is ſuppoſed, that PB is not the Leaſt Arc, which yet was before ſuppoſed to be the Leaſt Arc, and therefore in Order to bring this Demonſtration to it's Concluſion, Two contrary Suppoſitions are Introduced, that PB is the Leaſt Arc, and that it is not the Leaſt Arc, which cannot but be a very Convincing Way of Geometrick Reaſoning.

Third, By Aſſuming the Arc $P\beta$ Leſs than the Arc PB, it is ſuppoſed, that the Time, in which the Arc $P\beta$ or pb is Deſcribed, is Leſs than the Time in which the Arc PB is Deſcribed, as Pp is Leſs than PR; for if the Time was Equal or Greater, Pp would be Equal to or Greater than PR, which would not ſuit with this Demonſtration; if therefore pb is an Arc Equal to PB, and is Deſcribed in a Leſs Time than PB is, it is Deſcribed with a Greater Velocity, and conſequently, if $P\beta$ is Deſcribed with the ſame Velocity as PB, the Time Pp will be Leſs to make it Anſwerable to the Arc pb, which it Repreſents; and from hence it is, in part, Infer'd, that $\frac{BR}{br}$ is $=\frac{T^2}{t^2}\times\frac{V}{v}$, that is, by, in part, ſuppoſing it. For it is not Proved, that T or the Time of PR is Greater than t or the Time of pr = to the Time of Pp, or that the Velocity in pb is Greater than the Velocity in PB, Imagining them to be the Leaſt Arcs and Equal, unleſs by ſuppoſing it.

If it is ſaid, that the Point p will Move Faſter in a Mathematical Figure, when it is nearer to S, and the Point P Slower, when it is farther from it, and therefore, that the Firſt will Deſcribe an Equal Arc in a Leſſer Time than the Laſt, That will not be

True, becauſe, in Concentrical Circles, the Velocity of the Arcs is Greater, the farther you Remove them from the Center, and the Leſs the nearer they Approach to it, in the ſame Time.

If it is farther Alledged, that, ſince it has been already Proved, that the Areas PSB, pSb are Proportional to the Times, therefore the Arc PB at a Greater Diſtance from the Center S muſt be Deſcribed in a Longer Time, and pb in a Shorter; That neither has been Proved, as we have before ſhewn, nor is it Agreeable with Concentrical Circles, nor is it, as yet, made uſe of in this Demonſtration, but is Introduced afterwards, when we are Preſcribed to ſubſtitute thoſe Areas inſtead of $\frac{t^2}{T^2}$.

Fourth, As the Times of the Deſcriptions of the Arcs are Arbitrarily Aſſumed, ſo are the Forces, with which they are Deſcribed; for if pb is an Arc, which is Deſcribed with a Greater Velocity, and $P\beta$ is one, which is Deſcribed with a Leſs, tho' they are both of them Deſcribed in the ſame Time, yet the one will not be a juſt Repreſentative of the other, becauſe the Component Forces of the Projectile and Centripetal in both will be Entirely Different, and therefore we might as well have made Choice of any other; for $P\rho$ and $\rho\beta$, of which $P\beta$ is Compounded, are very Different from pr and rb, which is the Compoſition of pb, as $P\beta$ is Different from pb.

Fifth, The *Vis Inſita* or Projectile Force in P is ſuppoſed Equal to that in p or not; If Equal, pr will be $= P\rho = PR$, and then there will be an End of this Demonſtration, becauſe then likewiſe rb will be $= \rho\beta = RB$, and there will be no Difference in the Centripetal Forces, whoſe particular Reaſons and Proportions are here Endeavoured to be Aſcertain'd; If the *Vis Inſita* or Projectile Force in P is not Equal to that in p, this Philoſophy would do well to Inform us, how a *Vis Inſita* can be Intended and Remitted, or how one Certain and Immutable Force, with which Bodies would be Carry'd *in Directum*, if not otherwiſe Diverted, can be Altered.

For it is not ſufficient to ſay, that the Centripetal Force being Different in Different Parts of the Orbit makes the Projectile Force Different, ſince the Difference of the Centripetal Forces is Expreſſed by Lines Drawn Parallel to the Radius of the Curve, and conſequently, the Projectile Forces, if Equal, ought to be Expreſſed in every Part of the Curve by Equal Tangents, or elſe ſome Portion of the Centripetal Force will Enter into the Compoſition of the Tangent, and BR and br will not be the Full and Entire Expreſſions of it; Which if ſo, it follows, that $P\rho$ is not a Juſt Expreſſion of the *Vis Inſita* or the Projectile Force in P or p, or that any other is, Excepting BR, becauſe the Projectile Force of every the Leaſt Arc, whether PB or pb, muſt be Equal.

It muſt be farther ſaid, that if the Projectile Force, or the *Vis Inſita*, is Equal in every Part of the Curve, and Expreſſible by Equal Tangents, it will be ſomething Difficult to Account for the Various Velocities and Accelerations in theſe Curves from the mere Principle of a Force Acting directly towards the Center, and yet there is no other to Account for them, eſpecially, how a Body ſhould Move faſter in p than in P, when it is Nearer to the Center than when it is farther from it by a Principle of Gravity only, when the Projectile Force is Acknowledged to be the ſame. On the Contrary, if it ſhould be again Affirmed, that the Projectile Force is Different in Different Points of the Curve, it will be neceſſary to ſhew the Proportions of theſe Projectile Forces to each other, before we can pretend to Determine thoſe of the Centripetal, and we ought as well to Inquire, what Proportion PR, $P\rho$ and pr obtain amongſt themſelves, as what BR, $\beta\rho$, and br do.

Sixth, After the foregoing Suppoſitions, this Demonſtration Proceeds to tell us, that the Small Line BR is to the Small Line br in a Compound Reaſon of BR to $\beta\rho$, and of $\beta\rho$ to br, that is, $\frac{BR}{br} = \frac{BR \times \beta\rho}{\beta\rho \times br}$, and therefore by the Lemma before Cited from the *Method* of *Naſcents* and *Evaneſcents*, $BR . \beta\rho :: PBq . P\beta q :: T^2 . t^2$, ſince PB, $P\beta$ are the Leaſt Arcs, and are as the Triangles of the ſame Height BSP, βSP, that is, by the 1*ſt* and 2*d* Propoſitions of this Philoſophy, as the Times T, t, in which they are Deſcrib'd, or by the Conſtruction, as the ſame Times T, t, in which the Arcs PB, pb are Deſcribed; Again, the Small Line $\beta\rho$ is to the Small Line br, as the Cauſes, that is, as the Centripetal Forces in P and p, which Produce them, or as V to v, and therefore $\frac{BR}{br} = \frac{BR \times \beta\rho}{\beta\rho \times br} = \frac{T^2}{t^2} \times \frac{V}{v}$. But,

1st. As to the Compoſition of Reaſons, BR is to br in a Compound Reaſon of BR to PR, and of PR to br, that is, $\frac{BR}{br} = \frac{BR \times PR}{PR \times br}$, as alſo of BR to $P\rho$ and $P\rho$ to br, that is, $\frac{BR}{br} = \frac{BR \times P\rho}{P\rho \times br}$, as alſo of BR to pr and of pr to br, that is, $\frac{BR}{br} = \frac{BR \times pr}{pr \times br}$, &c. In the Firſt Caſe, ſince the Projectile Force is as the Time, $\frac{BR \times PR}{PR \times br} = \frac{V \times T}{T \times v} = \frac{BR}{br}$. In the Second, $\frac{BR \times P\rho}{P\rho \times br} = \frac{V \times t}{t \times v} = \frac{BR}{br}$. In the Third Caſe, $\frac{BR \times pr}{pr \times br} = \frac{V \times t}{t \times v} = \frac{BR}{br}$. In all which Caſes it is Evident, that nothing more is Proved, than that BR is to br, as V to v, or as the Centripetal Force in P to that in p, nor can this Demonſtration, if rightly Conſidered, Prove any more or any farther.

2d. SUPPOSING this Compoſition of Reaſons, which is here Aſſumed, that is, that $\frac{BR}{br}$ is $= \frac{BR \times \beta\rho}{\beta\rho \times br}$, it is in the Firſt Place not Evinced, that $BR.\beta\rho :: PBq.P\beta q$, becauſe the Lemma Alledged is not Prov'd; And in the next Place, becauſe $BR.\beta\rho :: PR.P\rho$ upon Account of Similar Triangles, but PR to $P\rho$ is as one Projectile Force to another, or as one Line to another, and not as the Squares of thoſe Lines.

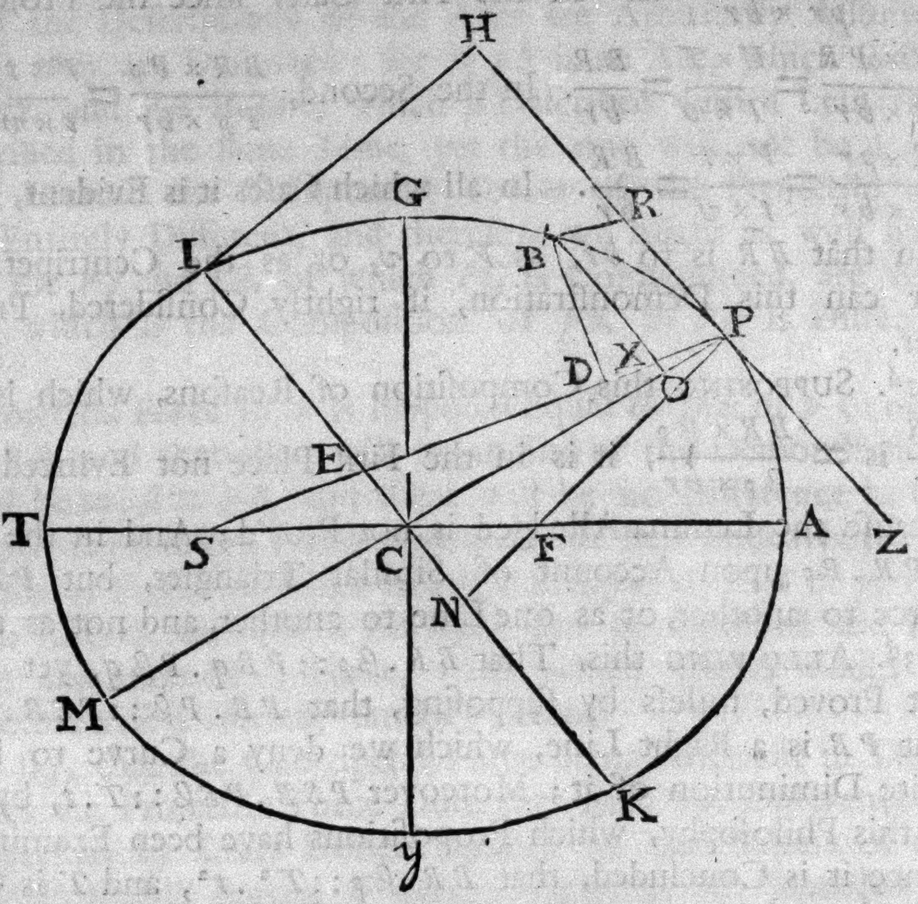
3d. ALLOWING this, That $BR.\beta\rho :: PBq.P\beta q$, yet that $PBq.P\beta q :: T^2.t^2$ is not Proved, unleſs by ſuppoſing, that $PB.P\beta :: PSB.PS\beta$, or which is the ſame, that PB is a Right Line, which we deny a Curve to be Reducible to, by any Infinite Diminution of it; Moreover $PSB.PS\beta :: T.t$, by Propoſition the *1ſt* and *2d* of this Philoſophy, which Propoſitions have been Examined and Refuted; And from hence it is Concluded, that $BR.\beta\rho :: T^2.t^2$, and T is Greater than t only, becauſe it is ſuppoſed originally to be ſo, that is, the Arc pb is ſuppoſed to be Deſcribed in a Leſs Time than the Arc PB.

4th. LASTLY it is ſaid, that $\beta\rho.br :: V.v$, but ſince PB is the Leaſt Arc, why BR ſhould not be as the Centripetal Force in P is not ſhewn, and conſequently, why BR is not to br as $V.v$, and therefore $BR.\beta\rho$ in a Proportion of Equality, which better Agrees with PB, $P\beta$, being the Leaſt Arcs, that is Equal, from whence the whole Conſtruction at P will Vaniſh, and we ſhall be only Informed, what it is to make a Diſtinction without a Difference; For it ſeems to be Impoſſible, that $\frac{BR}{br}$ ſhould be $= \frac{\beta\rho}{br} = \frac{V}{v} = \frac{T^2}{t^2} \times \frac{V}{v}$. And thus by theſe Demonſtrative ſteps we are Led to the Sum of all, that $\frac{BR}{br}$ is $= \frac{T^2 \times V}{t^2 \times v}$, when not one Particular of the whole is Proved.

SEVENTH, If $\frac{BR}{br}$ is $= \frac{T^2 \times V}{t^2 \times v}$ it muſt be owned, that $\frac{V}{v}$ is $= \frac{BR \times t^2}{br \times T^2}$ by Multiplying the Equation by t^2, and Dividing it by T^2. But when it is ſaid, That $T.t :: SBP.Sbp$ or as the Double of That, to the Double of This, or $:: SP \times BD.Sp \times bd$, here the Demonſtration again Fails; Becauſe the Firſt Proportion Depends upon what is not yet Proved, that is, the Firſt Propoſition of this Philoſophy, and the Second upon $SP \times BD$, and $Sp \times bd$ being Double of the Areas SBP and Sbp, which is not True, unleſs PB and pb, which are the Arcs of a Curve, are the ſame as Right Lines. And it is ſomething Strange and Peculiar in this New Method of Reaſoning, that there ſhould be a Difference made in the Leaſt Arcs PB, $P\beta$, or in the very Point P, for there thoſe Arcs are Naſcent or Evaneſcent, and yet that there ſhould be None made betwixt a Right Line and a Curve, or betwixt the Tangent PR and the Arc PB, as to the Triangle PBS, and on the other Hand, that there ſhould be a wide Difference made betwixt them, when we come to Conſider the Centripetal Forces BR and $\beta\rho$; This is Saying and Unſaying, making a Diſtinction, and then Rejecting it, and then Aſſuming it again, for which there can be no Account given, Excepting that of the Will and Pleaſure of the Philoſopher, who was Reſolved to Conclude in his own Way, whatever became of the Premiſes; for from hence we are Carry'd to the End of this Demonſtration in a Succeſſion of Algebraick Equations, which are Acknowledged and cannot be Conteſted.

The Law of the Centripetal Force in the Ellipſis Explained.
Sir Iſ. Newt. Princip. Lib. 1. §. 3. Prop. 11.
Dr. Gregory's Aſtronom. Lib. 1. Prop. 39. §. 5.

§. 5. The next Propoſition, which we ſhall Conſider in this Doctrine, is the Law of the Centripetal Force Tending to the Focus of an Ellipſis, in which a Body is ſuppoſed to be Revolved; Let APM be an Ellipſis, and S the Focus or Umbilicus of it, to which the Force Tends, by which a Body is Drawn from a Rectilineal Motion, which it would Deſcribe by it's *Vis Inſita* or Projectile Force, and is made to Circulate in an Elliptical Orbit, This Centripetal Force, and the Law of it, is here the Inquiry; Draw the Conjugate Axes TA, GY, which will Croſs each other in the Center C, and thro' any Point P in the Curve of the Ellipſis Draw the Tangent PZ, and the Diameter PM together with it's Conjugate ICK Parallel to the ſaid Tangent, and to ICK let fall the Perpendicular PN; Let the Parallelogram $PCIH$ be Compleated, and the Right Line IH will be a Tangent to the Ellipſis, by *Prop.* 17. *Lib.* 1. of *Conick Sections*; Join SP, which will Interſect IK in E; Thro' the Point B, which is ſuppoſed to be the next and Immediately Contiguous to P, Draw BR Parallel to PS, and BX to PZ, which will Meet PS in X and MP in O, The Centripetal Force Tending to S is by the foregoing Propoſition Reciprocally, as the Solid $\frac{SPq \times BDq}{BR}$, which, what it is in the Ellipſis, muſt be Computed and Determined from the Nature of it.



In Order to which, let the Principal *Latus Rectum* of the Ellipſis, or that, which belongs to the Greater Axis TA, be called L, the Reaſon of $L \times BR$ to BDq is Compounded of the Reaſons of $L \times BR$ to $L \times PO$, and of $L \times PO$ to $MO \times PO$, as alſo of $MO \times PO$ to BOq, of BOq to BXq, and of BXq to BDq; that is, $\frac{L \times BR}{BDq}$ is $= \frac{L \times BR \times L \times PO \times MO \times PO \times BOq \times BXq}{L \times PO \times MO \times PO \times BOq \times BXq \times BDq}$. But, 1ſt, $\frac{L \times BR}{L \times PO} = \frac{BR}{PO} = \frac{PX}{PO} = \frac{PE}{PC}$, Becauſe XO is Parallel to EC, $= \frac{AC}{PC}$, For PE is $= AC$ by a foregoing Lemma, which there is no occaſion particularly to Conſider here, and which is at Preſent Granted. 2*d.* $\frac{L \times PO}{MO \times PO}$ is $= \frac{L}{MO}$. 3*d.* $\frac{MO \times PO}{BOq}$, by *Prop.* 21. *Lib.* 1. of *Conick Sections* is $= \frac{MCP}{ICq} = \frac{CPq}{ICq}$. 4*th.* $\frac{BOq}{BXq} = \frac{1}{1}$, or the One is Equal to the Other, becauſe the Points B and P Coincide or come together, by which means BO is $=$ to BX. 5*th.* $\frac{BXq}{BDq} = \frac{PEq}{PNq}$, becauſe the Triangles BDX, PNE are Equiangular, upon the Account of the Angles D and N being Right ones, and BXD, PEN Alternate ones from the Parallels BX, EN, but $\frac{PEq}{PNq} = \frac{CAq}{PNq}$, Becauſe $PE = CA$ by the aforeſaid Lemma; Farther, by *Prop.* 72. *Lib.* 4. of *Gregory à Sancto Vincentio* $GC \times CA = PCIH = IC \times PN$, that is, $CA . PN :: IC . GC$, and therefore $CAq . PNq :: ICq . GCq$, and conſequently, $\frac{CAq}{PNq} = \frac{ICq}{GCq} = \frac{BXq}{BDq}$.

From whence, namely from the ſeveral Steps, thro' which we have Gone, ſince $\frac{L \times BR}{BDq}$ is $= \frac{L \times BR \times L \times PO \times MO \times PO \times BOq \times BXq}{L \times PO \times MO \times PO \times BOq \times BXq \times BDq}$, and ſince $\frac{L \times BR}{L \times PO}$ is $= \frac{AC}{PC}$, $\frac{L \times PO}{MO \times PO} = \frac{L}{MO}$, $\frac{MO \times PO}{BOq} = \frac{CPq}{ICq}$, $\frac{BOq}{BXq} = \frac{1}{1}$, and $\frac{BXq}{BDq} = \frac{ICq}{GCq}$, It follows, that $\frac{L \times BR}{BDq}$ is $= \frac{AC \times L \times CPq \times 1 \times ICq}{PC \times MO \times ICq \times 1 \times GCq} = \frac{AC \times L \times PCq}{PC \times MO \times GCq}$, Alſo by *Prop.* 13. *Lib.* 1. of *Conick Sections*, $AC \times L = 2GCq$, and therefore $\frac{L \times BR}{BDq}$ is $= \frac{2GCq \times PCq}{PC \times MO \times GCq} = \frac{2PC}{MO}$;

But ſince the Point B, in the Preſent Caſe, is Next and Immediately Contiguous to the Point P, O is very little or nothing Diſtant from it, that is, MO is $= 2PC$, and therefore $L \times BR = BDq$; Conſequently, ſince the Centripetal Force is, as has been in the Preceding Propoſition Proved, Reciprocally as the Solid $\frac{SPq \times BDq}{BR}$, and ſince in the Ellipſis BDq is $= L \times BR$, the Centripetal Force in the Ellipſis will be Reciprocally, as $\frac{SPq \times L \times BR}{BR} = SPq \times L$, and ſince L is a Conſtant and Invariable Quantity, the Centripetal Force in the Ellipſis will be Reciprocally as SPq, that is, Reciprocally as the Square of the Diſtance of the Body Revolved from the Focus or Umbilicus, to which the Centripetal Force Tends. *Q. E. D.*

The ſeveral Objections which lie againſt the foregoing Demonſtrations.

§. 6. Wonderful ſure muſt be the Name or Power of Demonſtration, which can Force the Aſſent without Convincing the Underſtanding, and yet this ſeems to be the Preſent Caſe; For,

First, That the Centripetal Force Tending to S is Reciprocally, as the Solid $\frac{SPq \times BDq}{BR}$ is far from being ſhewn, we have on the Contrary Evinced, that the Reaſoning, by which that Proportion is Concluded, is Sophiſtical, Deſultory, and Falſe upon ſeveral Accounts, notwithſtanding which, the whole Strength of the Preſent Demonſtration Entirely Reſts and Depends upon the Truth and Certainty of that Proportion.

Second, The next Thing neceſſary to this Demonſtration is to make $L \times BR = BDq$, ſo that SPq may ſtand by it ſelf; and this is done in ſo Looſe and Arbitrary a Manner, by Begging ſo many Uncertainties for Real Truths, and Subſtituting in the Room of others ſo many Quantities, which are better Fitted for the Purpoſe of Reducing BDq to $L \times BR$, and which yet is not Effected, that it may be called any Thing rather than a Mathematick Calculation of the Law of the Centripetal Force of a Body Revolving Round the Focus of an Ellipſis.

Thus, First, $\frac{L \times BR}{BDq}$ is ſaid to be $= \frac{L \times BR \times L \times PO \times MO \times PO \times BOq \times BXq}{L \times PO \times MO \times PO \times BOq \times BXq \times BDq}$, and ſo it is, becauſe $\frac{L \times PO \times MO \times PO \times BOq \times BXq}{L \times PO \times MO \times PO \times BOq \times BXq}$ is $= \frac{1}{1}$, which multiplyed into $\frac{L \times BR}{BDq}$ is certainly $=$ to $\frac{L \times BR}{BDq}$, But then we may as well ſay, that $\frac{L \times BR}{BDq}$ is $= \frac{L \times BR \times L \times PX \times MP \times PX \times BXq}{L \times PX \times MP \times PX \times BXq \times BDq}$, or $\frac{L \times BR}{BDq} = \frac{L \times BR \times L \times PS \times MP \times PE \times ICq \times IEq}{L \times PS \times MP \times PE \times ICq \times IEq \times BDq}$.

Second, Granting yet this Compoſition of Reaſons, $\frac{L \times BR}{L \times PO}$ is ſaid to be Equal to $\frac{BR}{PO} = \frac{PX}{PO} = \frac{PE}{PC}$, Becauſe XO is Parallel to EC, $= \frac{AC}{PC}$, Becauſe PE is $= AC$ by the

Lemma Cited. But ſince, by the Fourth Article of the Compoſition of Reaſons in the Preceding Demonſtration BO is $= BX$, why $\frac{PX}{PO}$ ſhould be Equal to $\frac{PE}{PC}$ or $\frac{AC}{PC}$ rather than $PO =$ to PX cannot be ſhewn, and conſequently, why $\frac{PX}{PO}$ ſhould not be $= \frac{1}{1}$; Or on the Contrary, if $\frac{PX}{PO}$ is not in a Reaſon of Equality, then $\frac{BOq}{BXq}$ in the ſaid Fourth Article is not.

Third, $\frac{BXq}{BDq} = \frac{PEq}{PNq}$, becauſe upon Account of the Similar Triangles BDX, PNE, $BX.BD::PE.PN$, but if we may Take BO inſtead of BX, it will be as $BO = BX.BD::PC = PE.PN$, from whence $PC = AC$, and therefore again, as before, $\frac{PX}{PO} = \frac{AC}{PC} = \frac{1}{1}$, and AC and PC Two very Different Semiaxes of the ſame Ellipſis, or even AC and GC the Semiaxis Principal and Conjugate or Tranſverſe will be Equal, and the Ellipſis changed into a Circle, for the Point P may be taken, as this Demonſtration is General, in any Part of the Elliptical Curve, or elſe it is not General, and therefore of no Significance or Importance at all.

Fourth, Conſequently, tho' PE is $= AC$ by the Lemma Cited, PC is not, and yet according to what foregoes PC may be likewiſe $=$ to AC; Again $\frac{CAq}{PNq}$ is $= \frac{ICq}{GCq}$, becauſe PE is $= CA$, but if we take PC in the Room of PE, will $\frac{PCq}{PNq}$ be $=$ to $\frac{ICq}{GCq}$? And yet this may be Affirmed, if BX is $= BO$.

From all which it is very Apparent, that this Philoſophy uſes theſe Naſcent or Evaneſcent Quantities juſt as it Pleaſes, ſometimes there ſhall be no Difference betwixt them, and at other Times a very Senſible one, then it ſhall again Vaniſh, and afterwards Riſe into a Reaſon and Proportion, as Regularly and Mathematically, as if there was ſomething more than Notion in it; And upon the Whole, which is a little Admirable, all this Pompous Compoſition of Forces is Reduced to a Proportion of Equality, and $\frac{L \times BR}{BDq}$ is $= \frac{1}{1}$.

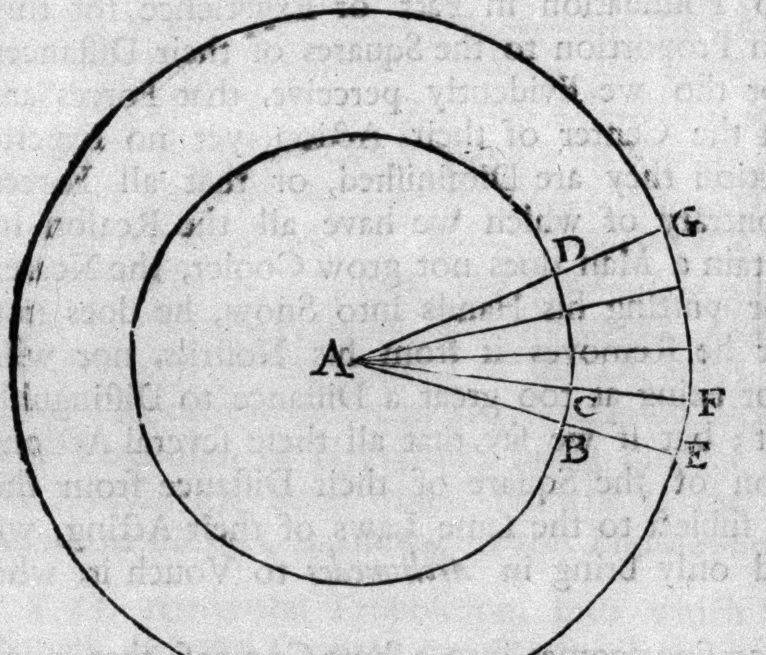
Fifth, After the ſeveral Reaſons, which are Subſtituted in the ſtead of the Former, $\frac{L \times BR}{BDq}$ is ſaid to be $= \frac{AC \times L \times CPq \times BOq \times ICq}{PC \times MO \times ICq \times BXq \times GCq}$, and ſince $\frac{BOq}{BXq}$ is $= \frac{1}{1}$, or $BO = BX$ and $\frac{ICq}{ICq} = \frac{1}{1}$, $\frac{L \times BR}{BDq}$ will be $= \frac{AC \times L \times PCq}{PC \times MO \times GCq}$. But in the 1ſt Place, if $\frac{BOq}{BXq}$ is $= \frac{1}{1}$, we have ſhewn that $\frac{AC}{PC}$ may be $= \frac{1}{1}$, and $\frac{PCq}{GCq} = \frac{ACq}{GCq}$, and conſequently, $\frac{L \times BR}{BDq} = \frac{L \times ACq}{MO \times GCq}$, from whence there could be no farther Progreſs to a Concluſion of what this Demonſtration pretends to Affirm. In the 2*d* Place, if $\frac{BOq}{BXq}$ is not $= \frac{1}{1}$, $\frac{L \times BR}{BDq}$ will not be $= \frac{AC \times L \times PCq}{PC \times MO \times GCq}$, but $= \frac{AC \times L \times BOq \times PCq}{PC \times MO \times BXq \times GCq}$, which will not again ſuit with the following Concluſion. In the 3*d* Place we muſt likewiſe ſay, that ſince, becauſe $BOq = BXq$ and $ICq =$ to it ſelf, they are Removed out of the Compoſition of Reaſons, it is not Evident, why Originally $\frac{L \times PO \times MO \times PO \times BOq \times BXq}{L \times PO \times MO \times PO \times BOq \times BXq}$ ſhould not, and then $\frac{L \times BR}{BDq}$ would be $= \frac{L \times BR}{BDq}$, which would not ſignify much to the Preſent Demonſtration.

Sixth, At Length after a great Deal of Artifice in Shuffling and Changeing of Reaſons, it is found, that $\frac{L \times BR}{BDq}$ is $= \frac{2PC}{MO}$, but then a new Conceſſion is wanted, and therefore it is Affirmed, that $2PC$ is $= MO$, or, that PO is $= 0$; and ſince $BX = BO$, $PX = BR$ is $= 0$, from whence $\frac{L \times BR}{BDq}$ is $= 0$, and conſequently, this whole Demonſtration in the laſt Reſult will in Reality and in Truth amount to Nothing.

Seventh, Since $L \times BR = BDq$ is $= 0$, $\frac{SPq \times L \times BR}{BR}$ in the Ellipſis will be $=$ $SPq \times 0 = 0$, and ſo this Demonſtration Ends with telling us, that it has Demonſtrated Nothing at all. *Q. E. D.*

The Demonſtration, as Extended to all Actions Propagated from the ſame Center, Conſidered.
Dr. Halley's Miſcellanea Curioſa.
Dr. Keill's Intr. ad Ver. Phyſ. Lect. 1.
Dr. Gregory's Aſtronom. Prop. 48. Lib. 1.

§. 7. And notwithſtanding this Appears to be, as I have Repreſented it, ſo fond of late have Philoſophers been of the Cogency and Strength of this Reaſoning, that they have Extended it to all Actions of Light, Heat, Cold, Smells, &c. which are Propagated from a Center, as well as of Attraction or Gravitation, to which it is here only Confined, but not being willing to make uſe of a Projectile and a Centripetal Force upon which this Demonſtration Depends, becauſe they knew of no ſuch Forces in Light, Heat, Cold, or Smells, they have Contrived another Way to let us into this Secret, which is, by ſhewing that the Rays AG, AF, AE, in a Sphere, are more Cloſe and Compact nearer the Center, and more Diffuſed and Diſperſed in a farther Removal from it, in that Proportion, which the Spherical Surface GE has to that of DB; and ſince, by *Archimedes de Sphæra & Cylindro*, it is Proved, that Spherical Surfaces are to each other, as the Circles Deſcrib'd by the ſame Radius's, and ſince thoſe Circles are in a Duplicate Reaſon of the ſaid Radius's, it follows, that the Compaction, Denſity, or Spiſſitude of the Rays in DB, is to the Denſity or Spiſſitude of them in GE, as the Square of AG or AE to the Square of AD or AB, and ſince the Intenſion or Force of any Action is in Proportion to the Compaction or Spiſſitude of the Rays, ſuch Force or Intenſion will be Reciprocally, as the Squares of the Diſtances.



But First, How far this Demonſtration is Applicable to Gravity, we have already Conſidered in the Firſt Volume of our *Principles* of *Natural Philoſophy*, and as there, ſo here likewiſe we cannot but Affirm, that it is an Abſtracted Reaſoning, and ſo far True, as it is *Archimedes*'s, that Spherical Surfaces are in a Duplicate Reaſon of their Semidiameters. If yet we are willing to Extend it any farther, what we ſay is Precarious and without a Foundation in Reaſon or in Fact.

For Second, It is not Evinc'd, that the Spiſſitude of the Rays in DB and GE is Reciprocally, as the Spaces Poſſeſſed by them, and that therefore in DB they are more Compact and Denſer, and in GE more Dilated and Diffuſed, becauſe if ſo, it would not only Arrive to Rays of Action, but to thoſe of Space, and the Space DB would be Thicker and Denſer than GE, which is not Acknowledged, tho' it may Perhaps be True.

Besides, the Spiſſitude of the Rays is Reciprocal to the Spaces, which they Poſſeſs upon the Suppoſition, that there is the ſame Number of Rays in DB and GE, as likewiſe in a Similar Arc of the Smalleſt Circle Drawn round A, and conſequently, ſuppoſing DB to be Entirely full of Rays, the ſame Rays can Poſſeſs no more Space in GE than in DB, if therefore a Space is taken out from EG Equal to DB, all the Reſt muſt be Vacuity, to which theſe Rays do not Reach; from whence it will follow, that if *GE* Repreſents the Earth's Orbit, and the Spherical Surface produced by it, and *DB* ſuch a Surface, the neareſt we can Imagine to the Sun in *A*, as the Spherical Surface of the one is ſeveral Millions of Times Greater than the other, ſo there will be only in the Spherical Surface of the Earth's Orbit a Space Illuminated Equal to the next Spherical Surface to the Sun, and all the ſeveral Millions and Millions of Space beſides will have no Rays at all to Pervade them: And the ſame may be ſaid of other Actions, that if this Reaſoning were True, they would not be Diſperſed thro' all Space, which they are ſuppoſed to be, but at a Conſiderable Diſtance from their Center they would be Perceived at Certain Intervals, and by Interruptions, as at *E*, *F*, and *G*, without any Uniformity of their Diffuſion.

FARTHER, Not only the Number of Rays is ſuppoſed to be the ſame in *GE* and *DB* to make the Spiſſitude of them Reciprocal to the Spaces, which they Poſſeſs, but the Force and Action of them is ſuppoſed to be as the Spiſſitude of the Rays, that is, the Action of the Ray at *G* is Equal to the Action of it at *D*, and it is not Diminiſhed by it's Diſtance, for if it were, the Diminution of it's Force need not be Conferred upon the Rarity or Dilatation of the Rays, ſince every Ray would be Diminiſhed in it's Force ſeparately, and by it ſelf, the farther it was Carry'd from the Center of it's Action; Beſides, if every Ray was Diminiſhed in it's Force, the farther it Receded from the Center of it's Action, the Diminution of Force would not be as the Spiſſitude of the Rays was Diminiſhed, which this Demonſtration Affirms, but in a Compound Reaſon of the Diminution of the Force of the Rays, and of the Diminution of the Spiſſitude of them; On the Contrary, if every Single Ray, conſidered by it ſelf, is the ſame in it's Force at a Greater or Leſs Diſtance from the Center of it's Action, which I ſay is here ſuppoſed, That of all Things ſhould have been Proved, becauſe it is a Paradox, and will want very Fine and Subtile Arguments to ſupport it.

WE have alſo ſaid, that there is no Foundation in Fact or Experience for this Aſſertion, That Forces are Diminiſh'd in Proportion to the Squares of their Diſtances from the Center of their Action; For tho' we Evidently perceive, that Forces are Diminiſhed the farther they are from the Center of their Action, yet no Experiments yet have ſhewn in what Proportion they are Diminiſhed, or that all Forces are ſubject to the ſame Laws; The Contrary of which we have all the Reaſon in the World to believe is True; 'Tis Certain a Man does not grow Cooler, the Nearer he comes to the Fire, nor Warmer for putting his Hands into Snow, he does not Smell *Aſſa Fœtida* Stronger, the farther he Removes it from his Noſtrils, nor will he Hear a Conſort of Muſick better for being at too great a Diſtance to Diſtinguiſh the Variety of Notes, which Compoſe it; but if we ſay, that all theſe ſeveral Actions are Diminiſhed in the ſame Proportion of the Square of their Diſtance from the Center of them, and that they are all ſubject to the ſame Laws of their Acting, we ſhall Affirm a very great Falſhood, and only bring in *Archimedes* to Vouch it, who never ſaid any ſuch Thing.

ALL, which can be ſaid upon this Occaſion, comes into a ſhort Compaſs, that every Action is the Strongeſt at the Center of it, that it is afterwards Weaker by Receding from thence, and by being Diffuſed into a Larger Space, each part of which it Repleniſhes and Fills, that this is not done by Rectilineal Rays, but by a Diffuſion of the Force, that this Diminution of Action upon both theſe Accounts is Various according to the Nature, Temper, and Genius of the Agent and Patient, which Nature and Temper of the Agent and Patient is to be Determined from the Degree of the Expanſive and Contractive Force, which belongs to them.

The Corollaries from the foregoing Propoſition need not to be Conſider'd. Dr. Gregory's Aſtronom. Prop. 39. Coroll. 1, 2, 3, 4, 5, and 6. Lib. 1.

§. 8. BUT to Return to the Phyſical Aſtronomy, from which we have thus far Digreſſed; As to the Corollaries, which are Derived from the Preceding Propoſition, in Reſpect of the Ellipſis being Changed into a Circle by the Focus's Approaching infinitely near to each other, or into a Right Line by their Approaching infinitely near to the Vertices, as alſo into a Parabola, if one of the Focus's Remains Fix'd, and the other Removes to an Infinite Diſtance from it, or into an Hyperbola, ſuppoſing the one is Fixt, and the other is Carry'd to more than an Infinite Diſtance from it, ſo that now the Vertices *A* and *T* ſhould lie betwixt the Foci *S* and *F* with their Curves bent Contrary ways; It is Affirmed, that the ſame Law obtains in all theſe Caſes, which has been before Demonſtrated; That is, in this Doctrine a Right Line, a Circle, a Parabola, and Hyperbola are all to be Reduced to a kind of Ellipſes, tho' their Properties are never ſo Different and Various, and all this is Done in Order to bring them under the ſame Law of the Centripetal Force, which is ſaid to be Obſerved in the Ellipſis; againſt which there might be ſeveral Objections Alledged, into which Diſpute there is yet no Occaſion to Enter, ſince the aforementioned Law of the Centripetal Force is not proved to Obtain in Ellipſes themſelves.

§. 9. The next Propoſition, which we ſhall mention is, that if ſeveral Bodies Revolve about a Common Center, and the Centripetal Force is Reciprocally as the Square of the Diſtance from the Center, the Squares, it is ſaid, of the Periodical Times in Ellipſes are as the Cubes of the Tranſverſe or Greater Axes, or, which is the ſame, the Periodical Times are in a Seſquiplicate Proportion of the ſaid Axes; which Propoſition there is no Occaſion particularly to Conſider, unleſs the Centripetal Force is Reciprocally as the Square of the Diſtance from the Center, which is not hitherto Evinced; Beſides which, there are other Things, which may juſtly be Objected againſt this Demonſtration, which we ſhall now Paſs over, till the Way is Clear'd and made Plain to the Preſent Concluſion, and for the ſame Reaſon the Corollaries of this Propoſition concerning the Circle or any other Orbits are Omitted, for if the Grand Law of the Centripetal Force is not True, it will be in Vain to Expect any Thing of Conviction and Certainty from Reaſonings, which Depend upon a Wrong or a Precarious Foundation.

That the Squares of the Periodical Times in Ellipſes are as the Cubes of the Tranſverſe or Greater Axes, not Proved.
Sir Iſ. Newt. Princip. Prop. 15. Lib. 1.
Dr. Gregory's Aſtronom. Prop. 40. Lib. 1.

§. 10. Upon the ſame Account, it will not be neceſſary to Examine into the following Propoſition, that, ſuppoſing the ſame Law of the Centripetal Force, as before, the Velocities of Bodies, Revolving about a Common Center, in any Points Given, are in a Reaſon Compounded of a Subduplicate Reaſon of the Principal *Latus Rectum*'s, belonging to the Lines, which they Deſcribe, and of an Inverſe Reaſon of the Perpendiculars, Drawn from the Common Center to the Tangents of the Points, where the Bodies are; Becauſe that Law of the Centripetal Force is Deny'd, and all the Concluſions, which are made from it; Moreover, we Affirm, that here likewiſe lie ſome Particular Objections againſt this Demonſtration upon the Account of the Velocities, which are Introduced in it, and of which we have Diſcourſed in other Parts of the Preſent Philoſophy. We muſt farther add in Reſpect of the Corollaries here, and of thoſe, which belong to the Former Propoſitions, that ſeveral of them will be the ſame, tho' the Law of the Centripetal Force was Different from what is Pretended to be Demonſtrated; Thus, tho' the Centripetal Force was not Reciprocally, as the Squares of the Diſtances, but as the Cubes or Biſquares, or any other Proportion of them, the Reaſoning would be much the ſame, as to the Circles, Parabolas, or Hyperbolas being Ellipſes, for if any Different Law obtain'd in the Ellipſis, the ſame would likewiſe in the Circle, Parabola, or Hyperbola, conſider'd as Ellipſes, according to this Philoſophy.

That the Velocities are in any Points given in a Reaſon Compounded of a Subduplicate Reaſon of the Principal Latus Rectum's *and of the Inverſe Reaſon of the Perpendiculars let down to the Tangents of the Points where the Bodies are, not Proved.*
Sir Iſ. Newt. Princip. Prop. 16. Lib. 1.
Dr. Gregory's Aſtronom. Prop. 41. Lib. 1.

§. 11. Another Propoſition, into which we ſhall Inquire, is, that the Primary Planets and the Comets are Drawn from a Rectilineal or Projectile Motion, and made to Revolve in Elliptical Orbits by Forces, which Tend to the Sun, and are Reciprocally, as the Squares of their Diſtances from it's Center.

The Law by which the Primary Planets are kept in their Orbits, not Certain.
Sir Iſ. Newt. Princip. Prop. 2. Lib. 3.
Dr. Gregory's Aſtronom. Prop. 42. Lib. 1.

As to the Planets, the Former Part of the Propoſition is ſaid to be Proved from *Phænomenon* the 5th, *Lib.* 3. which Informs us, that the Primary Planets Deſcribe Areas Proportional to the Times by Radius's Drawn not to the Earth, but to the Sun, becauſe, in Reſpect of the Earth, they are ſometimes Progreſſive, then Stationary, and at other Times Retrograde, whereas, in Reſpect of the Sun, they are always Progreſſive, ſo as in Equal Times to Deſcribe Equal Areas; and from *Prop.* 2. *Lib.* 1, which tells us, that every Body, which is Moved in any Curve Line Deſcrib'd in a Plane, and by a Radius Drawn to an Immoveable Point, or a Point, which has an Uniform Progreſſion, Performs Areas about that Point Proportional to the Times, is Urged and Impelled by a Centripetal Force Tending to ſuch Point.

The Second Part of this Propoſition is Affirmed alſo to be Proved from *Phænomenon* the 4th, *Lib.* 3, which Relates, that the Periodical Times of the Primary Planets, and of the Earth Round the Sun, are in a Seſquiplicate Reaſon of their Middle Diſtances from it, or which is the ſame, that the Squares of the Periodick Times are as the Cubes of the Diſtances, and from *Prop.* 4. *Lib.* 1, which alledges, *Corol.* 6, that if the Periodick Times are in a Seſquiplicate Reaſon of the Radius's, the Centripetal Forces will be Reciprocally, as the Squares of the Radius's.

However, This Part of the Propoſition is reckoned likewiſe to be ſtrictly Demonſtrated from the Quieſcence of the Nodes and the Apſides, Becauſe the Leaſt Deviation from the Duplicate Reaſon, by *Prop.* 45. *Lib.* 1. *Corol.* 1, would produce a very ſenſible Motion of the Apſides in each Revolution, and in ſeveral a very Enormous one.

This Part alſo of the Propoſition is ſaid to be Proved from it's being Acknowledged, that the Planets are Revolved in Ellipſes, and from being before ſhewn, that the Law of Bodies, Revolving in Ellipſes, is, that their Centripetal Forces ſhould be Reciprocally, as the Squares of the Diſtances. And as to Comets, the ſame is Affirmed of them, becauſe they are ſuppoſed to Deſcribe Ellipſes, which by the Infinite Diſtance of the Focus's are Changed into Parabolas.

The Arguments, which may be brought againſt this Account of the Revolution of the Primary Planets.

§. 12. First, The *Pythagorick* or *Copernican Syſtem* is here Suppoſed and not Proved, and the Diſpute betwixt that and the *Ptolemaick* and *Tycho Brahe's* is left where it was, and nothing Propoſed in the *Phænomenon*, but that the Planets are Progreſſive, Stationary and Retrograde to us on the Earth, which would not appear ſo, if we were in the Sun, which the Aſſertors of all the Syſtems no doubt Equally knew, and which yet did not hinder, but was indeed the Occaſion of their ſeveral Hypotheſes; and as to the Equable Deſcription of the Areas about the Sun, it is no more an Argument for the Truth of the *Copernican Theory*, than the Unequal Deſcription of the Orbits or Curves ſhould be an Argument againſt it, the Equality of the Deſcription of Areas being of no Advantage, that I know of, to an Hypotheſis, unleſs we could ſhow a Reaſon, why it ſhould be ſo, in Preference to an Equal Deſcription of the Curve.

Nay, Imagining it to be Fact, that the Areas were Deſcrib'd from the Aphelium to the Perihelium of the Planet in a Double or Triple, a Duplicate or a Triplicate, or in any other Arithmetical or Geometrical Proportion of the Times, it would be to the full as Beautiful to an Hypotheſis, as if they were Deſcrib'd in a Proportion of Equality, tho' I am apt to ſuſpect, that this Phænomenon of Equal Areas being Deſcribed in Equal Times is not exactly True, and that it is only a Fancy or Notion Invented to ſerve ſome Explanations in Aſtronomy, which *Kepler* began, and whom the Reſt have Followed.

'Tis true by this Equable Deſcription of the Areas, the Velocity of the Planet in the Perihelium, and it's ſlow Progreſs in the Aphelium is Immediately Inferred, but if thoſe and other Phænomenons may be Accounted for upon Different Suppoſitions, it is not ſo Evident, why the Equable Deſcription of Areas about the Sun ſhould Determine us to Prefer the *Copernican* to any other Hypotheſis; I do not ſay this, that I would be thought rather to Incline to the *Ptolemaick* or *Tycho's* than *Copernicus's*, but only to ſhew, that the Preſent *Phyſical Aſtronomy* leaves that Controverſy very much, where it found it, and raiſes it's own Structure upon the Conceſſion, that the *Copernican Syſtem* is True, without Confirming it by any Invincible Demonſtrations, unleſs what may Reſult from it's future Reaſonings.

Second, After the *Phænomenon*, we are Referr'd to *Prop.* 2. *Lib.* 1, for a Proof of the Firſt Part of this Propoſition, which has been already Conſidered and Examined, and has been ſhewn to fall ſhort of, what is Pretended, a Demonſtration; Since it cannot be Proved, that a Curve is Deſcribed by thoſe Two Forces, a Projectile and a Centripetal; To which we ſhall add, that it may as well be Performed by an Expanſive Force from the Sun in the Preſent Caſe, as a Centripetal one to it, of which we ſhall afterwards Diſcourſe.

Third, The Second Part of this Propoſition is as illy Proved, as the Former, becauſe the Phænomenon, that the Squares of the Periodick Times are as the Cubes of the Diſtances, is altogether Uncertain, for tho' the Periodick Times may be well enough Agreed on amongſt Aſtronomers, yet the Diſtances of the ſeveral Planets from the Sun are not ſo, and even that of the Earth from it admits of Variations from the beſt Obſervers; Becauſe we are not capable by any Inſtruments Preciſely and Exactly to Determine them: But the Diſtances of the Planets from the Sun we have more particulary Examined into in another Place.

GRANTING all which, we have ſhewn, that *Prop.* 4. *Lib.* 1. and *Corol.* 6, which ſays; that if the Periodick Times are in a Seſquiplicate Reaſon of the Radius's, the Centripetal Forces will be Reciprocally, as the Squares of the Radius's, as well as all the other Corollaries belonging to the ſame Propoſition, want that Evidence, which might be Expected from a Demonſtration of them, and which therefore we need not here Repeat. But ſtill in Juſtification of this Reaſoning it is ſaid, that the Quieſcence of the Nodes and the Apſides is a full Conviction of the Truth of it, ſince the leaſt Deviation from a Duplicate Proportion, by *Prop.* 45. *Lib.* 1. *Corol.* 1, would produce an Evident Motion in them, even in each Single Revolution.

THIS may ſeem to be a very forcible Argument for the Validity of the Preſent Doctrine, but if we Conſider, that the Propoſition here Cited is ſtrictly Connected with, and Depends upon that, which we have Explained in §. 5. of this Chapter, and which Affirms, that the Law, by which a Body Revolves in the Ellipſis, is, that it's Centripetal Force is Reciprocally, as the Square of it's Diſtance, we ſhall eaſily ſee, that it ſignifies no more, than to ſay, that if an Immoveable Ellipſis is Deſcribed by the Duplicate Proportion, a Moveable Ellipſis will not be; but this is no Proof, that an Immoveable Ellipſis is Deſcribed by that Duplicate Proportion; a Deviation from a Duplicate Proportion makes the Ellipſis Moveable, upon the Suppoſition, that a Duplicate Proportion belongs to an Immoveable one, but no one will therefore from ſuch a Deviation ever ſurely Prove, that a Duplicate Proportion belongs to an Immoveable one, and yet this is the Strength and Solidity of the preſent Argument.

LASTLY, As to the Law of the Centripetal Force, by which an Ellipſis is ſaid to be Deſcribed, and which is thought to be Reciprocally, as the Square of the Diſtance, we have fully Examined that Propoſition in §. 6. of this Chapter. So that all the Demonſtration, which we have of this Grand and Magnificent Propoſition in the Phyſical Aſtronomy concerning the Revolution of the Primary Planets, Reſts either upon Phænomenons, which cannot be fully Acknowledged, or upon Propoſitions which are not Evinced, or on Deductions from them, which are not Rational and Juſt, and for which we may deſervedly ſuſpend our Aſſent to it, at leaſt till theſe Objections are Anſwer'd and Cleared.

An Account of the Method of Proceeding in this Philoſophy, and the Reaſons againſt it in General.

§. 13. I ſhall only here add, that it has been for ſome Time a Myſtery to me in this Philoſophy, what ſhould be the Occaſion of Introducing ſo New, and ſo Looſe, and Latitudinarian a Way of Reaſoning in it, and ſo Apparently Forced and Strained, and what ſhould be the Spring and Riſe of the Whole being Caſt into the Preſent Model; Which upon a farther Conſideration and Inquiry ſeems Obvious and Plain.

Sir Iſ. Newt. Pref. Lib. 3. De Mundi Syſtemate.

FOR, This Philoſophy deſigning Chiefly and Principally to give an Account in a Mechanical Way of the Revolutions of the Heavenly Bodies, it obſerved, what were acknowledged to be the General Phænomenons or Appearances of them; Namely,

Sir Iſ. Newt. Princip. Phænom. Lib. 3.

1st. THAT the Primary Planets Deſcrib'd Ellipſes about the Sun, which was Placed in one of the Focus's of ſuch Ellipſes.

2d. THAT the Secondary Planets Deſcrib'd Ellipſes about the Primary ones, which were likewiſe Placed in one of the Focus's of ſuch Ellipſes.

Phænom. 1, 2. Lib. 3.

3d. THAT the Secondary Planets about *Jupiter* and *Saturn* Performed Areas Proportional to the Times of their Deſcription, and that the Squares of their Periodical Times were as the Cubes of their Diſtances, or which is the ſame, that their Periodick Times were in a Seſquiplicate Proportion of the ſaid Diſtances.

Phænom. 4, 5. Lib. 3.

4th. THAT the Primary Planets and the Earth about the Sun Perform'd Areas Proportional to the Times of their Deſcription, and that the Squares of the Periodical Times were as the Cubes of their Middle Diſtances from the Sun, or, which is the ſame, that their Periodical Times were in a Seſquiplicate Proportion of the ſaid Middle Diſtances.

Phænom. 6. Lib. 3.

5th. THAT the Moon about the Earth Performs Areas Proportional to the Times of their Deſcription.

FIRST, As to theſe Phænomenons themſelves, tho' Propounded by *Kepler*, and ſince Aſſented to by moſt Aſtronomers, We ſay, the Uncertainty of Aſtronomical Obſervations in General is ſo Great, that methinks it is but a very fallible Foundation to Build a whole Syſtem of Philoſophy upon; For *1ſt*, As we before Mentioned, however known the Periodical Times of the Primary and Secondary Planets are, the Diſtances of the Firſt from the Sun, and the Laſt from the Primary Planets are Diſputable and Unaffirmed; Beſides, 2*d*, there is not ſuch Evidence for the Areas being Proportional to the Times of their Deſcription in the Revolution of the Primary or Secondary Planets, as makes it Inconteſtable and beyond Contradiction; Nor farther, 3*d*, Does the Proportion of the Periodick Times being in a Seſquiplicate one of the Diſtances ſo manifeſtly Appear, that it ſhould be Aſſumed as a Demonſtrative Truth, for Reaſons before Alledged; And it is ſomething Strange, and looks like a Colluſion in the Beginning of this Philoſophy, that when it Confeſſes this to be the Proportion in the Secondary Planets, becauſe the Orbits are nearly Circular, in the Primary ones it is obliged to take the Middle Diſtances only, becauſe the Orbits are more Elliptical, and this Proportion could not Anſwer all the Diſtances of the Planets Revolving in ſuch Orbits.

And yet theſe are the Grand Truths, upon which the Whole of this Philoſophy ſtands, and which ſeem to be no more at the Beſt than Aſſertions of *Kepler*, to which other Aſtronomers have thought fit to Agree, becauſe Two or Three plain Phænomenons, as they were Imagin'd, would better be Explained, than a Thouſand Various and Different ones; But ſurely we ſhould not take our Notions of all Nature from fallible Obſervations in Aſtronomy, and Obſervations Adjuſted and Reduced by Artifice and Contrivance to what are Termed Phænomenons in the Heavens. Nay, ſuppoſing theſe Phænomenons in the Heavenly Bodies to be Accurate and True, and not Framed and Modelled by the Aſtronomer to his own Purpoſes, is it Juſt and Reaſonable to Preſcribe Laws to Nature, and all the Beings in it from them, or from what we continually Know and Experience to Dictate to their Actions? However it is Plain, that upon theſe ſuppoſed Truths or Phænomenons the Preſent Philoſophy is built, and it may be properly ſaid to be an Account or Explanation of them.

Sir Iſ. Newt. Princip. Prop. 1. Lib. 1.

Def. 3. & 5.

Sir Iſ. Newt. Princip. Lex. 1.

Sir Iſ. Newt. Princip. Leg. Corol. 1.

Sir Iſ. Newt. Lem. 3. Corol. 4. De Methodo Rationum Primarum & Ultimarum.

Second, The next Thing therefore, which was to be Atchieved, was to ſhew, what Forces would be Requiſite to Deſcribe a Figure, whoſe Areas ſhould be Proportional to the Times of their Deſcription, and this Introduced *Prop.* 1. of this Philoſophy; and the Deſcription of theſe Areas being to be made about an Immoveable Center, from hence Aroſe the Centripetal Force and the *Vis Inſita*, and conſequently, Definitions the 3*d* and 5*th* were Eſtabliſhed; but the *Vis Inſita* being only Defined to be a Power in Matter of Reſiſting, by which every Body, as far as in it was, Perſevered in it's State of Reſt or of Motion *in Directum* or Strait forward, ſuch a Definition could ſignify nothing to the Reality of the Thing, unleſs this Definition was afterwards Advanced into a Law of Nature, which is done Law the Firſt, which ſays, that every Body perſiſts in it's State of Reſt, or of Motion *in Directum*, unleſs it is forced from that State by an External Impreſſion; To Prove this Propoſition likewiſe it was neceſſary to Introduce *Corol.* 1. of the Laws, that a Body Deſcribes with it's Joint Forces the Diagonal of a Parallelogram in the ſame Time, in which the Sides of it are Deſcribed by the Separate Forces; Nor yet was this ſufficient to Evince the Preſent Propoſition, excepting Corollary the 4*th* Lemma 3*d* of the *Method* of *Naſcent* and *Evaneſcent Reaſons* was Allowed, which Lemma we have already Conſidered.

From this one ſuppoſed Phænomenon therefore of the Planets Deſcribing Areas Proportional to the Times of their Deſcription, which is *Kepler's* Aſſertion, is Derived this whole Philoſophy; and this Firſt Propoſition is Proved by ſo many Aſſumed Definitions, Laws, and Lemmas, none of which, as we have ſhewn, are Evinced, that it would give any Rational Man a Diſtaſte and a Thorow Averſion to it. But, which is more, the Definitions, the Laws, and Lemmas of this Philoſophy are Originally made and Contrived from this Propoſition, and then are uſed to Prove it.

Sir Iſ. Newt. Princ. Prop. 4. Lib. 1. Corol. 6. & Schol.

The Definitions of Names being thus Eſtabliſhed into Things and Realities, the Laws Allowed, and the Lemmas in a Certain way Demonſtrated, all which were neceſſary to Confirm the Preſent Propoſition, it was eaſy from thence to Proceed to the 4*th* Propoſition, and the 6*th* Corollary of it; but, how that is made to Appear, I have already Declared, and which is nothing more than a Reaſoning Accommodated to what Sir *Chriſtopher Wren*, Dr. *Hooke*, and Dr. *Halley* had Embraced, which is Equally Wrong and Proceeds upon the ſame Unjuſtifiable Abſtractions; which ſhews the Artifice of this Philoſophy, that it does not ſo much Proceed upon the Reaſon of Things, as caſts about and Conſiders, how it may ſuit it ſelf to the Acknowledgments and Confeſſions of the Greateſt and moſt Celebrated Men in theſe Studies.

For we have Evidently Evinced, that this Sixth Corollary and the Propoſition, from which it is Derived, is Falſe in Reaſon, and therefore cannot be Applicable to any Motions in Nature. The Corollary is, That, if the Periodical Times are in a Seſquiplicate Reaſon of the Diſtances, the Centripetal Forces will be Reciprocally, as the Squares of thoſe Diſtances, which this Philoſophy finding to Agree with what *Hugens* had pretended to Demonſtrate in Reſpect of the Centrifugal Forces, and with what Sir *Chriſtopher Wren*, Dr. *Hooke*, and Dr. *Halley* had done, all was Certain and Sure, as to that Point, and it had nothing more to Endeavour than the Third Thing, which was to ſhow, that this Reaſoning of the Mechanical Philoſophers exactly Correſponded with the Revolutions of the Planets in Ellipſes, by which it would at once oblige Aſtronomy, as it was Propoſed by *Kepler* and his Followers, and the Mechanical Doctrine, as it was Propoſed by *Hugens*.

Dr. Keill's Intr. ad Ver. Phyſicam. De vi Centrifugâ & Motu Circulari.

This being the main Intention and Deſign to Reconcile the Mechanical Philoſophy, with the Aſtronomy and Obſervations of *Kepler*, the next Step, which was made, was to Prove, ſince *Kepler* Affirms that the Planets are Revolved in Ellipſes, and the Mechanical Philoſophers Affirm, that if the Periodical Times are in a Seſquiplicate Reaſon of the Diſtances, the Centripetal Forces are Reciprocally, as the Squares of ſuch Diſtances, that Bodies Revolved in Ellipſes obſerve that Reciprocal Duplicate Proportion.

Third, And from hence this Philoſophy is Carry'd to Propoſition the 11th, §. 3. *Lib.* 1. that is, to Inquire into the Law of the Centripetal Force, by which a Body Revolves in an Ellipſis round the Focus or Umbilicus of it, which, by Lemmas or Aſſumptions not ſufficiently Proved, and by Compounding of Reaſons at Pleaſure, and other Arbitrary Methods, at length Concludes, what was before-hand Deſigned, that the Centripetal Force is Reciprocally, as the Square of the Diſtance.

Sir Iſ. Newt. Princip. Prop. 11. Lib. 1.

And this is the Occaſion of *Prop.* 6th, 7th, 8th, 9th, and 10th, being Premiſed to it, whereas this Propoſition was the Firſt in View, and when there were ſeveral Things neceſſary to Clear it, thoſe Things were built into Independent Propoſitions of themſelves, as if they had no Relation to any Thing; Albeit they were Originally Contrived and Invented, as the Laws and Definitions before, to ſerve one End and Purpoſe, which in the Preſent Caſe was that of making the Centripetal Force in the Ellipſis Reciprocally, as the Squares of the Diſtances; and with this Intent the 6th Propoſition in Particular was Apparently Introduced, and which, as well as the 11th, we have at Large Conſidered and Examined, and could eaſily do the other Intermediate ones, if it was worth the Time or the Trouble; but it would be an unneceſſary Expence of both after what we have ſaid; and we ſhall only obſerve, that, in General, in this Philoſophy the Firſt Things in it were the Laſt Thought of, and the Laſt Firſt, as may be Evidenced in every Part of this Syſtem.

Sir Iſ. Newt. Princip. Prop. 6, 7, 8, 9, & 10. Lib. 1.

Fourth, From theſe Thoughts and Notions, and when the Mind was Warmed with them, it was Natural to Proceed to an Inquiry into the Law of the Centripetal Force Tending to the Umbilicus of an Hyperbola, ſuppoſing a Body Moved in it, or what the Law of the ſaid Centripetal Force Tending to the Umbilicus of a Parabola would be, ſuppoſing a Body was Moved in that Figure. This brought the Preſent Philoſophy into a Train of Ideas and Reaſoning concerning the *Conick Sections* for many Propoſitions together to §. 7. *Lib.* 1. which ſhews the Great and Wonderful Art and Skill of the Geometer in Manageing of Proportions and Quantities, but ſeems to be of little Uſe or Advantage to the Knowledge of Nature.

Sir Iſ. Newt. Princip. Prop. 12. Lem. 13, 14. Prop. 13. to §. 7. Lib. 1.

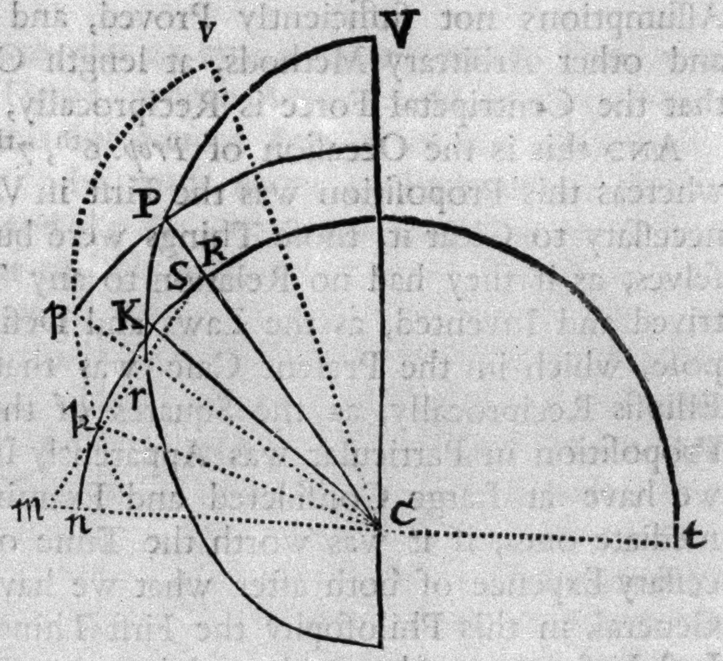
Fifth, Sect. 7th. is concerning the Rectilineal Aſcent and Deſcent of Bodies, and ſuppoſing the Centripetal Force is Reciprocally Proportional to the Square of the Diſtance of the Places from the Center, to Determine the Spaces, which a Body Deſcribes in any Given Times by a Perpendicular Deſcent. The 8th is Concerning the Invention of Orbits, in which Bodies are Revolved, when Acted by any Centripetal Forces whatſoever, till at Length we come to §. 9. which gives an Account of the Motion of the Apſides, which we ſhall now Conſider.

Sir Iſ. Newt. Princip. §. 7, & 8. Lib. 1.

THIS is a ſhort Explanation of the Riſe, Beginnings, and Structure of the Preſent Phyſical Aſtronomy, in which there will upon a ſtrict Examination be found to be more Artifice and Contrivance than Truth, more Quickneſs and Skill in Geometry than Exactneſs in Reaſoning, and more Poſtulatums and Aſſumptions and Arbitrary Abſtractions, than Real Laws of Nature, and Theorems of Philoſophy; It muſt be Confeſs'd, that this Reaſoning has one Advantage on it's Side, ſince it is about Beings ſo Remote from us, that, if an Hypotheſis is pretty well laid together, it will be the Harder to Confute it, becauſe we know not, what the Circumſtances and Conditions of thoſe Beings are, and therefore muſt take them, as they are Explained, unleſs we can ſhew a Falſity in the Hypotheſis it ſelf; in which it Agrees with the Corpuſcular Philoſophy, which by it's Infinitely ſmall Particles puts it out of our Power of Demonſtrating the Abſurdity of it by our Senſes; For thus the Phyſical Aſtronomy Relates to Bodies, which are ſo Infinitely Removed from our Inſpection, that we muſt Deſpair of Confuting it's Arguments by Pointing to and Shewing the Bodies themſelves; But as from Reaſon we have Evinced the Extreme Folly of ſuch Infinitely ſmall Particles Exiſting in Nature, as the Conſtituents of Bodies, in like Manner we may by Inquiring into the *Rationale* of this Aſtronomy, make it Evident, that all this *Apparatus* of Lines and Angles, of the *Vis Inſita*, and the Centripetal Force, is nothing, but mere Pageantry, and has no Subſiſtence or Being in Reality.

Concerning the Motion of a Body in a Moving or a Quieſcent Trajectory. Sir If. Newt. Princip. Prop. 43. §. 9. Lib. 1. Dr. Gregory's Aſtronom. Prop. 3. §. 2. Lib. 4.

§. 14. THE next Propoſition therefore which we ſhall Examine is that, which is to Inform us, how a Body may be alike Moved in any Trajectory Revolving about a Center of Forces, as another Body in a Trajectory, which is Quieſcent. In the Orbit VPK, which is Given in it's Poſition, Let a Body P be Revolved from V towards K, from the Center C Let Cp be always Drawn Equal to CP, and form an Angle VCp Proportional to the Angle VCP; The Area, which the Line Cp Deſcribes, will be to VCP the Area, which the Line CP Deſcribes at the ſame Time, as the Velocity of the Deſcribing Line Cp to the Velocity of the Deſcribing Line CP, that is, as the Angle VCp to the Angle VCP, namely, in a Given Reaſon, and therefore Proportional to the Time; Since then the Area, which the Line Cp Deſcribes in an Immoveable Plane is Proportional to the Time, it is Evident, that the Body, by ſome Determinate Centripetal Force Urging it, may be Revolved together with the Point p in that Curve Line, which the ſame Point p in the Reaſon Explained Deſcribes in an Immoveable Plane; Let the Angle VCv be made Equal to the Angle PCp, and the Line Cv to the Line CV, and the Figure vCp to the Figure VCP, and the Body, being always in p, will be Moved in the Perimeter of the Revolving Figure vCp, and will Deſcribe an Arc of it vp in the ſame Time, in which another Body P Deſcribes an Arc VP Similar and Equal to it in the Quieſcent Figure VPK: Let therefore the Centripetal Force be Inquired by *Corol.* 5. *Prop.* 6, by which a Body may be Revolved in that Curve Line, which the Point p Deſcribes in an Immoveable Plane, and the Problem is Solved. *Q. E. F.*



BUT let theſe Philoſophers give me leave to Anſwer, FIRST, That a Body Deſcribing an Area Proportional to the Time is Demonſtrated upon the Suppoſition of an Immoveable Plane, of a *Vis Inſita* or a Projectile Force Proceeding in a Tangent, and of a Centripetal one, by *Prop.* 1, of this Philoſophy; and conſequently, if Cp in the Moveable Plane pCv Deſcribes Areas Proportional to the Times, it will be neceſſary to ſhow us, how a Moveable Plane is the ſame as an Immoveable one, and where and what is the Projectile Force in this Caſe, which Acts in a Right Line or a Tangent, and then we ſhall acknowledge or not, that there is a Centripetal

Force too of one Kind or other, by which the Figure Deſcribed by p in the Moveable Plane vCp is Performed.

SECOND, Suppoſing Cp to be Drawn always Equal to CP, and p to be in the Moving Orbit at the ſame Diſtance from v, as P from V in the Quieſcent one, that is, that p in the one Caſe Moves exactly as P in the other, excepting that vCp is Revolved about C, whilſt VCP is an Immoveable Plane, by which the Difference of the Motions p and P will be Conferred upon VCv, or which is the ſame, upon vC Departing from VC; It is not yet Evident, how VCp will be an Angle Proportional to VCP; Becauſe, tho' Cp and CP from V and v will Deſcribe Areas Proportional to the Times, ſuppoſing VCP and vCp to be Quieſcent Planes, according to this Philoſophy, and tho' VC in it's Progreſs to vC will, according to the ſame Philoſophy, Deſcribe Areas Proportional to the Times, ſuppoſing the ſaid Planes to be Moveable ones, yet it will not follow, that Cp Deſcribes Areas Proportional to the Times, when the Plane vCp is Moveable, ſince the Body p will not have the ſame Effect, either in it's Projectile or Gravitating Force, when the Plane vCp is Revolved round C, as the Body P has, when VCP is Quieſcent, and therefore will not Deſcribe Areas Proportional to the Times in the Moveable Plane, if P does in the Quieſcent one; for we are not to Conſider p Revolving in vp in the ſame Manner, as P in VP, and make all the Difference of their Revolutions to lie in Cv being Carry'd in an Angular Motion from CV; which, notwithſtanding, is the Senſe of this Propoſition, and which therefore takes for Granted, what is to be Proved, that p Deſcribes Areas Proportional to the Times in a Moving Plane, becauſe P does in a Quieſcent one.

THIRD, Suppoſing p did Deſcribe Areas Proportional to the Times, yet ſince it does it under Different Circumſtances, than what were before Alledged in Propoſition the 1*ſt* of this Philoſophy, when Figures were made by a Projectile and a Gravitating Force, it would not Enſue, that p likewiſe was Revolved by ſuch Forces, ſeeing the Projectile Force it ſelf is here a Circular one, which before was ſuppoſed always to Act in a Tangent.

FROM whence we may Conclude, that here is a new Aſſumption made in the Preſent Philoſophy, and which is no otherwiſe Proved than by the Neceſſity of it to it's Future Explications.

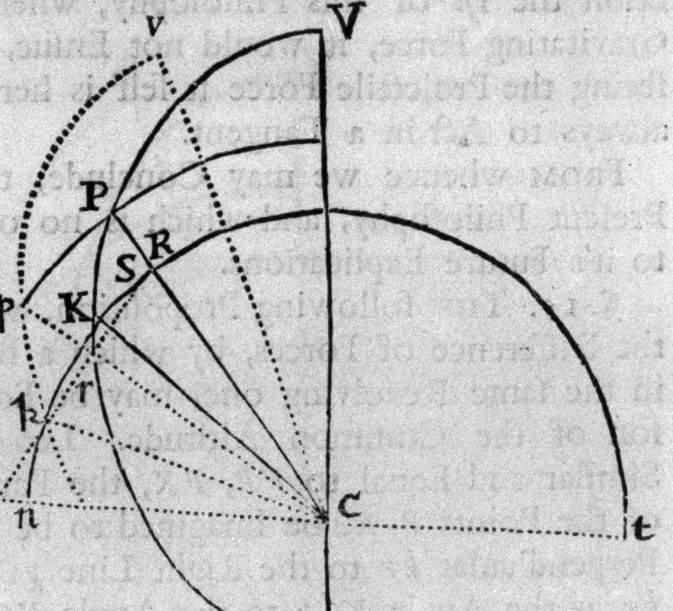
Concerning the Difference of the Forces, by which a Body is Moved in a Quieſcent or Revolving Trajectory.
Sir Iſ. Newt. Princip. §. 9. Prop. 44. Lib. 1.
Dr. Gregory's Aſtronom. §. 2. Prop. 4. Lib. 4.

§. 15. THE following Propoſition, which we ſhall likewiſe Examine into, is, that the Difference of Forces, by which a Body in a Quieſcent Orbit, and another Body in the ſame Revolving one, may be Equally Moved, is Inverſely in a Triplicate Reaſon of the Common Altitude. Let vp, pk the Parts of a Revolving Orbit be Similar and Equal to VP, PK, the Parts of a Quieſcent one, and let the Diſtance of the Points P, K, be Imagined to be Infinitely ſmall; From the Point k Draw the Perpendicular kr to the Right Line pC, and Produce it to m, ſo that mr may be to kr as the Angle VCp to the Angle VCP; and ſince the Altitudes of the Bodies PC, and pC, KC and kC are always Equal, it is Evident, that the Increments or Decrements of the Lines PC and pC are always Equal; and therefore, if each of the Motions of the Bodies, when they are in P and p, are Diſtinguiſhed into Two, by *Corol.* 2, of the Laws, the one of which is Determined towards the Center, or according to the Direction of the Lines PC and pC, and the other is Tranſverſe to the Former, and according to Lines Perpendicular to PC and pC, the Motions towards the Center will be Equal, and the Tranſverſe Motion of the Body p will be to the Tranſverſe Motion of the Body P, as the Angular Motion of the Line pC to the Angular Motion of the Line PC, that is, as the Angle VCp to the Angle VCP; Conſequently in the ſame Time, in which the Body P with both it's Motions Arrives at the Point K, the Body p with an Equal Motion towards the Center will be Equally Moved from p towards C, and upon the Determination and Concluſion of that Time will be found ſomewhere in the Line mkr, which Drawn thro' the Point k is Perpendicular to pC, and will by it's Tranſverſe Motion acquire a Diſtance from the Line pC, which will be to the Diſtance, which the other Body P acquires from PC, as the Tranſverſe Motion of the Body p to the Tranſverſe Motion of the Body P, that is, as the Angle vCP to the Angle VCP, or as mr to kr, and therefore the Body p at the End of ſuch Time will be found in m; Theſe Things will be ſo, when the Bodies p and P are Moved Equally according to the Lines pC, and PC, and conſequently are Urged by Equal Forces according to thoſe Lines; Let now the Angle pCn be to the Angle pCk, as the Angle VCp to the Angle VCP, and let nC be Equal to kC, and the Body p at the End of the ſame Time will be found in n, and ſo is Urged by a Greater Force than the Body P, if the Angle mCp is Greater than the Angle kCp, that is, if the Trajectory or Orbit vpk is Moved *in Conſequentia*, or if it is Moved *in Antecedentia* with a Greater Celerity, than the Double of that, with which the Line CP is carry'd *in Conſequentia*; and by a Leſs Force, if the Orbit is Moved Slower *in Antecedentia*; and the Difference of the Forces will be, as the Interval of the Places mn thro' which the Body p is Transferred by it's Action, in the aforeſaid Time. From the Center C with the Radius Cn or Ck, Let a Circle be Deſcribed, ſo as to Interſect the Lines mr, mn Produced, in s and t, and the Rectangle $mn \times mt$ will be $= mk \times ms$, by the *Elements* of *Euclid*, and $mn = \frac{mk \times ms}{mt}$; and ſince the Triangles pCk, pCn are given in their Magnitude, kr and mr, and their Difference mk, and their Sum ms are Reciprocally, as the Altitude pC; and therefore the Rectangle $mk \times ms$ is Reciprocally, as the Square of the Altitude pC; Alſo mt is Directly as $\frac{1}{2}\,mt$, that is, as the Altitude pC, and conſequently the Naſcent Line $mn = \frac{mk \times ms}{mt}$ is Reciprocally, as the Cube of the Altitude pC. *Q. E. D.*

Dr. Gregory's Aſtronom. Prop. 4. Corol. 1. Lib. 4.

The Objections which lie againſt the Foregoing Demonſtration.

§. 16. But notwithſtanding the Authority of the Propoſer, and the Capital Letters Affixt to Show us, or to Perſwade us, that the Propoſition is ſtrictly Proved, we muſt beg the Liberty to Inquire, whether it is ſo or not.



And First, PK and pk being ſuppoſed Infinitely Small, all which has been Objected againſt the Method of Naſcent and Evaneſcent Reaſons will have a Place here.

Second, Since $mr \,.\, kr :: VCp \,.\, VCP$, upon which Proportion this whole Reaſoning Proceeds, that is likewiſe taken for Granted, which we have Diſproved in the foregoing Propoſition, namely, that the Centripetal Force of the Body p in the Revolving Trajectory is the ſame, as that of P in the Quieſcent one, ſince the Tranſverſe or Projectile Force will make an Alteration in the one, which is not from the Quieſcence of the Orbit Induced upon the other; and therefore, tho' pC and PC, kC and KC are Equal, the Increments and Decrements of thoſe Lines will not be ſo.

Third, The Diſtinguiſhing the Motion of each Body P and p into Two by *Corol.* 2 of the Laws has been Examined, and the Reaſoning Refuted.

Fourth, Granting which, the Forces, into which the Motion of each Body P and p is Reſolved, are not Juſtly and Truly Aſcertained, ſince in the Quieſcent Trajectory, the Forces, with which P Revolves, are Confeſſed to be a Centripetal to C, and a Projectile one in a Tangent according to the foregoing Propoſitions in this Philoſophy, whereas here, in order to make them Correſpond with the Compound Forces of p, thoſe of P are Affirm'd to Conſiſt of a Centripetal to C, and a Tranſverſe, Perpendicular to PC, and which is Meaſured by the Angle VCP, Deſcribed by the Angular Motion of the Line PC, which is very Different from the *Vis Inſita* Acting in a Tangent, becauſe this Tranſverſe Motion it ſelf, being an Angular one, is made up of a Centripetal and a Projectile by this Philoſophy, and therefore cannot be ſubſtituted in the Room of a Simple Projectile; Nor is it ſufficient to ſay, tho' here ſeems to lie the Fallacy, that the Tranſverſe Motion is ſuppoſed to be Perpendicular to PC, as the Projectile is, and therefore the one may be Aſſumed for the other, this is not ſufficient; Becauſe a *Vis Inſita*, Proceeding Equably in a Tangent, can never be Reduced to, or Expreſſed by an Angular Motion, which Conſiſts of that, and a Centripetal one; Beſides, ſince the Areas VCP are Proportional to the Times of their Deſcription, the Angular Motion of CP from VC will be very Unequal, and therefore an Improper Repreſentative of the *Vis Inſita*, which goes on uniformly.

FARTHER, Which ſhews this Philoſophy do's Juſt what it Pleaſes, Allowing what has been before Diſputed, the Right Line, which is Perpendicular to PC, does not ſo much as Exhibit this Tranſverſe or Angular Motion, no more than the Sine of any Angle is the Expreſſion of the Angle, that is, the Perpendiculars to PC are not Proportional to the Angles VCP, or to the Elongations of PC from VC. In the Moving Trajectory all theſe Things are ſtill more Embarraſſed and Confuſed, for in this Caſe the Tranſverſe Motion is ſaid to be as the Angular of pC, or as the Angle VCp, againſt which not only all, which has been before Alledged, is Valid, but more, It is altogether Unaccountable, how a Perpendicular to pC, which would Repreſent the Tranſverſe Motion according to this Propoſition, if the Trajectory was Quieſcent, ſhould be made uſe of to Explain the Tranſverſe Motion, when the Trajectory is ſuppoſed to be a Revolving one, and how mk, which is in the ſame Direction with kr ſhould Exhibit or Expreſs the Tranſverſe Motion of VCv, that is, of a Line, which is Parallel to mC, and Inclined in an Angle to mk; or it is Inconceivable, as well as not Proved, that $mr.kr::VCp.VCP$, or as the Tranſverſe Motion of the Body p, to the Tranſverſe Motion of the Body P, ſince the Tranſverſe Motion of the Body p cannot be Reſembled to the Angular one of pC from VC, which Conſiſts of Cp from Cv, and of Cv from CV at the ſame Time, but the Angular Motion vCp is Compounded of a Centripetal and Projectile Force, which therefore cannot be Expreſſed by a Projectile, or a Line Perpendicular to pC, and the Angular Motion VCv is Compounded likewiſe of a Centripetal and a Projectile, which has a Different Direction from the Former, being Parallel to Cm, and therefore cannot alſo be Expreſſed by the ſame Perpendicular to pC, and conſequently it is not Evinced, that the Body p will be found in m.

MOREOVER, if $mr.kr::VCp.VCP$, mr muſt be Evidently Greater than kr, and therefore the Tranſverſe Force mr will Carry p out of it's Elliptical Orbit from k to m, the Centripetal Forces being Equal; if ſo, and the Tranſverſe Force is Superior to the Centripetal, it cannot be ſhewn, why the ſame Tranſverſe Force ſhould not Carry the Body forward in the ſame Right Line, without permitting it to Revolve in an Ellipſis, or any other Curve whatſoever; unleſs it can be ſuppoſed, that the Centripetal Force has a Greater Power to Recollect it ſelf in m towards C, than it had in k, when it was nearer to it; If yet this was not Effected by the Superiority of the Tranſverſe Force, the Ellipſis or Trajectory notwithſtanding would be Spoiled, whereas this Propoſition is Contrived to ſhew us, how and with what Forces a Body may be Moved in a Revolving Ellipſis or Trajectory.

FIFTH, One would think here were Poſtulatums and Aſſumptions ſufficient already to give an Inquirer enough of the Preſent Demonſtration, and yet it has not done Asking; the Body p is brought one way or other to the Point m, but this would ſignify nothing, if there was no Difference in the Centripetal Forces, which have hitherto been Imagined to be the ſame in p and P; in order therefore to make this Difference, it is Preſcribed, that the Angle pCn ſhould be made to pCk, as the Angle VCp to the Angle VCP, and that the Line nC ſhould be Equal to kC, and ſo the Body p will be found in n, and therefore is Urged with a Greater Centripetal Force than the Body P, if the Angle mCp is Greater than the Angle kCp, that is, if the Orbit vpk is Moved *in Conſequentia*, and the Difference of the Forces will be mn.

BUT here alſo it is to be obſerved, that VCP, VCp are ſtill the Meaſure and Standard of the Tranſverſe Forces, which has been already Objected againſt, Granting which, it is now Affirmed, that $pCn.pCk::VCp.VCP$, and before $::mr.kr$, ſince therefore nkr may be as juſtly the Meaſure of pCn or pCm, as mkr, mk will be Equal to nk, and m and n will Coincide, and we are got no farther than we were at our Firſt ſetting out in this Demonſtration. Beſides which, nC is made Equal to kC, that the Body p may be at the ſame Diſtance from C in n, as in k, and yet without any Apparent Cauſe, the Centripetal Force in n is made Greater than in k, and no wonder, becauſe the Body p is as Arbitrarily Removed from m to n, as that Greater Centripetal Force is Arbitrarily Introduced; For if the Diſtances from C in k and n are Equal, what ſhould make the Body p Gravitate more in n than in k? If it is ſaid, That is Neceſſary to bring it from m (whither the Tranſverſe Force would have carry'd it) to n, the Neceſſity is Acknowledged, but from whence p ſhould have a Greater Centripetal Force at m, ſo as to Determine it to n, is the Inquiry, eſpecially when the Tranſverſe Force has already Carry'd p out of it's Orbit to m.

Farther, Suppoſing the Body p in n, it is yet out of the Moving Ellipſis or Trajectory, whereas this Propoſition was to give an Account of the Forces neceſſary to keep a Body within ſuch a Moving Ellipſis or Trajectory, and is accordingly apply'd in all the Subſequent Philoſophy.

Sixth, Having at Length with a great Deal of Labour, and with no Small Satiſfaction to it ſelf, tho' with little to any Impartial Conſiderer, Settled the Difference of Forces, which is Propoſed to be mn, this Demonſtration Proceeds by the *Elements* of *Geometry* to Aſcertain, what this Force muſt be; A Circle therefore is Drawn by the Radius nC, or kC, the Secants of which are mt, ms, and the Lines Intercepted betwixt the Point m and the Circle, are mn, mk, and therefore, by the ſaid *Elements*, $mn \times mt$ is Equal to $mk \times ms$, and $mn = \frac{mk \times ms}{mt}$, which, by what I can Perceive, is the only certain Thing in the whole Proceſs of the Preſent Reaſoning. But then, when it goes on again upon it's own Principles and Aſſumptions, we are Loſt and Bewilder'd as before, and find Nothing, which is Clear or Concluſive.

Thus the Triangles pCk, pCn are ſaid to be Given in their Magnitude, but wherefore? Becauſe the Angles pCk, pCn are as VCP to VCp, which has been already Conſidered; But ſuppoſing they are ſo, it does not follow, that kr and mr are Reciprocally, as the Altitude pC, ſince in the Triangle pCn, mr has nothing to do, unleſs mr and nr are the ſame, and then mn or the Difference of the Forces is Nothing; If therefore kr and mr are not Reciprocally, as the Altitude pC, their Difference mk, and their Sum ms, are not in that Reciprocal Proportion of the Altitude pC, nor the Rectangle $mk \times ms$ Reciprocally, as the Square of ſuch Altitude.

To make mn this Imaginary Difference of Equal Forces to be Reciprocally, as the Cube of the Altitude pC, it is farther Aſſumed, that mt or $\frac{1}{2}mt$ is in a Direct Proportion, as the Altitude pC, which is Impoſſible, ſince, if $pCk . pCn :: kr . mr$, m will be Determined by that Proportion, and which Determination of m will be ſo Uncertain, that neither mC, nor mt, nor $\frac{1}{2}mt$ will be Directly as pC, and conſequently, $\frac{mk \times ms}{mt}$ will not be Reciprocally, as the Cube of the Altitude pC, and yet this was the Propoſition to be Demonſtrated.

The Corollaries not neceſſary to be Conſider'd, nor the following Propoſitions of this Section.
Sir Iſ. Newt. Princip. Prop. 44. & Corol. & Prop. 45. Corol. Lib. 1. Dr. Gregory's Aſtronom. Prop. 4. Lib. 4. Corol Prop. 5, 6, 7, & Corol.

§. 17. After this Point was Confirmed, this Philoſophy had Room to Play and Divert it ſelf with Quantities and Proportions from *Corol.* the *1ſt* to the *6th*, which Concludes this Propoſition, and from thence Proceeds to *Prop.* the *45th*, and it's Two Corollaries; None of which there is any Occaſion to Examine, unleſs becauſe it Introduces it's Fluxions here, which we ſhall afterwards Conſider, and thus Ends Section the Ninth.

The Doctrine of the Revolution of the Apſides farther Explained.

§. 18. And now we are able to give a more Particular Account of the Doctrine of the Revolution of the Apſides in this Philoſophy, which we before Promiſed, and could not ſo well Explain, till we had made an Examination into the foregoing Propoſitions; For the Direct Conſequence, which follows from the Preceding Demonſtration, and upon which the Doctrine of the Revolution of the Apſides Depends, is, That if from a Centripetal Force, which is Reciprocally, as the Square of the Altitude, a Force be Subſtracted, which is Directly as the Altitude, a Force Remains, which in it's Receſs from the Center Decreaſes more, or is Leſs than according to a Duplicate Reaſon of the Altitude Increaſed, or which in it's Acceſs to the Center Increaſes more, or is Greater than according to a Duplicate Reaſon of the Altitude Diminiſhed; in both which Caſes, the Apſides will be Progreſſive, or be Carry'd *in Conſequentia*; On the Contrary, if to a Centripetal Force, which is Reciprocally, as the Square of the Altitude, be added a Force, which is Directly as the Altitude, a

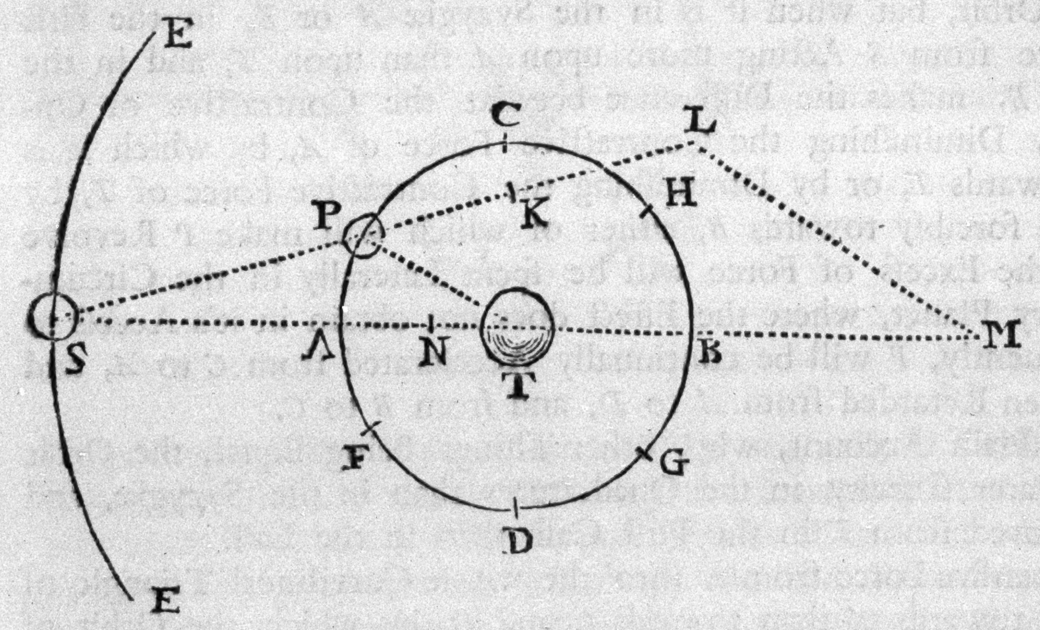
Force is Compounded, which in it's Receſs from the Center Decreaſes Leſs, or is Greater than according to a Duplicate Reaſon of the Altitude Increaſed, or which in it's Acceſs to the Center Increaſes Leſs, or is Leſs than according to the Duplicate Reaſon of the Altitude Diminiſhed; in both which Caſes, the Apſides will be Regreſſive or be Revolved *in Antecedentia*; If now this be Apply'd, which is Deduced from the Demonſtration Premiſed, and particularly from that, which is Alledged in the Middle of it, Concerning the Orbit being Carry'd *in Conſequentia* or *in Antecedentia*, as the Centripetal Force is Greater or Leſs than in a Duplicate Proportion, If this be Apply'd to what we have before Produced concerning the Apſides in the Corollaries to the *66th* Propoſition of this Philoſophy, which we have already Examined, the Whole of this Doctrine will be fully Explained; and as we have ſhewn this Demonſtration to be Precarious and Inconcluſive upon ſeveral Accounts, it follows, that this Doctrine of the Revolution of the Apſides ſubſiſts in the Fancy and Imagination only, and has Nothing to ſupport it, but Lines and Figures, Arbitrary Aſſumptions, and Poſtulatums, which cannot be Granted, and therefore is deſervedly Rejected by us.

An Explanation of the Phænomenons of the Primary and Secondary Planets from the Expanſive and Contractive Forces.

§. 19. WE ſhall now therefore Endeavour to give an Explanation of theſe Phænomenons of the Primary and Secondary Planets from the Expanſive and Contractive Forces, and ſhall take them in the ſame Order, as they are Propoſed to us *Prop. 66. Lib.* 1. of this Philoſophy.

Sir Iſ. Newt. Princip. Prop. 66. Corol. 2, 3. Lib. 1. Dr. Gregory's Aſtronom. Prop. 1. Lib. 4.

1*ſt*. IN a Syſtem of Three Bodies *T*, *P*, and *S*, the Laſt of which has an Expanſive Force, as the Sun, by which it Repells all Bodies from it, and the other Two a Contractive, by which they Draw all Bodies towards them, as the Earth and Moon, or a Primary and Secondary Planet, or Two Primary, or Two Secondary ones, for the Caſe is much the ſame, when we Conſider them as Endued with the like Contractive Forces, Let us therefore take the Firſt Inſtance of a Primary and Secondary Planet, namely of the Earth and the Moon, ſince the Reſt may be Reduced to it with Certain Allowances, There ſeem to be Two Reaſons, wherefore the Secondary Planet *P* in it's Orbit round the Primary *T*, is Accelerated from *C* to *A*, Retarded from *A* to *D*, and again Accelerated from *D* to *B*, and again Retarded from *B* to *C*, and conſequently, why the Secondary Planet *P* Moves with a Greater Velocity in the Syzygiæ *A* and *B*, than in the Quadratures *C* and *D*, other Things being Equal.



FIRST, Becauſe, the Expanſive or Repulſive Force of the Sun Spreading and Diffuſing it ſelf from *S* thro' the whole Triangle *CST*, *P*, when in *C*, has all that Force to Surmount in it's Deſcent towards *A*, and therefore Moves with a Leſs Velocity in *C*, where the Expanſive Force of the Sun Acts very near Equally upon the Primary Planet in *T*, and on the Secondary in *C*, but when the Secondary Planet Arrives at *P*, it has a Leſs Expanſive or Repulſive Force Acting in the Triangle *PSA* to Subdue, by which means it Moves with a Greater Velocity continually in it's Deſcent from *C* to *P*, and from thence to *A*.

IN it's Aſcent from *A*, it has all the Expanſive Force *TSD*, which Acts from *S*, Tending the ſame way with it's own Motion, and therefore is Accelerated in *A*, but Leſs in *F*, becauſe the Triangle *FSD* of the Expanſive or Repulſive Force is Leſs, from whence it is ſtill Leſs Accelerated in it's Paſſage from *F* to *D*.

LIKEWISE from *D* to *B* it is again Accelerated, yet Leſs in *D*, becauſe in the Triangle *TSD* the Expanſive Forces from *S* are nearly Equal in *T* and *D*, but More in *G*, becauſe the Expanſive Forces *GSD*, which Tend the ſame way, are Greater, and the

Moſt in *B*, becauſe the Expanſive Forces *BSD*, Tending the ſame way, are then the Greateſt.

AGAIN in it's Paſſage from *B* to *C* it is Retarded by the Expanſive Force Acting Contrary to it, in *B* Leſs, in *H* More, becauſe *HSB* is Greater than *SB*, and in *C* the Moſt, becauſe the Expanſive Forces in the Triangle *CSB* Acting Contrary ways are then the Greateſt; All this is ſaid upon the Suppoſition, that, of it ſelf, *P* Revolves about *T* uniformly by Certain Forces Adjuſted betwixt them, which are not here Conſidered.

SECOND, Another Reaſon of this Acceleration and Retardation in the Syzygiæ and Quadratures is, That in the Firſt Caſe the Contractive Forces are Diminiſhed, in Reſpect of each to the other, and in the Laſt not ſo. To Explain this more Particularly; Thus *P* Revolves about *T* by that Exceſs of the Contractive Force, which the one has above the other, whether of *T* above *P*, or of *P* above *T*, for ſince that Exceſs of Force, by which they Draw againſt, and in Oppoſition to each other, cannot bring them Together, it muſt of Neceſſity be ſpent Sideways, and by that means occaſion a Revolution; the Greater ſuch Exceſs therefore is, the Quicker will the Revolution be, and the Leſs ſuch Exceſs is, the Slower; For by this very Method it is, that a Stone Revolves in a Sling, the Hand Attracting the String one way, and the Stone another, the Exceſs of which Two Forces is conferred upon the Circular Motion Produced from the Conteſt between them; This does not obtain in Two Forces Drawing againſt each other, and Gravitating to a Third as the Earth, becauſe ſuch Gravitation hinders the Revolution, which, as it is an Argument, that the Earth and Moon and the other Planets do not Gravitate to the Sun, ſo it is a Reaſon, why any Sublunary Forces cannot be Objected againſt this Doctrine.

FROM whence it comes to paſs, that, when the Secondary Planet is in the Quadratures *C* or *D*, the Expanſive Force from *S* Acting nearly alike upon both, it Proceeds uniformly in it's Orbit, but when it is in the Syzygiæ *A* or *B*, in the Firſt Caſe the Expanſive Force from *S* Acting more upon *A* than upon *T*, and in the Laſt upon *T* than upon *B*, makes the Difference betwixt the Contractive or Oppoſite Forces Greater, by Diminiſhing the Contractive Force of *A*, by which it is Drawn more forcibly towards *T*, or by Diminiſhing the Contractive Force of *T*, by which it is Drawn more forcibly towards *B*, either of which will make *P* Revolve Faſter about *T*, becauſe the Exceſs of Force will be ſpent Laterally in the Circumvolution of the Secondary Planet, where the Effect does not obtain in it's Acceſs to the Primary, and conſequently, *P* will be continually Accelerated from *C* to *A*, and from *D* to *B*, and as often Retarded from *A* to *D*, and from *B* to *C*.

Sir Iſ. Newt. Princip. Prop. 66. Corol. 4, 5. Lib. 1. Dr. Gregory's Aſtronom. Prop. 2. Lib. 4.

2*d*. FROM hence is a Plain Account, why, other Things being Equal, the Orbit of the Body *P* has a Greater Curvity in the Quadratures than in the Syzygiæ, and therefore is farther Removed from *T* in the Firſt Caſe than in the Laſt.

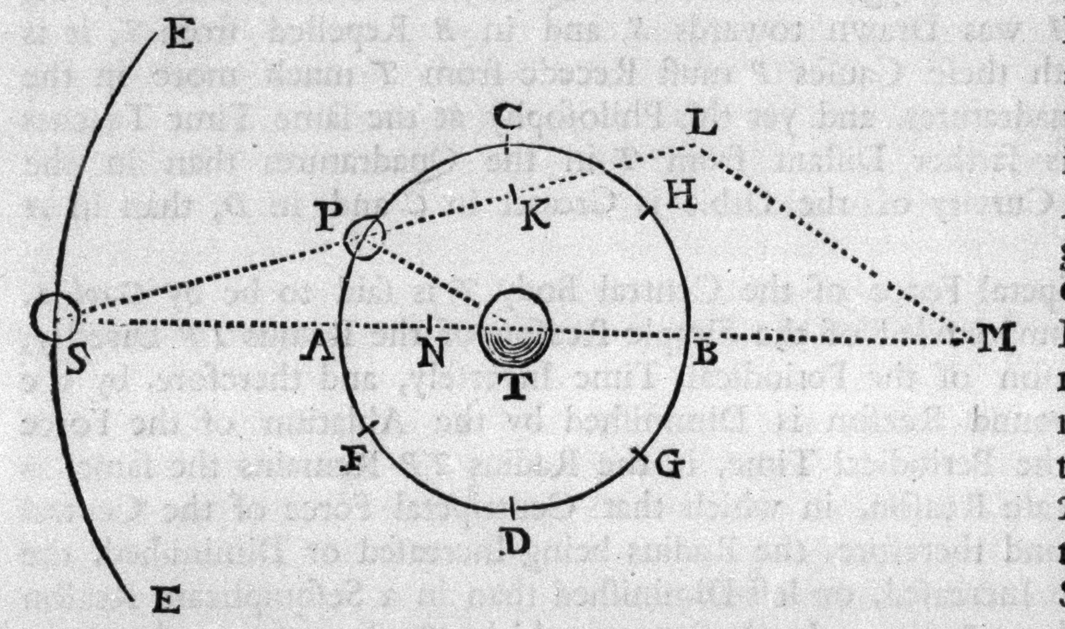
FIRST, Becauſe the Expanſive Force from *S*, thro' the whole Curvilineal Triangle of it *CSDAC*, is Stronger towards *A* than towards *C* and *D*, by which the Orbit of *P* is Flattened and Depreſſed in *PAF*, and made more Prominent in the Quadratures; ſo likewiſe in the Curvilineal Triangle *CSDBC*, *CBD* is Depreſſed towards *T*, becauſe the Expanſive Force from *S* Acts Stronger in *C* and *D*, and the Parts Adjoining, than in *HBG*, which therefore Sinks nearer to *T*, or the Secondary Planet *P*, which Deſcribes the Orbit, Approaches to *T*, which is the ſame.

SECOND, Becauſe the Expanſive Force from *S* Deſtroys ſome of the Contractive Force of *P* in *A*, by which it leſs Counter-Acts to *T*, and therefore is Drawn nearer to it, as alſo when *P* is in *B*, the ſame Expanſive Force from *S* Deſtroys ſome of the Contractive Force in *T*, by which it leſs Counter-Acts to the Force of *P* in *B*, and therefore Approaches nearer to it, which is not done in *C* and *D*, where the Expanſive Force Acts nearly alike upon both, and conſequently thoſe Points, and ſuch, which are Adjacent to them, are farther Removed from the Body *T*; but how theſe Phænomenons are Accounted for by a Gravitating Force, which Draws *A* towards *S*, and Repells *B* from *T* is not, as we have Shewn, nor can be Explained; This is ſaid Excluſive of the Excentricity of the Orbit, and the Motion of the Apſides, for by that the Body *P* may Recede farther from *T* in the Syzygiæ than in the Quadratures, as is Affirmed in this Philoſophy.

3*d*. FROM the ſame Expanſive and Contractive Forces, it is alſo Evident, that the Aux or the Summa Apſis *B* will be Regreſſive or Move towards *G*, when the Body *P* is in *C*, or in it's Quadrature; Becauſe, being there Retarded in it's Motion, if it were to Proceed round it's Orbit with the ſame Diminiſhed Celerity, it would be neceſſary for *B*, or the Summa Apſis, to be Carry'd towards *G*, that it may Arrive at the Point of the Orbit, or the Summa Apſis, from whence it ſet out, in the ſame Periodical Time; On the Contrary, when the Body *P* is in the Syzygia *A*, and is Moved with a Greater Velocity, the Aux or the Summa Apſis *B* will be Progreſſive towards *H*; Becauſe, the Motion of the Body being now Accelerated, if it were Carry'd with the ſame Acceleration thro' the Reſt of the Orbit, it would come too ſoon to *B*, and which therefore is Removed towards *H*, that it may ſtill obſerve the ſame Periodical Time in it's Revolution; Alſo for the ſame Reaſon, when the Body *P* is in *D*, it's other Quadrature, the Summa Apſis is Carry'd *in Antecedentia* from *B* towards *G*, and when in the Syzygia *B*, *in Conſequentia*; And ſince the Acceleration is Greater than the Retardation, the Summa Apſis, in each Revolution of the Body *P*, is Carry'd *in Conſequentia*.

Sir Iſ. Newt. Princip. Prop. 66. Corol. 6, 7, 8. Lib. 1. Dr. Gregory's Aſtronom. Prop. 8, 9, 10, 11. Lib. 4.

AND from hence it will likewiſe follow, that, when the Apſides are in the Syzygiæ, they will have a Swifter Progreſſion, and, when in the Quadratures, a Slower; Becauſe the Body *P* is more Accelerated in the Syzygiæ, when the Apſides are in the Syzygiæ, than when they are in the Quadratures, ſince the Triangle *CST* of the Expanſive Force, (by which *P* is Retarded, when in *C*, and is Leſs ſo in *P*, where the Triangle *PST* is Leſs) is Leſs, when the Apſides are in the Syzygiæ, than when in the Quadratures; as alſo the Expanſive Force from *S* makes a Greater Difference betwixt the Contractive Forces of *A* and *T*, and *T* and *B*, when the Apſides are in the Syzygiæ, than when they are in the Quadratures, becauſe in the Firſt Caſe there will be originally a Greater Difference betwixt the Contractive Forces, which Difference the Expanſive from *S* will Increaſe, and in the Laſt there will be a Leſs Difference betwixt them, and which therefore will not be ſo much Increaſed by the Action of the ſaid Expanſive, but it has been before ſhewn, that the Greater the Difference is betwixt the Contractive Forces, the more Force will be ſpent Sideways, and the Body *P* thereby Accelerated in it's Revolution.



THERE are therefore in this Solution only Two Difficulties Remaining; 1*ſt*, How the Removal of the Apſis backward or forward to make the ſame Periodick Time of the Body *P* in it's Orbit is to be Explained; 2*d*, How it can be Proved, that the Acceleration of *P* is Greater, in the Whole, than it's Retardation, ſo as to Cauſe a Progreſſion of the Apſides.

As to the Firſt it may be ſaid, that at the ſame Time, that the Expanſive Force from *S* Retards the Body *P* in *C*, or the Quadrature, there is likewiſe a Reflection of it from *P* in *C* to *B*, by which the Aux or the Summa Apſis is Protruded from *B* towards *G*, and by which it becomes Regreſſive.

ON the other Hand, when *P* is in *P*, *A*, and *F*, the Expanſive is Diverted towards *G*, by which it is Repell'd back towards *B* and *H*; when again *P* is in the Quadrature *D*, the Expanſive is Reflected towards the Parts *B* and *H*, and hinders the Progreſſion of *G* or *B* towards *H*, or rather makes it Regreſſive; and laſtly, when *P* is in *G*, *B*, or *H*, the Expanſive Force Carrys *B* forwards by a Reflection of it from *G* to *B*, and *B* to *H*.

As to the Second, that the Acceleration is Greater than the Retardation in the whole Orbit, is manifeſt, becauſe the Retardation of *P* Proceeds from the Expanſive Force, as before Explained, and in which the Difference of the Contractive Forces obtains little or no Effect, but the Acceleration of it Ariſes from a Double Cauſe, from the Expanſive Force leſs Obſtructing it's Motion, and from it's Increaſing the Difference of the Contractive Forces betwixt *T* and *P*.

Whatever Objections may be made againſt this Solution, they perhaps would Vaniſh, if we knew more Perfectly the Laws of the Expanſive and Contractive Forces, but whatever they are, as I am ſufficiently aware, what they are or can be, yet as this Solution Depends upon Principles, which are the ſame, as it Connects all theſe Phænomenons together, and makes them to have a Dependance upon each other, ſo it is Preferrable at leaſt to the Preſent Account, which Introduces New, and Diſtinct, and Independent Propoſitions to ſolve the Motion of the Apſides, and perfectly Different from what are uſed to Explain the Acceleration and Retardation of the Body in it's Orbit.

Sir Iſ. Newt. Corol. 6. Prop. 66. Lib. 1.

Thus First, It is ſaid, that the Centripetal Force of the Central Body *T*, by which the Body *P* is Retained in it's Orbit, is Increaſed in the Quadratures by the Addition of the Force *LM*, and is Diminiſhed in the Syzygiæ by the Ablation of the Force *KL*, and by Reaſon of the Greatneſs of the Force *KL* is more Diminiſhed than Increaſed; conſequently, if the Centripetal Force of *T*, by which *P* is Retained in it's Orbit, is Leſs in the Syzygiæ than in the Quadratures, ſince before by the Action of *MN*, *P* in *A* was Drawn towards *S*, and in *B* Repelled from *T*, it is Manifeſt, that from both theſe Cauſes *P* muſt Recede from *T* much more in the Syzygiæ than in the Quadratures, and yet this Philoſophy at the ſame Time Teaches us to Believe, that *P* is farther Diſtant from *T* in the Quadratures than in the Syzygiæ, and that the Curvity of the Orbit is Greater in *C* and in *D*, than in *A* and *B*.

Second, This Centripetal Force of the Central Body *T* is ſaid to be by *Corol.* 2. *Prop.* 4. in a Reaſon Compounded of the Simple Reaſon of the Radius *TP* Directly, and of a Duplicate Reaſon of the Periodical Time Inverſely, and therefore, by the firſt Article, this Compound Reaſon is Diminiſhed by the Ablation of the Force *KL*, and conſequently the Periodical Time, if the Radius *TP* Remains the ſame, is Increaſed in a Subduplicate Reaſon, in which that Centripetal Force of the Central Body *T* is Diminiſhed, and therefore, the Radius being Increaſed or Diminiſhed, the Periodical Time is more Increaſed, or leſs Diminiſhed than in a Seſquiplicate Reaſon of this Radius, by *Corol.* 6. *Prop.* 4. In Anſwer to which, *Corol.* 2. *Prop.* 4. has been already Examined and Refuted, as likewiſe *Corol.* 6. *Prop.* 4.

Granting which, if the Periodical Time is Increaſed by the Ablation of *KL*, which therefore muſt be in the Syzygiæ, the Velocity is Diminiſhed in the Syzygiæ, as the Periodical Time is Increaſed, whereas, before, we were Informed, that the Body *P* was Accelerated in the Syzygiæ, and Retarded in the Quadratures, by the Action of *MN*; and yet now by the Ablation of *KL*, it ſeems, it is Retarded in the Syzygiæ, and I ſuppoſe by the Addition of *LM* for the ſame Reaſon Accelerated in the Quadratures, tho' theſe Forces Act at the ſame Time, and obtain their Effects together, that is, *MN* which Accelerates, and *KL* which Retards in the Syzygiæ, as alſo, *MN* which Retards, and *LM* which Accelerates in the Quadratures.

Sir Iſ. Newt. Princip. Prop. 66. Corol. 7. Dr. Gregory's Aſtronom. Prop. 8. 11. Lib. 4.

Third, It is Affirmed, that in the Quadratures, where *MN* Vaniſhes, the Force, with which the Body *P* is Urged towards the Body *T*, is Compounded of the Force *LM*, and of the Centripetal Force, with which the Body *T* Attracts the Body *P*; the Force *LM*, if the Diſtance *PT* is Increaſed, is likewiſe Increaſed nearly in that Proportion, and the Latter Force Decreaſes in a Duplicate Reaſon of the ſame Diſtance, and therefore the Sum of theſe Forces together Decreaſes in a Leſs than a Duplicate Reaſon of the ſaid Diſtance *PT*, and conſequently, by *Corol.* 1. *Prop.* 45. it Cauſes, that the Aux or the Summa Apſis is Regreſſive, or Moves *in Antecedentia*.

On the Contrary, In the Syzygiæ, the Force, by which the Body *P* is Urged towards the Body *T*, is the Difference betwixt the Force, with which the Body *T* Attracts *P*, and the Force *KL*, and becauſe the Force *KL* is Increaſed almoſt in Proportion to the Diſtance *PT*, That Difference Decreaſes in a Greater than a Duplicate Reaſon of the ſaid Diſtance; and therefore, by *Corol.* 1, *Prop.* 45. it Cauſes, that the

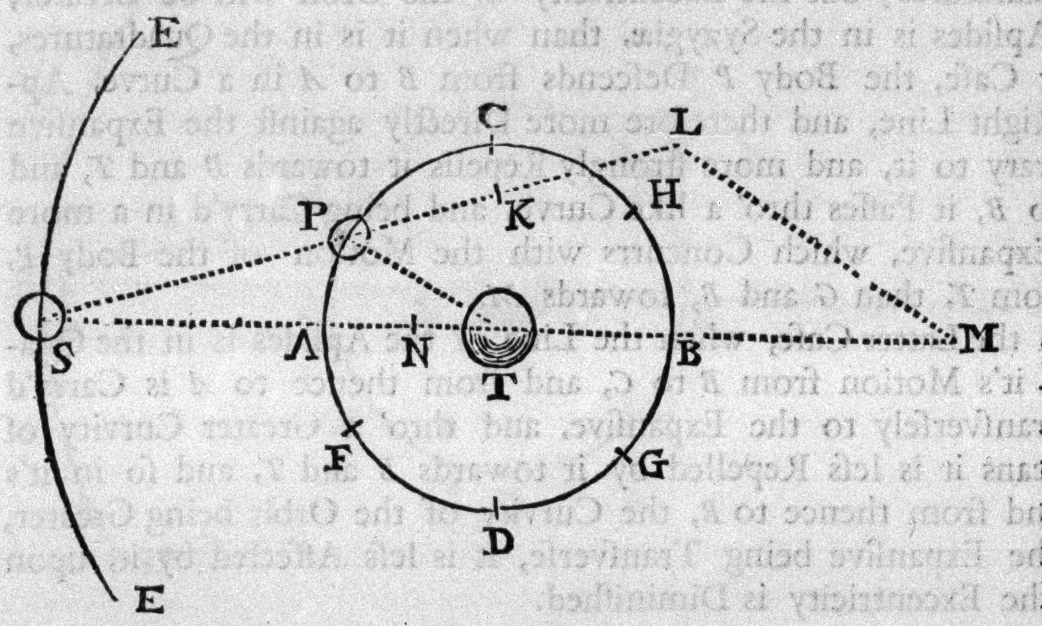
Aux or the Summa Apſis is Progreſſive, or Moves *in Conſequentia*, and ſince *KL* is Twice as big in the Syzygiæ, as *LM* in the Quadratures, the Exceſs in the whole Revolution will fall on the Side of *KL*, which will Carry the Aux *in Conſequentia*.

In Reply to which we have ſhewn, that this 45*th* Propoſition, and it's 1*ſt* Corollary is not Proved, that there is no Account given of the Revolution of the Ellipſis, and conſequently of the Apſides, that this Departure from the Duplicate Proportion being the Reaſon of the Progreſs or Regreſs of them is a Chimæra, and that we may as well take any Thing elſe to ſolve ſuch Progreſſion or Regreſſion, as the aforeſaid Deviation from the Duplicate Proportion. Beſides which, Granting the moſt, tho' there ſhould be a Receſs from the Duplicate Proportion, ſuppoſing the Apſides or the Ellipſis were Moved, it is not ſhown, that ſuch a Receſs from the Duplicate Proportion is a Cauſe of their Motion, which is Preſumed and Unaccounted for.

And Laſtly, The Revolving of Ellipſes or Orbits at once is a Mathematical Scheme and Projection, but to Imagine there is ſuch a Thing in the Heavens, is bringing us back to the Old and Exploded Epicycles, and Allowing that to the Modern Ellipſes, which we would not Grant to the Circles of the Antients.

Yet all theſe Various and Independent Matters are to be Confeſſed and Acknowledged, and Twenty more, in order to Prove this Progreſſion and Regreſſion of the Apſides, which at Length is not Obſerved in any of the Planets, in Reſpect of which they are Eſteemed Quieſcent, and all Calculations made concerning them, are upon the Suppoſition of their being ſo ; Notwithſtanding which, this Doctrine is laid ſo General, as to make us Think and Believe, that even their Apſides are Progreſſive and Regreſſive likewiſe, for what is here Demonſtrated ſeems to Relate not only to the Secondary Planets, but the Primary.

Sir Iſ. Newt. Princip. Prop. 14. Lib. 3. Dr. Gregory's Aſtronom. Prop. 43. Lib. 1.



To blind this Buſineſs of the Apſides ſtill farther, we have a Great ado made about the Seſquiplicate and Duplicate Proportions of the Diſtance *PT*, whereas we have before Obſerved, that whatever Solutions we may give of the Heavenly Bodies, as to their General Appearances, it is nothing Leſs than a Piece of Oſtentation and Vanity to pretend to Aſcertain the Preciſe Diſtances of the Planets from the Sun, or from each other, by any Inſtruments Aſtronomers can make uſe of; And this I am the more Confirmed in, when I have known good Mathematicians, in the Meaſuring the Height of a Turret only, of no more than Fifty Yards, to be Miſtaken in their Calculations, and to Differ from each other Two or Three Yards, as ſome of this College, where I now Write, may well Remember.

4*th*. From the ſame Expanſive and Contractive Forces we may Explain the Increaſe and Decreaſe of the Excentricity of the Orbit *BCAD*, for if the Body *P* is ſuppoſed to Deſcend from the Upper to it's Lower Apſis, namely, from *B* to *A*, where the Apſides are in the Syzygiæ, it is manifeſt, that the Expanſive Force from *S* will Cauſe *P* to Deſcribe an Orbit Interior to the Elliptick *BCA*, towards the Parts *CA*, ſo as to make *A* Approach nearer to *T*, by which the Excentricity will be Increaſed.

Sir Iſ. Newt. Princip. Prop. 66. Corol. 9. Lib. 1. Dr. Gregory's Aſtronom. Prop. 12, 13. Lib. 4.

First, Becauſe the Expanſive Force, Acting againſt *P* in it's Deſcent from *B* to *C*, and from thence to *A*, Repells it in every Step towards *B*, and conſequently, *BHC* from *T*, and *CPA* towards it.

Second, Becauſe the Expanſive Force from *S* Acting more ſtrongly upon *A* than upon *B*, the Contractive Force of *A* is thereby Diminiſhed, and conſequently does

not

1

not Attract *T* ſo forcibly towards it, from whence the Contractive Force of *T* has a Greater Influence to Draw *P* in *A* towards it ſelf, and *P* in *A* by that means comes nearer to *T*.

If therefore *P* was to Aſcend from *A* to *D* and *B* with the ſame Conditions, as it Deſcended from *B* to *C* and *A*, it would Deſcribe *ADB* juſt the ſame kind of Orbit, and Equally Excentrical with *BCA*; But as the Expanſive Force from *S* Acts now the ſame Way with the Motion of the Body *P* in it's Aſcent from *A* to *D* and *B*, it Impells the Body *P* nearer to *T*, in it's Paſſage from *A* to *D* than in it's Paſſage from *C* to *A*, and Repells it farther from *T* in it's Paſſage from *D* to *B*, than in that from *B* to *C*, upon which Account the Excentricity is again Increaſed, and there is one Part of the Orbit Deſcribed Interior to *AD*, and another Exterior to *DB*.

From whence it follows, that the Excentricity of the Body *P*, Revolving in an Excentrical Orbit, is twice Changed in every Revolution, and that it is the Greateſt, when *P* is in the Syzygiæ, and the Leaſt, when in the Quadratures, and that in it's Paſſage from the Quadratures to the Syzygiæ, it is continually Increaſed, and in it's Paſſage from the Syzygiæ to the Quadratures, it is continually Diminiſhed.

Suppoſing now the Line of the Apſides to be placed in the Line of the Quadratures *CD*, ſo that the Aux or Summa Apſis ſhould be in *C*, and the Ima Apſis in *D*, it is Plain for the ſame Reaſons, as before, that the Greateſt Excentricity will be in *A* and *B*, and the Leaſt in *C* and *D*, that is, the Greateſt will be in the Syzygiæ, and the Leaſt in the Quadratures; but the Excentricity of the Orbit will be Greater, when the Line of the Apſides is in the Syzygiæ, than when it is in the Quadratures, Becauſe, in the Former Caſe, the Body *P* Deſcends from *B* to *A* in a Curve, Approaching nearer to a Right Line, and therefore more Directly againſt the Expanſive Force, which Acts contrary to it, and more ſtrongly Repells it towards *B* and *T*, and in it's Aſcent from *A* to *B*, it Paſſes thro' a like Curve, and being Carry'd in a more Direct Stream of the Expanſive, which Concurrs with the Motion of the Body *P*, it is Repulſed farther from *T*, than *G* and *B*, towards *M*.

On the Contrary, in the Latter Caſe, when the Line of the Apſides is in the Quadratures, the Body *P* in it's Motion from *B* to *C*, and from thence to *A* is Carry'd more Obliquely and Tranſverſely to the Expanſive, and thro' a Greater Curvity of the Orbit, by which means it is leſs Repelled by it towards *B* and *T*, and ſo in it's Motion from *A* to *D*, and from thence to *B*, the Curvity of the Orbit being Greater, and it's Paſſage thro' the Expanſive being Tranſverſe, it is leſs Affected by it, upon both which Accounts the Excentricity is Diminiſhed.

From whence it is conſequent, that, in ſeveral Revolutions of the Body *P* compared with each other, the Excentricity of it's Orbit is the Greateſt, when the Apſides are in the Syzygiæ, that it is from thence Perpetually Diminiſhed in the Paſſage of the Apſides from the Syzygiæ to the Quadratures, where the Excentricity is the Leaſt, and in the Paſſage of the Apſides from the Quadratures to the Syzygiæ, that it is again Increaſed.

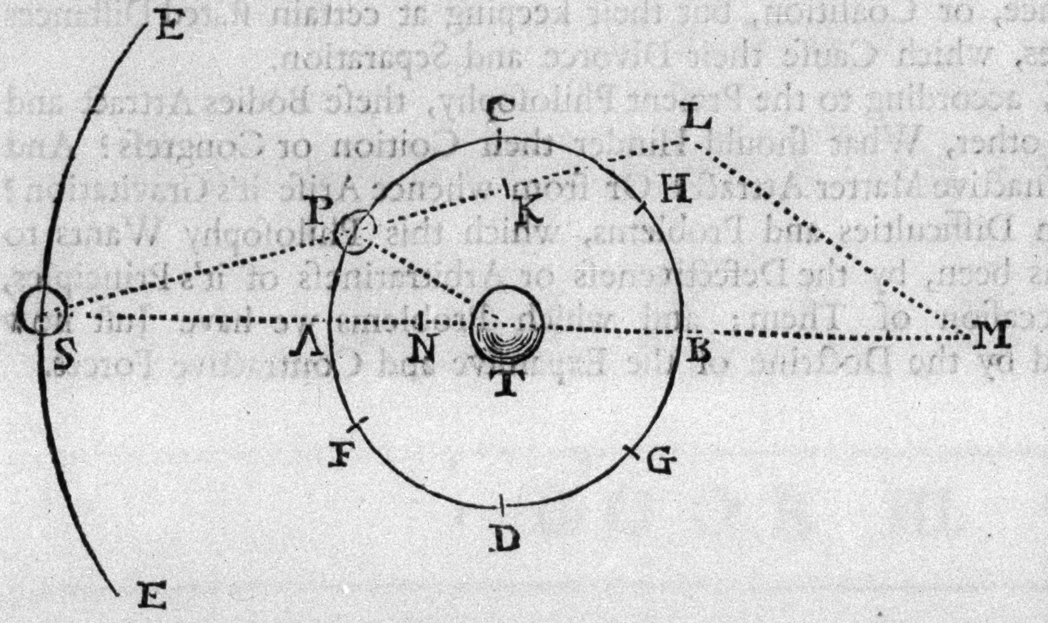
Having given our own Explanation of the Varying Excentricity of the Orbit *BCAD*, and having before Examined into that of the Preſent Philoſophy, it will be ſeen by a Compariſon, which Account is the more Probable.

Sir Iſ. Newt. Princip. Prop. 66. Cor. 10, 11, 12. Lib. 1. Dr. Gregory's Aſtronom. Prop. 14. 15, 16. Lib. 4.

5th. We ſhall therefore Proceed to the Errors in Latitude, which likewiſe are Explicable from theſe Expanſive and Contractive Forces; Let *EST* be an Immoveable Plane, and *BCA* Raiſed above, as *BDA* is Depreſſed beneath it, and conſequently in this Poſition, the Line of the Nodes *BA*, in which the Plane *BCADB* Interſects the Immoveable one *EST*, is in the Syzygiæ, when the Body *P* therefore is in *B* or in *A*, the Expanſive Force from *S* Acting according to the Direction *SA* or *SB* can make no Alteration in the Inclination of the Orbit *BCA* to *EST*, but when the Line of the Nodes is in the Quadratures *CD*, and the Body *P* is in *A* Elevated above the Immoveable Plane, it is manifeſt, that *P* will be Depreſſed towards the ſaid Plane by the Action of the Expanſive Force, for the ſame Reaſon, that *P* is Accelerated to *A* in it's Deſcent from the Quadrature to the Syzygia; becauſe there is a Leſs Expanſive Force betwixt *P* in *A*, and the Immoveable Plane, than there is above it, and when *P* is in *B* Depreſſed below the Immoveable Plane, it is by the ſame Exceſs of the Expanſive Force beyond *P* made to Approach to the ſaid Plane, for all the Expanſive Force beyond the Immoveable Plane in either Caſes is to be neglected, as Acting another way, and not Contrary to, or againſt the Inclined one *CAD* or *CBD*.

From hence it therefore follows, that the Inclination of the Orbit of *P* to the Immoveable Plane is the Greateſt, when the Nodes are in the Syzygiæ, and the Leaſt when in the Quadratures, all other Things being Equal, and that the ſaid Inclination is Diminiſhed in the Paſſage of *P* from the Quadratures to the Syzygiæ, and is again Increaſed in it's Paſſage from the Syzygiæ to the Quadratures, and conſequently, when *P* is in the Syzygiæ, the Inclination of the Planes is the Leaſt, which Returns to it's former Magnitude, when *P* Arrives at the next Node; Alſo in the Paſſage of the Nodes from the Syzygiæ to the Quadratures, the Inclination of the Planes is Diminiſhed and is the Leaſt, other Things being Equal, where the Nodes are in the Quadratures, then it Increaſes by the ſame Degrees by which it before Decreaſed, and upon the Return of the Nodes to the Syzygiæ, the Inclination of the Planes obtains it's firſt Magnitude.

The next Thing to be Accounted for is the Regreſſion of the Nodes, which Intirely Depends upon the Explication, which is Given of the Inclination of the Orbit's being Increaſed and Diminiſhed by Turns, and therefore, what the Action of *NM* is ſuppoſed to do in the Former Caſe, and which is Apply'd to the Latter, the Expanſive Force from *S* will afford us a ſufficient Solution of; namely, why the Planes are Differently Inclined in the Syzygiæ and the Quadratures, and conſequently, why the Nodes when Placed in the Quadratures are Regreſſive, and when in the Syzygiæ Quieſcent, and in the Intermediate Places, as they partake of the Conditions of the Syzygiæ and the Quadratures, are more ſlowly Regreſſive, and therefore, why the Nodes, being either Retrograde or Stationary, will be Carry'd *in Antecedentia*.



§. 20. **Having** thus Endeavoured to Explain the Errors and Irregularities of the Body *P* in it's Orbit by the Expanſive Forces of the Sun and the Contractive of the Planets, and ſhewn what Objections lie againſt the Received Expoſition of theſe Matters, we ſhall only farther in General add, that it ſeems more Agreeable to Nature, Philoſophy, and a juſt Reaſoning, to ſuppoſe, that the Orbit of *P* is Affected by ſome Force, which is Univerſal, and which is Spread and Diffuſed round it, by which thoſe Changes and Alterations are Produced in it, than to Imagine they are Derived from the Action of Two Simple Lines *MN* and *KL*, which at the Beſt owe their Origin to a Chimerical Reſolution of Forces, which we have before Conſidered and Examined.

Some General Reaſons, why the Doctrine of the Expanſive and Contractive Forces is Preferrable to that of Attraction or Gravitation.

If it be Alledged, that it is Attributing too Great an Effect to the Expanſive Force of the Sun, to make it Capable of Repelling a whole Planet, when we do not find the Rays of it ſufficient to Remove the Smalleſt Pebble.

We Anſwer, **First**, That the very ſame Argument may be Urged againſt a Planet's being Attracted by the Sun, ſo as to make it Change it's Situation, ſince, if it could Attract a whole Planet, it might, one ſhould think, eaſily Attract any Small Part or Portion of it, which lies Looſe and Unconnected with it, and therefore Draw it from it's Surface, which we do not yet Experience in the Planet we Inhabit.

Second, The Reaſon, why either the Attractive or the Expanſive Force of the Sun cannot Draw or Repell any looſe Body upon the Surface of the Planet in Diſtinction from the Whole, is Plain, becauſe by the ſame Force, with which any Body is Drawn or Repelled, every other Body of the ſame Magnitude may be Drawn or Repelled, and conſequently the whole Planet, which Conſiſts of ſeveral Bodies of the ſame Magnitude or Nearly, ſuppoſe that Magnitude, what in Reaſon we will.

Third, But yet we find very ſenſible Effects of the Sun's Expanſive Force, in it's Diſſolution of Bodies, which are Inflammable, and even of Mettals by a Burning Concave, and in it's Diſſipation of Waters and Vapours; On the Contrary, that the Sun has an Attractive Power, or that any Parcels of Matter on our Earth Gravitate towards it, we have not the leaſt Intimation from any Thing we Obſerve.

Fourth, And as to the Contractive Forces, we find the Earth is Endued with ſuch a Force, by which it's Parts are Conſtipated, and Condens'd together, and Cemented with each other, and by which all Groſs Bodies Deſcend and Gravitate to it, in order to ſuch Cement and Union, in like Manner, as the Expanſive Force Diſſipates or Repells Bodies, which come within it's Sphere of Activity; That therefore other Bodies, as the Moon and Planets, which alſo are Opake and Denſe, ſhould be Endued with the ſame Contractive Force is not Improbable, or without a Foundation in Experience and Reaſon, by which their Parts Tend to each other, and by which all External Bodies, that are Groſs and Denſe, are Drawn and Incited to a Conjunction with Them; If therefore ſeveral Bodies, as the Earth, Moon, and Planets Draw Different Ways by ſuch Contractive Forces, and the Sun Repells Them, the Effect will not be their Concurrence, or Coalition, but their keeping at certain ſtated Diſtances Agreeable to the Forces, which Cauſe their Divorce and Separation.

On the Contrary, If, according to the Preſent Philoſophy, theſe Bodies Attract and Actually Tend to each other, What ſhould Hinder their Coition or Congreſs? And how can a Paſſive and Unactive Matter Attract? Or from whence Ariſe it's Gravitation? Which are all of Them Difficulties and Problems, which this Philoſophy Wants to have Solved, after it has been, by the Defectiveneſs or Arbitrarineſs of it's Principles, the ſole Cauſe and Occaſion of Them; and which Problems we have Juſt now ſhewn may be Explained by the Doctrine of the Expanſive and Contractive Forces.

THE

THE PRINCIPLES OF THE PHILOSOPHY OF THE EXPANSIVE and CONTRACTIVE FORCES.

BOOK III.

CONCERNING THE CHIEF PROPERTIES OF MATTER, AS ALSO, CONCERNING THE PRINCIPLES OF CHYMISTRY, ANATOMY, PNEUMATICKS, AND HYDROSTATICKS.

THE PRINCIPLES of the PHILOSOPHY OF THE EXPANSIVE and CONTRACTIVE FORCES.

BOOK III.

Concerning the Chief PROPERTIES of MATTER, as alſo, Concerning the PRINCIPLES of CHYMISTRY, ANATOMY, PNEUMATICKS, and HYDROSTATICKS.

CHAP. I.

Concerning the Chief Properties of Material Beings.

§. 1. DESIGNING in this Chapter to Treat of the ſeveral Properties we find in Material Beings, I ſhall obſerve in the Firſt Place, that as they are Diverſify'd amongſt one another into Taſts, Smells, Colours, Sounds, Gravity, Extenſion, *&c.* ſo there are Various and Numberleſs Degrees in the ſame kind of Property; In the Four Firſt this is Acknowledged, but it is not ſo fully Apprehended to obtain in Gravity and Extenſion.

The Properties of Material Beings Various in Degrees as well in Gravity and Extenſion, as in Taſts, Smells, Colours, and Sounds.

THUS in Taſts we eaſily Allow of Acid, Sweet, Bitter, *&c.* and that Each of theſe have a Thouſand Varieties in them; in Smells, of Fragrant and Fœtid, with ſeveral other Intermediate ones, which are likewiſe each of them Diſtinguiſh'd into a Multitude of others, which Differ in their Impreſſions, but are the ſame in Kind and Species; Colours Appear under many Particular Forms, and each Form is Divided into New Shades and Complexions; and Sounds Conſiſt of Diverſe Notes, which are likewiſe Capable of Innumerable Modulations; And if it were not for the Prejudices we had Received from ſome Syſtems in Philoſophy, we ſhould conclude the ſame of Gravity and Extenſion; In Gravity we Experience an Infinite Number of Gradations from Gold, which is the Heavieſt Subſtance we know, to Fire, which is the Lighteſt, and has a quite Contrary Force to that of Gravitation; And in Extenſion the Eye is Filled with a Greater or Leſs Conſtipation of Parts, with which the ſame Dimenſional Space appears to be Differently Replete, and the Hand is Informed of Various Degrees of Roughneſs or Smoothneſs, of Rare and Denſe, of Solid and Fluid, to an Infinite Diverſity; but, which is the Misfortune, we have Learned to ſpeak of Gravity and Extenſion in an Abſtracted Manner, and from thence have Imagined the one, and the other, to be the Same and Invariable, tho' our Senſes Inform us, and Nature Aſſures us, that each of them Admits of as Great a Variety, as the other aforementioned Properties of Material Beings, ſo eaſy it is for our Senſes, our Reaſon and Judgment, to be Corrupted by our Abſtractions and our Fancies.

Eſſential and Accidental Properties of Matter Diſowned and Refuted.
Princip. of Natur. Philoſ. Chap. 6, 7, &c. Part 1.

§. 2. ANOTHER Thing we muſt obſerve in Reſpect to the Properties of Material Beings is, that they are Generally Diſtinguiſh'd into Eſſential and Accidental; Solidity and Extenſion are in the Number of the Firſt, and Taſt, Smell, Colour, and Sound Appertain to the Laſt, becauſe the Firſt are found in all Kinds of Matter, whereas the other are not; On the Contrary, Matter, when Defined in General, we have formerly ſhewn to be a Creature of the Mind, as well as it's Two Eſſential Properties, Solidity and Extenſion, and when we come to any Particular Portions of Matter, as they Exiſt in Nature, thoſe, which are Termed Accidental Properties, will be as Eſſential to thoſe Portions of Matter, in which they Inhere, as any other the moſt Eſſential Properties of it; Beſides the Dividing the Properties of Matter in this way is making our Senſations the Standard of the Real Qualities of it; Thus if we Exclude Smell from being Eſſential to Matter, becauſe we have no Senſations of it in ſeveral Portions we are Converſant with, in many of thoſe Portions even Dogs and ſeveral other Brutes will Convince us of our Miſtake, and in all, it is not certain, but ſome Animals or Inſects may Receive thoſe Senſations from it, which we find Impoſſible in our ſelves; What therefore we are to do, is to Conſider the Properties of Matter, as they Exiſt in it, without any ſuch Frivolous and Idle Diſtinctions, Formed by our Fancies, and Contrived to ſerve our Particular Hypotheſes, and to Try, whether we can give the Subſtratum or Eſſence of it, and from thence we ſhall know, what Properties are Eſſential to and Immediately Derived from it.

What the Eſſence or Subſtratum of Matter is, Proved from the ſeveral Properties of it.

§. 3. THE Subſtratum or Eſſence of Matter therefore I Take, and Think I may Affirm, to be Action or Force, and if I can Produce thoſe Actions and Forces, which will not only ſolve all the Phænomenons of Matter, which we are Acquainted with by our Senſations from it, but even thoſe, which may poſſibly Arrive to other Animals of a Diſtinct Nature and Species from us, I hope I ſhall have Given a full Account not only of the Eſſence of Matter, but of it's Real and Eſſential Properties, for I know of no other that belongs to it, the Accidental ones being only, as we before ſaid, either Calculated according to our own Senſations in Nature, Abſtracted from thoſe of other Animals, or upon our own Hypotheſes in the Corpuſcular Scheme.

THAT Action or Force in General is the Eſſence or Subſtratum of Matter, is Evident from this Plain Axiom, that it would be Impoſſible for us to have any Senſations from Matter, unleſs by ſome Kind of Action or other Impreſs'd upon our Minds from it, we ſhall Inſtance in thoſe already Mentioned.

Princip. of Natur. Philoſ. Chap. 10. Part 1.

TAST is Produced by an Immediate Application of the Matter to the Organ of Senſe, either therefore this Senſation muſt be Cauſed by the Action of the Mind without any Influence from Matter, and the Mind would perceive Taſt without ſuch Application of Matter to the Organ, which is Impoſſible, or elſe by the Figure of the Corpuſcles, which Compoſe this Matter, which has been Confuted in our *Principles* of *Natural Philoſophy* in the Chapter of Taſts, or elſe it muſt be by the Agitation and Motion of the Parts of this Matter (which we here ſuppoſe not to be a Fluid but a Solid and Quieſcent Body) by the Saliva without any Particular Force in the Matter, and then all Taſts of Solid and Quieſcent Bodies would be the ſame, or laſtly, by ſome Peculiar Action or Force in the Matter it ſelf, which is what we Aſſert and Defend.

Princip. of Natur. Philoſ. Chap. 10. Part 1.

SMELL is Cauſed either by Effluviums from the Odorous Body, if the Corpuſcular Account Prevails, or by Small and Minute Percuſſions, and Infinitely ſhort Vibrations, or Momentany Impreſſions of it, on the Ambient Plenum, Air or Æther, which we Maintain; if the Laſt, the Caſe is Evident, that there muſt be ſome Force or Action in Matter, from whence theſe Gentle Strokes are Promoted thro' the Æthereal Fluid to our Organs of Senſe, if the Firſt, the Arguments, which we have Alledged againſt ſuch Effluviums in the ſame Chapter, and againſt the whole Atomick Syſtem are to be Anſwered, and therefore want no Repetition here.

COLOUR Proceeds from the Reflection of the Rays of Light, which is either Heterogeneous and Diſſimilar in it ſelf, and Conſiſts of Various Colours, which are

Connate to it, and Originally in it, which the Preſent Philoſophy Affirms, or it is Homogeneous and Alike, and Receives it's New Forms from the Impreſſions and Minute Percuſſions of Natural Bodies, which we Propoſe; if the Former, our Chapters Writ againſt the Modern Explanations of Light and Colours are to be Review'd and Refuted, if the Latter, it is again manifeſt, there muſt be ſome Power, Force, or Action in Bodies Peculiar to them, which occaſions thoſe Changes and Alterations in the Luminous Subſtance.

Princip. of Natur. Philoſ. Chap. 2, 3, 4, &c. Part 2.

SOUND is Confeſſed on all Hands, for here the Corpuſcles of Matter and the Atomical Philoſophy are entirely Excluded, to be the Effect of Vibration, Percuſſion, or Elaſticity; and ſince Sounds are Different, where the External Percuſſion is the ſame, the Internal Percuſſions, Vibrations, or Elaſticities of the Sonorous Bodies muſt be Different, and therefore owing to Peculiar Forces, Actions, or Minute Vibrations in the Bodies themſelves.

GRAVITY, If Different in the ſame Quantity and Portion of Matter, which is what we Aſſert, muſt Ariſe from a Different Innate Force or Action in it, and the like may be ſaid of Solidity and Extenſion, which we ſhall more Particularly Conſider.

SOLIDITY is only Felt by us, but Extenſion is both Felt and Seen, if therefore we ſhew, that theſe Senſations could not be had, unleſs from ſome Certain Action in Matter, we ſhall Prove, that thoſe Properties of Matter, which are Eſteemed to be the moſt Eſſential, Derive their being ſo from the Action of it.

SOLIDITY is to be Conſidered Two ways, either as it is Defined in General to be an Excluſion of all other Bodies out of the Space or Dimenſions, which any Certain Body Poſſeſſes, or as it is an Actual Senſation; In the Firſt Senſe, it is only an Abſtracted Notion, and a Fancy and Creature of the Mind, thus Water, or Air, or Æther, is as Solid as Gold, as there is no Difference in the Impenetrability of them; But does any one Really Feel or Perceive, that there is no Diſtinction betwixt theſe Subſtances? Or that the one Excludes the other from being in the ſame Place? No, we Reaſon and Argue our Selves into ſuch an Opinion, that it is a Thing Impoſſible, becauſe Water or Air cannot be Æther, nor Æther Gold, which would be, if the one could Poſſeſs the very ſame Dimenſions, which the other does, that is, was Exactly of the ſame Nature; but that Water, or Air, or Æther, may not be Compreſs'd within the ſame Dimenſional Space, in which Gold Exiſts, can be no more Proved even from Reaſon, than that Water, if there were Forces in Nature to Compreſs it to a Nineteen Times Narrower Space than it Poſſeſſes, would not be Gold, or that Gold is not the Reſult of ſuch a Compreſſion by Real Forces Actually Exiſting in Nature; This Solidity therefore we have nothing to do with at Preſent.

IN the Second Senſe, Solidity is an Actual Senſation, by which we Perceive, that Gold Reſiſts more to a Penetration into it by our Hand or a Finger than Water does, Water than Air, and Air than Æther; but unleſs there was ſome Force or Action in Body, there could be no Reſiſtance to our Feeling of it, nor could we Feel it at all, and there could be no Difference of Reſiſtance to our Feeling, unleſs there were Diſtinct and Peculiar Actions or Forces, which made that Reſiſtance; This Appears to be ſo Plain and Evident, that there can be no Grounds to Conteſt it, and therefore all that we can ſay of Matter, as to the Solidity of it, from our Senſations is only, that it is it ſelf Real Force or Action, and Wholly and Entirely Conſiſts in it.

EXTENSION is to be Conſidered Two ways, as Solidity was, either as one Uniform, Invariable Thing, and the ſame in all Bodies, and then it is an Abſtraction and Creature of the Mind, or as an Actual Senſation; The Former will ſerve well enough to Diſcourſe of in Logicks, or in Geometrick Demonſtrations, but can ſignify nothing to Philoſophy, which Inquires into the Real Properties, which Exiſt in Nature, and therefore we muſt take the Latter; Which, as it is a True and Explicit Senſation, may be Felt and Seen, but how we ſhould Feel Extenſion, any more than Solidity, without an Impreſſion upon our Organs of Senſe, or how that Impreſſion ſhould be made without Action or Force, is Impoſſible to ſay or Imagine; nor is it Probable, that we could See Extenſion, unleſs the Body, which was Extended, was Endued with ſome Force or Action, for if it was Entirely Paſſive, there is no more Reaſon, why the Rays of Light ſhould not Flow along it's Surface, than be Reflected from it, but if there is an Action or Force in Body, which Repells the Rays, there is a juſt Argument for it's being ſeen.

THE Different Conſtipation of Parts, which we obſerve in the Extenſion of Wood, Stone, Mettals, *&c.* is a Conviction likewiſe, that this Force or Action is Different in Bodies; and the Various Colours of them Confirm the ſame Opinion, ſince we have ſhewn in our *Principles* of *Natural Philoſophy*, and in the Chapters Relating to Colours, that the Accounts, which have been Given of them, by *Deſcartes* or Sir *Iſ. Newton*, upon the Hypotheſis of a Similar and Paſſive Matter, are liable to Many and Invincible Objections; And till we find Equal Difficulties Chargeable upon an Active Matter, we muſt beg Leave of the Philoſophers to Depart from them into thoſe Sentiments and Perſwaſions.

What the Actions of Matter are, and that they Conſiſt of Various Degrees of the Expanſive and Contractive Forces Exerting themſelves Differently in the ſame Individual Points of Space.

§. 4. SINCE therefore all Matter Depends upon, and Conſiſts in ſome Force or Action, the next Inquiry will be, what that Force or Action is, which we Diſtinguiſh into the Expanſive and Contractive, and which has hitherto led us thro' all the Mazes and Labyrinths of Nature; It has been Generally thought, of which Opinion the Preſent Philoſophy Appears to be, that a Double Force or Velocity will Carry a Body in the ſame Time to a Double Length, and a Triple Force or Velocity to a Triple one, likewiſe on the Contrary, that a Body Carry'd with the ſame Velocity in Double the Time will Deſcribe a Double Length, and in Triple the Time a Triple one; but it ſeems to have no Notion of a Double or a Triple, or any other Multiple Force or Velocity Exiſting in the ſame Space, and in the ſame Time, which the Expanſive and Contractive Forces we Defend, will Explain, and than which Nothing is more Certain and Evident.

FOR if Two Equal Balls of the ſame Matter and Subſtance are ſtruck with Two Different Forces in the ſame Inſtant of Time, the Forces Communicated muſt be Different in the very Firſt Point of their Velocity or Motion, if not, they are Equal, and Different Forces will afterwards Ariſe from an Equality of them, which is Impoſſible; if therefore they are Different in the Firſt Point of Space, thro' which they Paſs, for the ſame Reaſon they will be in a Second, Third, a Hundredth, Two Hundredth, a Thouſandth, or a Millionth, *&c.* 'Tis true a Body will be Carry'd to a Greater Length by a Greater Force, as for Inſtance, to Double the Length by Double the Force, and for that Reaſon, that there muſt be Double the Force to carry it to Twice the Length, it muſt have Double the Force to carry it the ſame Length, the Double Proportion of Effect continuing undiminiſh'd, for otherwiſe it would ſink and dye at the ſame Diſtance from the Beginning of it's Velocity and Motion, at which the other does, that is, when both the Balls have Deſcribed the ſame Length they will be Quieſcent; whereas, ſince the Ball, which has the Double Force, will be Carry'd as far again, after the other has Ceaſt it's Motion, it is plain it came with a Double Force thro' every Point of their Moving together.

I mean, if it had not an Activity and an Energy in the ſame Time, and in the ſame Space, Double to that of the Other, it could not Produce an Effect of Motion, or of Deſcribing a Space Double to that, which the other does; for nothing is a Plainer Axiom than this, than that the Time continuing the ſame and the Activity too, the Balls, which are ſtruck, muſt ceaſe their Motion at the ſame Diſtance from their Firſt Moving, and nothing can carry the one to a Double Diſtance of that of the other, excepting we ſuppoſe their Forces Double to each other in every Point of Space, in which they Move in Conjunction.

THIS Notion of Different Velocities in a Point will be ſtill more manifeſt in Forces Communicated to Bodies, which are not Actually moved by them, as in Preſſure; Thus with the Force of Screws we may Impart a Different Velocity in a Point, and in the ſame Inſtant of Time, for a Different Velocity in a Point, I call a Different Action produced in that Point, from a Various Force apply'd to the Production of it; And the ſame may be ſaid of the Preſſure of our Hands, or our Fingers, upon a Body, which is Unmoved, and of the Variety of Impulſes from Percuſſion upon Bodies, which are Solid and Reſiſting; In all which Caſes, there are Different Actions and Forces produced in the ſame Point of Space, and in the ſame Inſtant of Time, unleſs it can be ſaid or affirmed, that there is no Effect Evident, when yet the Cauſe is Apparent and Unconteſted.

The like Inſtances to theſe are ſuch, which Relate to the Revolutions of Bodies round a Center, which according to the Different Force, with which they are Agitated and Retained in their Circles, do acquire a Different Velocity; It is generally Acknowledged, that a Circular or Periodical Motion is Compounded of a Centripetal in the Curve, and a Centrifugal in the Tangent or Projectile, it muſt be alſo Confeſs'd, that the Centrifugal is Greater, as the Velocity is Greater, with which the Body is Revolved, and conſequently in every Point of the ſame Circle, there may be Different Forces or Velocities produced, which will have the Effect upon the Æther, which Surrounds it, of Different Kinds of Preſſure.

From hence it is therefore, that we perceive thoſe Various Senſations from Matter, which we do; All Bodies Solid and Fluid are Compounded of a Centripetal, a Gravitating, or Contractive Force, by which they not only Tend to the Center, but by which they are United and Cemented together, and this Force of Gravitation or Contraction is in the ſame Point of Space, and the ſame Inſtant of Time, Various and Changeable in Different Sorts and Portions of Matter; as alſo of a Centrifugal, Elaſtick, or Expanſive, which likewiſe in Different Kinds of Matter is Changeable and Various in it's own Nature; Theſe Forces therefore, together with the Infinite Mixtures and Combinations of them, are the Real Subſtratums of all Bodies, and upon which all the Properties of them do not only Depend, but from which they are Derived.

How the ſeveral Properties of a Solid Body, as Gold, are ſolved from the Expanſive and Contractive Forces.

§. 5. Thus where a Body is Solid and Heavy, Ductile, Fuſible, and Yellow, as Gold for Inſtance.

It's Solidity, by which we cannot Penetrate into it, is owing to it's Particular Degree of Contraction, by which the Parts of it Tend to one another, and to the Center, as alſo to it's Expanſive Force, by which it Repells any Force, which Endeavours to enter into the Place, which it Poſſeſſes.

It's Gravity is owing to it's Principle of Contraction towards the Earth, which is ſomething Diminiſh'd by that of it's Expanſion from it, tho' in a Small Degree.

It's Ductile and Fuſible Nature is Derived from it's Expanſive, being Aſſiſted by the Expanſive Force of Percuſſion, or that of Fire, by which it in ſome Meaſure Surmounts it's Force of Contraction.

It's Colour, which is near as Ruddy as Fire, is Derived from it's Expanſive Force, which may be probably as Great as that is, but which only Acts with that Force within it's own Dimenſions, and is only capable of making it's Impreſſions upon the Æther, which immediately Surrounds it, by Reaſon of it's being held back and detained by the much Superior Proportion of the Contractive Force, with which it is Mixt and Blended.

And from whence Appears the Neceſſity of a Plenum, ſince, if there were not ſuch an Æther, it would be Impoſſible for us to have any Senſation of this Force, or indeed of any Colour, or any Viſion in General, namely, unleſs by the Mediation and Interpoſition of it.

How the ſeveral Properties of Fire are ſolved from the ſaid Forces.

§. 6. On the Contrary, let us take Fire or Flame, that it has a Certain Degree of Gravitation or Contraction, is not only Evident from Mr. *Boyle's* Experiments, which Evince that Fire or Flame is Ponderable, but is likewiſe Manifeſt from this Plain Reaſon, that if it were not ſo, it would be Diſſipated at once, no Fire or Flame would continue together, none would ſubſiſt near this Earth, but if it had an entirely Centrifugal or Expanſive Force, it would be loſt and would Vaniſh in a Moment; Beſides Fire or Flame cannot ſubſiſt without ſome kind of Fuel, or other, to ſupport it, which always has a Contractive Force belonging to it, and with which therefore it is as conſtantly United.

But as Gold has the Greateſt Contractive Force, and perhaps the Greateſt Expanſive joined together, by which it obtains the Properties above-mentioned, ſo Fire or Flame ſeems to have the Greateſt Expanſive Force, and the Leaſt Contractive, of any other Material Being.

To it's Contractive Force it is owing, that it is not Diſſipated and Diſperſed, that it Exiſts in a Lamp or a Cinder, and Precipitates to the Earth with it,

To it's Expanſive Force it is owing, that it Dilates and Extends it ſelf to every Part, where there is a Matter, whoſe Contractive Force is not too Great to be overcome, and to be Changed and Transformed into an Expanſive by it.

By this alſo it Strikes the Æther with that Force and Velocity, which Excites either an Heat, or Burning in it, to our Senſations of Feeling, and Imparts to our Sight, by it's Impreſſions upon the Organs of that Senſe, the Strong and Vivid Red, and the peculiar Brightneſs and Luſtre, we Receive from it.

How the ſeveral Properties of Fluids are ſolv'd from the ſame Principles, and the Various Kinds of Fluids Determin'd.

§. 7. As to Fluids, what is Common to them with other Material Subſtances is derived from the aforementioned Contractive and Expanſive Forces, and what is Peculiar to them, namely, their Fluidity, ariſes from an Equal Balance betwixt thoſe Forces, by which means, tho' the Parts of a Fluid have a Certain Degree of Tendency to each other, yet being endued with an Equal Degree of Force of Retiring from each other, they accordingly ſeparate upon the leaſt External Application to Divide them, and this ſeems to be the Nature of a Perfect Fluid; But by how much more Fluids Reſiſt to a Separation of their Parts, by ſo much is the Contractive Force more Prevalent than the Expanſive, or by how much more they are Inclined or Diſpoſed to ſuch a Separation without an External Force, by ſo much is the Expanſive more Prevalent than the Contractive.

An Inſtance of the Firſt Sort of Fluids ſeems to be That of Clear and Limpid Water, which by it's Expanſive Force is capable of Reducing ſeveral Kinds of Matter, as Salts, and Earths, and Minerals, to it's own Expanſive Force, in like manner, as Fire does Combuſtible Subſtances to it's Expanſive; from whence poſſibly proceed Perennial Fountains, with their Various Mineral Taſts, which ſeem to be Produced by the Expanſive Force of Water Acting upon theſe Waterable Subſtances, if we may ſo call them, and Converting them into it ſelf, juſt as Flame Acts with a Greater Degree of the Expanſive Force upon Subſtances, which are Inflammable, from whence Ariſe the Vulcanos, as thoſe of *Ætna* and *Veſuvius*, which have continued Burning for ſo many Ages; Water has an Expanſive Force in Reſpect of Wood, which it Swells and Dilates, and which Froſt Contracts, as is Evident in Doors and the Frames of Saſhes.

Of the Second, The more Viſcous and Tenacious ones, as Oils and Glutinous Subſtances, the Latter of which, when Cooled and laid upon Wood, have ſo Great a Contractive Force, as to be Equal, if not Superior, to that of the Wood it's ſelf; and it is not certain, that when Oils are infuſed betwixt Poliſh'd Plates or Marbles, but they may have the ſame Contractive Force with Glews, tho' it is Generally ſaid, that they only keep the Air from Entering betwixt the Plates, and the Reaſon of their Adhering ſo firmly together is aſcribed to the Incumbent Preſſure of the Atmoſphere; To this kind may be added Metals in their Fuſion, and Mercury.

Of the Third, The more Spirituous ones, as all Kinds of Wine and Strong Waters, Oil of Vitriol, Spirit of Turpentine, *&c.* Alcohol or Rectified Spirit of Wine, which will of it ſelf, if a Small Quantity of it is poured into a Spoon, immediately Evaporate and become Inviſible; Alſo Air, Æther, Fire, and Flame, ſeem to have likewiſe a Greater Degree of the Expanſive Force than of the Contractive, and of the Four laſt mentioned, Æther, Fire, and Flame, appear to have ſo little of it, that, inſtead of Giving a Reſiſtance to Material Beings in their Actions, they Accelerate and Contribute to them.

All the Phænomenons of Nature ſolv'd from theſe Principles.

§. 8. All the Properties of Matter mentioned in Philoſophy are Derived from hence, whether thoſe which are Termed Accidental, or thoſe which are Called Eſſential; All the Principles in Chymiſtry, and the Operations Obſervable in it, as Fermentation, Precipitation, Coagulation, Chryſtallization, *&c.* and all the Phænomenons, which Preſent themſelves to us from the Animal, the Vegetable, or the Mineral Kingdom, all the Principles of Anatomy, and the Motion of the Lungs, of the Blood, and of the Muſcles, of the Animal Spirits, or the Nervous Juice, and the Union of the Human Syſtem with our Minds, and the Sympathy, which the one has with the other, are likewiſe Deducible from theſe Forces of Expanſion and Contraction.

The Eſſential or Philoſophick Properties of Matter, when Conſidered as Real, Accounted for from Expanſion and Contraction.

§. 9. The Eſſential Properties of Matter, according to the Corpuſcular Philoſophy, are thoſe of Extenſion, Solidity, Figure, Diviſibility, Mobility, and being, in it's own Nature, Unactive, to which we may add, with Sir *Iſ. Newton*, Attraction or Gravitation; when theſe Properties, which I call the Philoſophick ones, are only Conſidered in the Abſtract, they are, as I have already ſaid in the Firſt Part of the *Principles* of *Natural Philoſophy, Chap. 6. Book* 1. Nothing more than Creatures of the

Mind, and of thoſe there can be no other Account given, than that the Philoſopher was pleaſed, for his own Purpoſes, which he had in View, and for the Convenience of his Solutions, to make thoſe Abſtractions.

Extenſion Accounted for from hence.

BUT let us take theſe Properties, as they really Exiſt in Nature, and we ſhall eaſily find, in the Firſt Place, that Extenſion is Various and Different in Matter, both to our Sight and to our Feeling; That we See or Feel the Extenſion of Matter, I ſay is owing to it's Expanſive Force, by which it Acts, in Feeling, immediately upon the Organs of our Senſe, and, in Seeing, upon Æther, and, by it's Intermediation, upon the Eye, the Humors, and the Retina of it; We likewiſe hold, that this Action of Extenſion is by a Pulſe or a Velocity Exerting it ſelf in a Point or a Surface, without any Evident Change of it's Space or Situation; that farther, Extenſion ſeems Various to us, that is, Rarer or Denſer to our Sight, according as this Expanſive Force does Act upon more or fewer Points of the Æther, and ſo upon the Eye, and to our Feeling, as it more or leſs Affects the Organs, which Tranſmit thoſe Senſations to us.

Solidity Accounted for.

As to Solidity, by which our Finger, or any other Body, is Prohibited from Entering into the Space or Dimenſions, which another Body Poſſeſſes, ſo far as it is an Abſtracted Idea, it is a Creature of the Mind, and is of no Significance or Importance to Nature; but if we conſider Solidity, as an Actual Reſiſtance, by which one Body obtains a Force of Excluding others from Penetrating or Piercing into it's Space, unleſs by a Superior one; ſuch a Property is entirely Accounted for, both from the Force of Contraction, which keeps Matter United and Cemented together, and from the Force of Expanſion, which Repells or Subdues the Force, which attacks it; and the Various kinds of Solidity are derived from the Various Forces of Expanſion and Contraction.

FROM which it is manifeſt, that altho' there cannot be a Penetration of Dimenſions, where Solidity is conſidered and look'd upon as an Abſtracted Idea, yet there may be one in Reality, according to what has been Affirmed in the Firſt Part of the *Principles* of *Philoſophy*, that is, there may be Different Forces either of Contraction or Expanſion, or Different Degrees of Action, in the ſame Dimenſional Space; and if Gold, for Inſtance, is 19 Times Heavier than Water, ſetting aſide both their Expanſive Forces, 19 Parts of Water will be Compreſs'd into the ſame Space with one of Gold, to make that Subſtance; ſuppoſing likewiſe, that the Contractive Force is Equal to the Gravitating, which may not in fact be; ſince the Parts or Portions of Matter may Tend to each other with a Different Force and Inclination from that, with which they do to their Center, unleſs all Matter was Similar and Homogeneous, which it is not; for in that Caſe, it is reaſonable to think, that the Forces of Contraction would be exactly Equal and Correſpondent to thoſe of Gravitation.

Princip. of Natur. Philoſ. Chap. 4. §. 11. Part 1.

Figure Accounted for.

FIGURE is another Eſſential Property in the Corpuſcular Philoſophy, for which it does not Account, which is Defined and Deſcribed to our Sight or our Feeling by Diverſe Portions of Matter Exerting their Different Forces of Expanſion within certain Limits and Boundaries, in Diſtinction from the Expanſive Force of the Æther, which ſurrounds it.

THUS, becauſe a Globe or a Cube of Gold, of Glaſs, or of Marble, or Wood, or of any other Body Solid, or Fluid, Diſplays it ſelf in a Different Expanſive Force upon the Æther, or our Organs of Senſe, from the Expanſive Force of Æther it ſelf, within ſuch ſtated Terms and Limits, therefore it is, that we ſee Bodies, or feel them, to be Endued with ſuch Figures Agreeable to the Extent of their Peculiar Actions.

Diviſibility Accounted for.

ANOTHER Eſſential Property of Matter is Diviſibility, which the Corpuſcular Philoſophy knows the Uſe, but not the Cauſe of, and which Ariſes from the Expanſive Force in Matter, for if there was a Contractive Force in it, which was Infinite, and not Moderated and Allay'd by an Expanſive one, it would be Impoſſible ever to Separate one Part of Matter from another; but the Contractive Force of Matter being Finite, or being Tempered with an Expanſive, upon both theſe Accounts it is capable of a Separation; either by the Expanſive Force of Diſſolvents, as Gold by the Spirit of Nitre mixt with Sal Armoniac, and Silver and other Metals by the Spirit of Nitre alone; or elſe, by Attrition, Percuſſion, and other External Violences, which are all ſo many Expreſſions or Conveyances of the Expanſive Force of the Mind Exerted upon Material Beings.

Mobility Accounted for.

A Fifth Eſſential Property of Matter in the Corpuſcular Philoſophy is that of Mobility, which is likewiſe Explained from theſe Forces, For if any Portion of Matter, as before in Reſpect of Diviſibility, had an Infinite Force of Contraction, and the Force of Contraction was Correſpondent to that of Gravitation, or of it's Contraction to the Earth, it would be Impoſſible for any Body to be Moved; but as every Body has only a Finite Tendency of it's Parts to each other, and of all of them to the Center, and as it's Parts and it's Whole are Endued with an Expanſive Force; Upon both theſe Accounts, as before Bodies were Diviſible, ſo are They Moveable, when there is a Superior Expanſive Force, either by Springs, as in Automatons, or by Percuſſion, or by Levers, which are Derived from a Superior Expanſive Force; or by Weights, which are Derived from a Superior Contractive, and which, in ſuch a Caſe, have the Nature of an Expanſive.

The Inertia of Matter what in Reality and how the Immenſe Bodies of the Sun and Stars may be ſuſpended in Æther, as alſo the Planets, if they were not Agitated by their Actions amongſt one another, and by the Expanſive of the Sun.

THE Sixth Property of Matter, which is that of it's Inertia or being perfectly Unactive, cannot indeed be Accounted for from Forces, which are Active in that Senſe, in which we have Explained them, nor is there ſuch an Inertia of Matter in Nature; For there is no Material Being, which has not ſome Action or other belonging to it, by which we are made ſenſible of it's Exiſtence, and without which we could not be furniſh'd with any Senſation at all of it.

ALL the Real Inertia of Matter is, that it is Capable of being Moved, or in General of yielding to a Superior Force, which ſhall Act upon it, whether the Expanſive or Contractive, not that it will continue in a State of Motion or Reſt after it is once put into either; ſince it has an Innate Force in it ſelf Derived from God, which will Prevail, when the Force, which is Impreſſed upon it, Ceaſes, which it will do, unleſs that Force is Infinite, which is not the Caſe of Percuſſion, or Projection in this Philoſophy.

THUS in Fire, when Water, which in Reſpect of Fire has a Contractive Force, is apply'd to it, if in a Great Degree, the Contractive Force extinguiſhes the Expanſive, but if in a Leſs, tho' the Fire ſubmits for a Time to the Contractive of the Water, yet, when that Force is ſpent, it riſes Stronger and Livelier than before.

THUS alſo in Reſpect of the Contractive Force, or of any Solid and Heavy Body, if it is ſtruck with a Racket, when that Force is ſpent, which is Derived from Percuſſion, it Re-aſſumes it's own Contractive Force and Tends to the Center, for the Contractive Force does not only Act, ſo as to Unite the Parts of Matter amongſt themſelves in any Portion of it, but ſo as to Unite all the Portions of the Univerſe together, and the Expanſive Force Acts the Contrary way to Diſpell and Diſunite them; It muſt be farther here obſerved, that it is ſomething Wonderful and Strange, that the Great Prince and Coryphæus of the Corpuſcular Philoſophy Sir *Iſ. Newton*, whoſe Name ought not yet to be mentioned without the Greateſt Regard, ſhould aſſert this Inertia of Matter, againſt which we Contend, and from that Aſſertion, which is the Foundation of all his Philoſophy, ſhould endeavour to Prove, that Gravitation or a Centripetal Force is a Quality or Property, which belongs to all Matter in General, which is neither more nor leſs than a Contradiction.

IF it be Enquired, what would become of a Contractive or Solid Body upon Percuſſion or Projection, ſuppoſing it was at an Infinite Diſtance from all Matter, ſo as not to Gravitate to any Portion of it, we Anſwer, after that External Force, which is Communicated to it, is Loſt, or Surmounted by the Contractive of the Body, which would be at ſome Finite Diſtance from the Beginning of it's Motion, becauſe the Force, which is Impreſſed upon it, is Finite, It would Ceaſe to Move, and by it's own Contractive Force would remain Quieſcent in Æther, there being no External Force to determine it one way more than another, and it's Contractive Force having no other Effect than to make the Parts Tend Inwards, and to reſiſt Percuſſion, or any foreign Violence; The like may be ſaid of an Expanſive Body, and it's Parts Exerting themſelves Outwards; And this Probably may be the Reaſon, why that Stupendous Maſs of Matter the Sun, as alſo, the fixt Stars continue ſuſpended in Æther, and why this Earth and the Planets would do the ſame, were they not Agitated by their Actions amongſt one another, and by the Expanſive of the Sun.

Gravitation Accounted for.

THE laſt Philoſophick Property of Matter is Gravitation, which is the ſame kind of Contractive Force in Reſpect of Different Bodies, which is Exerted in the Uniteing and Cementing of the Parts of the ſame Body; but as the Contractive Force, by which the Parts of one Body Tend to each other, may differ in the Degree of it's Velocity in a Point from the Contractive Force of the Parts of a Second, a Third, or a Fourth Body, *&c.* ſo alſo the Force of Gravitation, by which Bodies Tend to others, may be likewiſe Different, albeit we may not obſerve that Difference in their Tendency to the Earth, by Reaſon of the Vaſt and Prodigious Contraction it Exerts, in Reſpect of all Bodies in General; tho' we cannot but think, notwithſtanding all the Experiments made uſe of to Prove, that Bodies Deſcend with an Equal Force to the Earth, that a Rock falling from the Top of the Alpes would be Carry'd down to it with a more Aſtoniſhing Violence, than a Pebble dropt from that Height; and in Fact, if Hiſtorians are True, The Former once fell with ſo Great a Force, as to over-whelm a Whole Village, which lay beneath, and ſunk to ſuch a Depth into the Ground, as to Produce a conſiderable Lake in the Place, where it made it's Impreſſion.

Dr. Heylin's Geography.

§. 10. HAVING thus far Gone thro' the Eſſential Properties of Matter Alledged by Philoſophers, and Endeavour'd to give an Explanation of them, we ſhall now Proceed to thoſe, which are Term'd Accidental ones, ſuch are Hardneſs, Softneſs, and Fluidity, Rarity and Denſity, Reſiliency and it's Contrary Quality, Heat and Cold, Smoothneſs and Roughneſs, Brittleneſs and Limberneſs, Taſts and Smells, Sounds, Light and Colours, Opakeneſs and Tranſparency.

The Properties of Matter Termed Accidental ſolved from the foregoing Principles, in Particular Hardneſs, Softneſs, and Fluidity, Rarity and Denſity, Reſiliency and it's Contrary Quality, Heat and Cold, Smoothneſs and Roughneſs, Brittleneſs and Limberneſs.

As to Hardneſs, it is evidently Explained by a Contractive Force, which the Greater it is, by which any Portion of Matter is Cemented together, the more Difficult muſt it be to make a Separation in it; Softneſs ariſes from a leſs Degree of ſuch a Contractive Force, and Fluidity from a nearly Equal Mixture of the Expanſive and Contractive, according to what has been already mentioned.

RARITY and Denſity, as was likewiſe ſaid before, Conſiſts in a Leſſer or a Greater Number of Parts, Exerting their Expanſive and Contractive Force, in Conjunction, in the ſame Space.

RESILIENCY is, where the Expanſive Force is Vigorous and Strong, but yet is ſo far Ty'd down by the Contractive, as not to Move conſiderably out of the Space, which the Body Poſſeſſes; and the Contrary Quality is, where the Contractive entirely Prevails over the Expanſive, which therefore does not obtain in Nature, ſince there is no Body, which has not Sound or Colour, both which are Indications of ſome Degree or other of the Expanſive reſiding in it.

HEAT is manifeſtly Derived from a Great Degree of the Expanſive, and Cold from a Great Degree of the Contractive.

SMOOTHNESS and Roughneſs many Times Ariſe from the Parts of Bodies, being leſs or more Prominent from their Surfaces, which is of no Conſideration in Philoſophy, excepting in the Corpuſcular; But we may likewiſe farther obſerve, that Bodies, which are Equally Poliſh'd, and whoſe Surfaces to all Appearance are a-like Levigated and Plane, do ſome of them feel Harſher, and others more Oily and Smooth, as in Steel and Ivory or Water, the Former of which ſeems to be Derived from it's Contractive Force being Greater than that of Ivory or Water, and it's Expanſive Force Joined with that Contractive being in a Greater Proportion to the Contractive in Steel than in the others, upon both which Accounts, there will be more Reſiſtance to the Hand, carry'd along the Surface, in the Former Caſe than in the Latter; From hence Planes Rubbed, by which the Expanſive is Excited, Feel Smooth, that is, the Hand Slips off, or is Repelled from them.

BRITTLENESS appears to Proceed from the Expanſive Force, Acquired from the Fire, by which an eaſier Separation of Matter is made, as in Steel, Glaſs, Brick; and Limberneſs from the Contractive, by which a Divulſion is more Hardly, and with Greater Difficulty performed, as in Iron, Clay, Leather and Paper, which have but a Small Degree of the Elaſtick or Expanſive.

§. 11. As to Taſts, they are Derived from the Expanſive Force, from whence Solid and Conſiſtent Bodies, which have but a Small Portion of the Expanſive, and which is kept and detained from Exerting it ſelf out of it's own Space by the much Superior Contractive, have little or no Taſt at all.

Taſts ſolved from hence, and their Various Diſtinctions Aſcertained and Accounted for.

AND Spirituous Bodies, or Fermenting ones, as alſo Vegetables, *&c.* which have the Greateſt Degree of the Expanſive Force, are Endu'd with a very Lively and Vigorous one, and on the Contrary Water, in which the Contractive and Expanſive ſeem to be in an Æquilibrium, the Taſt is Flat, Languid, and Inſipid.

ACCORDING to the Various Degrees and Proportions of this Expanſive Force, which is Superior to the Contractive, but yet is Joined with it, are our Taſts Diverſify'd, which may be Diſtinguiſh'd in General into Sweet, Bitter, Sowre, Harſh, and Smooth, and the ſeveral Degrees, Compoſitions, and Combinations of them.

From whence Sweet and Sowre Ariſes.

SWEET Ariſes from a Greater Degree of the Expanſive Force, and Sowre from a Greater Degree of the Contractive, and ſeem to have the ſame Relation to our Taſt, as Heat and Cold have to our Feeling; For as what is Sweet and Warm gives a Life and Vigour to the Mind, ſo what is Sowre and Cold makes it Shudder and Tremble: The Reaſon of which can be no other, than that, as there is an Expanſive Force in the Mind Superior to the Contractive in the Airy, ſo accordingly it is Affected with Pleaſure or Pain, as thoſe Forces Agree, and are Coincident with, or are Oppoſite and Contrary to it's own; On the other Hand it muſt be likewiſe Confeſs'd, that in the Auſtere there is a Contractive Force in the Mind Superior to the Expanſive, by which it's Thoughts are kept and retained together, and which makes it more delighted with Sowre Taſts than with Sweet, with Cold than with Heat, and with Grave and Serious Things more than with what is Light and Trivial; From too Great a Degree of the Expanſive Ariſes Madneſs and a Diſſipation of Thought, and from too Great a Degree of the Contractive Ariſes Melancholy; Wit, Jovialneſs, and Debonairneſs, are owing to the Former, and Thought, Study, and Contemplation, to the Latter; The Medium betwixt the Airy and the Auſtere is the Juſteſt.

Concerning the Expanſive and Contractive Forces of the Mind.

WHEN I affirm Expanſive and Contractive Forces to belong to the Mind, as well as to Matter, I do not affirm, that the Mind is Matter, no more than, when I aſſert, that Fire and Gold have both theſe Forces, I aſſert that Fire and Gold are the ſame; So Extenſion is Neceſſary and Eſſential to Body and to Abſtracted Space, which yet are Eſſentially Different. Beſides which, I have given my Reaſons, wherefore I am aſſur'd and perſwaded, that the Mind is a Being entirely Spiritual, as it has Thought, Perception, Memory, and Judgment, nothing of which Matter has, and as it has an Innate Force Diſtinct and Separate from it; All which I affirm is, that it has theſe Contractive and Expanſive Forces, and upon which it's Union with Matter does, in Conjunction with what has been before alledg'd, Depend; For altho' their Subſtances Differ, yet ſince they agree in their Forces of Expanſion and Contraction, by thoſe it comes to paſs, that they have a Sympathy or Coalition with each other, and are in that Senſe alſo, as in Another, which was there Mentioned, United and Cemented together.

Chap. 6. §. 28, 29, 30. Book I.

THAT the Mind has an Expanſive Force, and in Different Degrees, is Evident and Manifeſt, not only from what has been before ſaid, but from the Different Strength, which it Exerts in Percuſſion, in Walking, Running, and in all the Motions and Actions of the Body; That it has likewiſe a Contractive Force is Plain from it's Power of Reſtraining, Curbing, or Contracting thoſe Motions.

Concerning Fevers, Dropſies, and Lethargies.

See Chap. 6. §. 29. Book I.

FROM hence it is, that in Fevers, or in Drinking Spirituous Liquors to Exceſs, in which there is the Greateſt Expanſive Force of the Blood, Madneſs or a Diſſipation of Thought Enſues; And in a Lethargy or Dropſy, or in the Stone in the Kidneys, when the Serum is ſtopt and circulates back with the Blood, that is, when there is the Greateſt Contractive Force in it, and it Approaches neareſt to a Stagnancy, a Flatneſs and Languor of Thought is conſequent, and the Expanſive Force of the Mind being Diminiſh'd, it Tends to Sleep and to Slumbers; And nothing is found in Experience to Contribute more to the Real and Conſtant Vigour of the Mind, and of the Body, than a Temperate Diet both in Meats and in Drinks, that is, ſuch which have not too Great an Expanſive, nor too Great a Contractive Force in them, or in other Terms, which are not too Solid and Heavy, or too Light and Spirituous.

THE Queſtion with Phyſicians is, in the Two Extremes afore-mentioned, what is the Proper Cure for them; But, without Entering into their Arguments about Acid and Alkali, In both theſe Caſes of a Fever or Madneſs, or of a Dropſy and Lethargy, (for as to the Stone, unleſs the Obſtruction to the Paſſage of the Urine thro the Ureters can be Removed, it is Incurable, of the Fatality of which Diſtemper, I have Formerly had the moſt Melancholy Inſtance in the Death of my Deareſt Father, one of the moſt Excellent and Pious of Men) I ſay, in both theſe Caſes,

THE Firſt Method, according to this Doctrine of Expanſive and Contractive Forces, to be uſed, is the utmoſt Temperance and Regularity in Meats and Drinks, to ſee if Nature will Return to it ſelf, and it's own Proper and Peculiar Forces of Expanſion and Contraction will Prevail, which in all Likelihood they will, if theſe Diſtempers are Induced by any Exorbitancy in the uſe of either the Expanſive or Contractive Forces in them; If this does not prove Effectual,

FIRST, In Madneſs or in Fevers, it ſeems to be Reaſonable to think, that the too Great Expanſive Force in the Blood is to be Diminiſh'd and Abated; Not by Taking Blood away, becauſe, that which Remains will have the ſame Temper and Craſis, and there will be a Want of it to ſupply a Nouriſhment to the Body, and which can very hardly be made by any New Digeſtions, when the Stomach, the Entrails, the Lacteals, the Veins and Arteries, the Lungs and the Heart, are in the utmoſt Diſorder, But by Altering the Expanſive Force of it, in which Conſiſts the main Difficulty; for if we Throw Water upon Fire in a ſmall Quantity, it cauſes it to Burn the Fiercer, if in a Large, it Extinguiſhes it, but Air keeps it in a Conſtant and Equable Tenour.

WHAT therefore ſeems to be done in this Caſe is, in the Higheſt and Greateſt Fever, Firſt, to Take the Air, ſo as the Motion, by Rideing in a Chair or Litter, ſhould not Excite or Exaſperate the Expanſive Force of the Blood, but keep it in the ſame Temper, in which it is.

THE next Thing is to be Regular in Diet, and to uſe Nothing, which has an Apparent Exceſs of the Expanſive Force in it.

AND the Third to take Gradually, and by Times, thoſe Things which have the Greateſt Contractive Force in them, as Water, Cooling Draughts, and the Juice of Lemons with the Rind.

SECOND, On the Contrary in a Lethargy or Dropſy, the Contractive Force of the Blood is to be Subdued, and to be Raiſed and Excited by Expanſive Forces into a Quicker Circulation.

WHICH is to be done, FIRST, By a Temperate and Regular Diet, which has not too Great an Expanſive or Contractive Force in it.

SECOND, By Taking the Air, and by the Briskeſt and moſt Lively Exerciſes, either by Rideing, or Walking, but eſpecially by the Former, and if poſſible, in the Midſt of Froſt and Snow.

THIRD, By Making uſe Gradually, and by Times, of Spirituous and Expanſive Liquors, to Envigorate and Enrich the Blood.

THAT this Method in Dropſies is a Juſt one, I have had Experience of, from the Effect it had upon a Fellow of this College, my Good Friend, who dy'd of one, who yet, when he was given over by his Phyſicians, was wonderfully and to every Body's Admiration Reſtored by theſe Preſcriptions, ſo far as to Survive his Imagin'd Death Three Years, and which, if they had been Purſued, would have Prevented a Relapſe of his Diſtemper, which at Length was too Hard and Difficult for him to Surmount. And I do not Queſtion, if the Method, which I have mention'd in Fevers, were Followed, but Phyſicians would Find a much Greater Succeſs in their Practice upon that Malady; This, which I wrote many Years ago, I Perceive is now Confirmed by Dr. *Hancock's Febrifugum Magnum*, which is nothing elſe but Water. All Diſtempers or moſt of them lie betwixt theſe Two Extremes, a Fever or Phrenzy on the one Hand, and a Dropſy or Lethargy, and Melancholy on the other.

A farther Proſecution of the Theory of Taſts

BUT to Return to Taſts, Sweet we have Affirmed to be owing to the Expanſive Force of Bodies, and Sowre to the Contractive; And it is Evident, that the Sweetneſs of Sack has a more Expanſive Force upon the Mind, that is, Intoxicates and Diſſipates it more than the Juice of an Apple or a Lemon, as the Heat of Fire Creates a Greater Diſorder in it than the Severity of a Froſt, the Firſt of which is an Expanſive Force and the Laſt a Contractive. And from hence, as was ſaid before, it is, that Phlegmatick Perſons, or thoſe, who have a Greater Degree of the Contractive Force in their Conſtitutions, are more Pleaſed with Cold Weather, and thoſe who are more Sanguine, with Heat and with Fire; which will alſo give a Reaſon, why the World will be always Divided, ſo long as there are theſe Two Principles in our Natures; The Witty, the Chearful, and Lively, under what Denominations of Religion or Learning ſoever, will be Averſe to the Serious, the Grave, and the Contemplative, and theſe to the Others, From the Difference of the Expanſive and Contractive Forces in Them.

From whence Bitter Ariſes, and how the Bark of Peru *Operates in Agues and Intermitting Fevers.*

If therefore Sweet is Derived from the Expanſive, and Sowre from the Contractive, Bitter, which is a Mixture of Both, will Proceed from a Mixture of thoſe Forces; Which is the Reaſon, that Bitters in General are Found and Experimented to be Wholeſome and Salutary to us, eſpecially, that of the Bark of *Peru*, in Agues and Intermitting Fevers, where the Expanſive and Contractive Forces are in a Perfect Struggle, and have in a Manner an Equal Contention with each other, which is manifeſt from the Hot and Cold Fits, the Conſtant Attendants of that Diſtemper.

See Chap. 6. §. 31. Book 1.

The Way of Operation therefore of this Grand Specifick in Medicine ſeems to be by it's Applying both to the Expanſive and Contractive Forces in the Blood, and Subduing the Exceſſes of both of them by thoſe Innate Forces of Expanſion and Contraction, of which it is Compounded, the Expanſive Force of the Blood, by the Contractive of the Bitter, and the Contractive Force of the Blood, by the Expanſive of it, But being more Expanſive than Contractive, it's Greateſt Influence is upon the Contractive of the Blood, from whence theſe Diſtempers ſeem to Ariſe.

From whence a Smooth Taſt and an Harſh one.

A Smooth Taſt, as that of Oil, and a Rigid or an Harſh one, as that of a Sloe, Ariſe from the ſame kind of Forces, which belong to Bodies which Feel ſo, in like Manner, as Sweet and Sowre are to Taſt, what Warm and Cold are to our other Senſations; and conſequently, the Harſhneſs of Taſt appears to be Derived from a Greater Contractive Force in the Sloe, Compared with that of Oil, and a Greater Expanſive Force in the Sloe, Compared with the Contractive of it, than in the Oil Compared with it's Contractive; the Greater Expanſive will make it ſtrike with more Force upon the Palate, and the Greater Contractive will make that Force of a leſs Sweet or Fiery Nature, and bring it nearer to a Sowre or a Cold; and that this is the Caſe of Oil and the Juice of Sloes is pretty Evident, ſince the Firſt is Inflammable, and the Laſt the Contrary.

Smells and the ſeveral Kinds of them ſolved from the above-ſaid Principles.
Princip. of Natur. Philoſ. Chap. 10. Part 1.

§. 12. The next Accidental Property of Matter is that of Smells, which likewiſe may be much Better Accounted for, from theſe Contractive and Expanſive Forces, than from any Imaginary Effluviums whatſoever, the Abſurdity of which in the Firſt Part of the *Principles* of *Philoſophy*, I have Endeavoured to ſhew; For if there is an Expanſive Force in Bodies, and that in Various Degrees, where that Expanſive Force is kept down to the Surface or Space, in which it Exiſts, by a Superior Contractive, there will no Smell Enſue, and this is the Caſe of Metals and Minerals. But where the Expanſive Force is Superior to the Contractive, as in Spirituous Bodies or Fermenting ones, and in Vegetables, Smells are Produced; for by their Brisk and Lively Action upon the Æther, from their Expanſive Force in Conjunction with their Contractive, they ſpread their Impreſſion round them, without any Diminution of their Parts by Effluviums, and are always prepared to Excite the ſame Senſations in us. Thus alſo, where the Contractive is Superior to the Expanſive, if yet the Expanſive is Vigorous and Quick in it's Action, Smells may be Excited in us, as in Odorous Woods, and other Solid Bodies, which ſend a Perfume from them.

Why Water and Fire have no Smell, and yet why both of Them have, if Joined, the Firſt with an Expanſive Force, and the Laſt with a Contractive.

But in Water, where the Contractive and Expanſive ſeem to be in an Exact Æquilibrium, and in Fire, where the Expanſive has little and an almoſt Imperceptible Contractive Join'd with it, as well as before in Solids, which have little and an almoſt Imperceptible Expanſive, we do not Experience any Smells. And yet, if by Fermentation an Expanſive Force is added to Water, or to Metals, or to Minerals, or if to Fire a Contractive, Smells are Produced; Thus Stagnant Waters by being Agitated by the Rays of the Sun, and Metals and Minerals, by their Diſſolution in Spirit of Nitre, become Fœtid, and any Thing burnt in the Focus of a Lens does alſo Emitt a Smell Agreeable to the Subſtance, which is Inflamed. From all which it is manifeſt, that there muſt be a Great Degree of the Expanſive Force, and that it muſt be Join'd with a Good Degree of the Contractive, to produce the Senſation of Smell in us.

The Reaſon of which is Evident, becauſe an Entirely Contractive, it is Plain, cannot do it; nor an Entirely Expanſive, without a ſufficient Force of the Contractive, to Moderate and Allay the Violence of it; becauſe otherwiſe it would not Affect our Organs of Smelling in a Certain Degree Requiſite for that Senſation, but would Confound and Diſorder them by it's Exceeding Expanſiveneſs and Volatility; And an Expanſive and Contractive in an Æquilibrium, as in Water, cannot Exert it ſelf enough outwards.

Smells either Fragrant, or Fœtid, or Intermediate to both.

Smells may be Diſtinguiſh'd into Fragrant and into Fœtid, or Pleaſing and Offenſive, with the ſeveral Intermediate Degrees of them.

From whence Fragrancy.

Fragrancy or Perfume is owing to a Greater Degree of the Expanſive Force, in Conjunction with a Leſs Degree of the Contractive, by which it Acts upon the Æther, and by it upon our Noſtrils; And from hence it is, that moſt Flowers have an Agreeable Smell to us, and if Bruſh'd, by which their Expanſive Force is Gently Rais'd and Excited, that Fragrancy becomes Stronger and more Vivid; Thus Steel or the String of an Harp, when ſtruck, is thrown into a Multitude of Vibrations.

From hence likewiſe in the Spring, when the Graſs and Flowers are Young and Vigorous, and their Expanſive Force Active and Lively, and when the Air is in it's Freſheſt Temper, and it's Elaſticity Strong, by a mutual Acting upon one another, there is a peculiar Fragrancy Raiſed, and the Whole Air ſeems to be Perfumed by it.

From the ſame Cauſe are produced all thoſe Delightful Smells, which we meet with in the Fields, in the Summer Time, or in the Harveſt, namely, from the Expanſive Force of the Bloſſoms, of Corn and Fruits, with which we are every where Entertained, and from the Expanſive Force of the Æther and the Sun's Rays, eſpecially, when Attended with ſome Moiſture or a Contractive Force, according to what has been already Mentioned.

Thus alſo in Woods and Spices, which grow in Hot Countries, ſuch as Cedar, Cinnamon, Cloves, Mace, and in Fruits, ſuch as Lemons, Oranges, Citrons, and the like, there is a Peculiar Fragrancy, upon Account of the Expanſive Force Impreſs'd upon them from the Extraordinary Heat of the Sun in thoſe Climates, with which they continually Act againſt the Contractive Forces in their Sowre Juices, by which they are detained, and upon the leaſt Friction or Rubbing, the Expanſive Force Raiſes and Exerts it ſelf into Action, and thereby Excites the Pleaſing Senſations we Receive from thoſe Bodies.

Rohault. Phyſic. Chap. 25. §. 12. Lib. 1.

Lastly, A Purulent Matter, produced from the Beaver, at Firſt has a Fœtid and Diſagreeable Smell, but being for ſome Time Expoſed in the Heat of the Sun's Rays, it at length Changes to a Tolerable one, and afterwards is Endued with a moſt Extraordinary Fragrancy, which cannot be owing to any Thing, excepting the Expanſive Force Impreſs'd upon it from the Sun's Action, and this is what is called Musk, and is of much the ſame kind with Civet. Amber-Greaſe is ſuppoſed to be Formed from the Excrement of the Sea, which it throws off and ſeparates from it ſelf by it's Exceeding Working and Fermentation, and probably has therefore at Firſt a Stinking and Loathſome Smell, as other Water has upon a like Emergence of it's more Corrupted Parts, but afterwards, by being Envigorated from the Heat of the Sun's Rays, it Acquires in all likelihood an Expanſive Force, from whence it's Fragrancy is Derived.

From whence a Fœtor.

And, as we have made a Fragrancy of Smell to Proceed from a Greater Degree of the Expanſive Force, Acting with a Leſs Degree of the Contractive, ſo it is Reaſonable to Think, that a Fœtor, or Loathſomeneſs of it, muſt be owing to a Greater Degree of the Contractive Actuated by a Leſs Degree of the Expanſive.

Thus in the ſeveral Caſes now Recited, if Flowers, or Bloſſoms, or Fruits, which before were Fragrant, or Spices and Odorous Woods, are Bruiſed or Beaten, and Pounded to a Good Degree, by which their Spring and Elaſticity, or Expanſive Force is Diminiſh'd and Broken, and their Contractive more obtains, they loſe their Delicate Perfume, and ſometimes change into a Smell, which is Diſagreeable and Offenſive; And in Musk, whilſt the Contractive Prevails in it's Purulency, and is Excited by a Small Expanſive, the Smell is Stinking and Nauſeous, as is even that of Flowers, as Poppies, when they are of a Soporifick, Cold, and Contractive Nature.

'Tis alſo Manifeſt, that Spirit and Oil of Vitriol, which Conſiſt of a Strong Contractive, Excited by an Expanſive, produce a Fœtid Smell, as do likewiſe Metals, Lead, eſpecially, when in Fuſion, the like do Salt-Petre, and Gun-powder, which is made of it, when Agitated by the Expanſive, and Glue when Heated, all which in their own Nature have a ſufficient Degree of the Contractive Force belonging to them, and ſend forth a moſt Fœtid Smell; And Moſt Solid and Combuſtible Subſtances, the more they have of the Contractive, are the more Offenſive in the Smell, which they Emit.

THE Contractive Force of Hair, or of Wool, which are made from thoſe Juices of Animals, which have the utmoſt Phlegm and Tenacity in them, when Excited by the Expanſive Force of Fire, as a Tough Phlegm in General Raiſed into Action the ſame way, will create a moſt Nauſeous Smell from the Expanſive Force Communicated to them; Pit-Coal, which has a leſs Contractive Force, will create a leſs Nauſeous one, as having more of the Oil, Sulphur, and Inflammable, or Expanſive, and leſs of the Phlegm and the Contractive; Wood, as having ſomething of the Expanſive Force of the Vegetable, will create a ſtill leſs Nauſeous Smell to us upon it's being Inflam'd; and Straw or Stubble, which has ſtill leſs of the Contractive, the leaſt of all.

THE Smells, which I have hitherto taken Notice of, are ſuch, which all or the Generality Agree to be Fragrant, or Fœtid, and which ſeem, the one to Pleaſe and Rejoyce the Mind, and the other to be Nauſeous and Offenſive to it; Becauſe the Expanſive and Contractive Forces of the Mind have ſuch a Certain Degree, to which the Firſt are more Suited and Adapted, and the Laſt of too Phlegmatick and Contractive a Temper for it to Reliſh, or Like it's Impreſſions.

As to other Smells, which Ariſe from Intermediate Forces of Expanſion and Contraction, they are Approved or Rejected by the Mind, according to the Various Proportions of the Expanſive and Contractive, which belong to it.

THUS, as in Taſts, ſo likewiſe in Smells, and even in Perfumes, thoſe which are Pleaſing to Minds, which have a certain kind of Delicacy from the Expanſive Force of them, ſhall be hateful to others, which have a more Robuſt Expanſive, that is, which Conſiſts of a Greater Degree of the Contractive join'd with a Strong Expanſive, to which more Rancid Smells ſhall be the Better Perfume; which ſeem to be the Two Caſes of an Elegant and a Polite Perſon, and whoſe Parts are Fine and Expanſive, and of a Plain and Hardy Soldier, whoſe Genius is Great, Commanding and Diffuſive, from the Expanſive Force of his Mind, and Solid, and Grave, and Serious from the Contraction of it; The Firſt of which Tempers cannot be better Repreſented than by the Characters we have of the Poliſh'd Age of *Auguſtus*, and the Laſt than by thoſe of the Firſt and Antient *Romans*, who would Prefer a Leek or an Onion to all the Refined Taſts or Smells in the World.

Sounds and the Variety of them Derived from the ſame Principles.

§. 13. FROM Taſts and Smells we ſhall Proceed to Sounds, which likewiſe may be Explained from theſe Forces of Expanſion and Contraction, and the Various Degrees and Combinations of them: And in this Caſe, the Quickeſt and Livelieſt Sounds are Produced from the Greateſt Expanſive or Elaſtick Force, join'd with a Leſs Contractive, and the Dulleſt and Heavieſt from the Greateſt Contractive Force, join'd with a Leſs Expanſive.

Not from Vibration, which is only a Conſequence of the Expanſive and Contractive Forces.

LET us Firſt take thoſe Sounds, which are Termed Muſical, and it is very Evident, the Quicker the Vibration of any String in Muſick is, that is, the Stronger the Expanſive Force, and the Leſs the Contractive, the Acuter and Sharper the Sound is; and on the Contrary, the Heavier and Duller the Vibration is, the Sound is in like manner Graver; The Nature of which Sounds are not to be Aſcertain'd from the Vibrations of the Strings or the Bodies, which are ſuppos'd to Produce them, but from the Innate Force and Velocity, which each would have in one Point only; The Quicker or Slower Vibrations are only Conſequences of ſuch Innate Forces, and each of them will occaſion Like and Similar Sounds from the Beginning to the End of their Motion, as Proceeding from the ſame Cauſes, namely, their Peculiar and Diſtinct Forces; As to the Vibrations themſelves, they do no more than continue the Ringing or Repeating the ſame Sound in our Ears, and therefore Sound does not Conſiſt in them, tho' the Continuance of the ſame Sound does; 'tis nothing more than if a Sharp Percuſſion or an Heavier was made upon the Æther in a Point, a

Line, or a Surface, for the Producing of the Senſation of Differing Sounds in us, and the Tremulous Motion has no other Effect, than that of Repeating the ſame kind of Senſation to our Minds, which will be the ſame, tho' this Force were to Act in a Point only, or in a Longer or Shorter Vibration, and which will fully Explain that Grand Difficulty in the Theory of Sounds, how it comes to Paſs, that the Sound of the ſame Muſical String continues the ſame thro' all it's Vibrations, be they Shorter or Longer.

The Great Difficulties in the Theory of Sounds Explained.

We may here add the Reaſon, which has not been given in any Philoſophy, why an Elaſtick Force in Bodies is Attended with a Vibration upon Percuſſion, namely, becauſe ſuch a Body is Compounded of an Expanſive and Contractive Force; The Expanſive therefore being Raiſed by the Expanſive of Percuſſion Reſults to the ſtroke, and is Drawn back by the Contractive, which not being able to Retain it, it again Recoils by the Force, which the Percuſſion Excited in it, and is again Drawn back by the Contractive, the Elaſtick Medium aſſiſting in this Vibration, till the whole Force of the Original Percuſſion is ſpent, and the Expanſive and Contractive remain at Reſt in their Firſt Point or Surface.

How the Voice is Formed, and the Different Modulations of it.

From the Muſical Notes upon Strings, if we Proceed to thoſe of Voices, the ſame Expanſive and Contractive Forces will prevail in the Solution of theſe Phænomenons; For the Quicker or Brisker the Air or Æther is ſtruck, not by the Epiglottis, which continues always open, for our Conſtant Breathing, excepting when any Thing is Conveigh'd over it into the Stomach, in which Caſe it Cloſes, but by the Muſcular and Animal, and Elaſtick Motion of the Lungs, and the *Aſperia Arteria*, Derived from the Expanſive of the Mind, the Shriller and Sharper the Voice is.

So we find it, when there is the Extremeſt Emotion in the Mind from any Fright or Ailment, which is brought upon it, and when it's Expanſive Force is Excited in the Greateſt Degree to Repell the Grievance, that it Exerts it ſelf upon the Muſcles, and the Rough Artery, and thoſe by the Elaſtick Force, which is Communicated to them from the Mind, Act upon the Air in the Cavity of the *Aſperia Arteria*, which occaſions the Shrieks and Screams, and the Sharpeſt Noiſes, which we hear upon ſuch Emotions.

This Exceeding Expanſive Force of the Mind joined with the Contractive Force of the Muſcles, which it Raiſes and Excites, and from them Strikes upon the Contiguous Air in the Rough Artery, is the Cauſe of the utmoſt Shrillneſs in Sounds, which we Experience: On the Contrary, where the Mind is but dully Affected, and where the Spirits are Sunk and Low, where the Activity of it is not ſo Great, and the Muſcles are not Moved by it with that Quickneſs and Vivacity, the Air, Included in the Lungs and the *Aſpera Arteria*, finds a more Languid Percuſſion, and conſequently gives a Graver and Deader Sound to the Ear, which proceeds from the Greater Power of the Contractive.

And this is the Reaſon, why Men can Fall and Raiſe their Voices at Pleaſure, and Change them into a Thouſand Different Notes, according as the Mind thinks fit to Exert more or leſs of it's Expanſive and Contractive Forces, which belong to it, and by them Act upon the Muſcles for their Expanſion or Contraction, from whence Different Velocities are Communicated to the Air, and from it to the Tympanum, by which that Variety of Sounds, which we Perceive, is produced in us.

Hence it is, that Children and Young Perſons, whoſe Spirits are Brisker and Livelier, and whoſe Expanſive Force of Mind is Gayer and Quicker, as well as that of the Muſcles, and therefore is in a Greater Proportion to the Contractive of them, in their Voices have a Shriller and Sharper Note.

But in Perſons, who are Grown up, and are more Advanced in Years, and in whom a Gravity of Thought, and a Greater Contractive Force obtains both in the Mind, and in the Muſcles, in Proportion to the Expanſive, by which Means the Air is ſtruck by the Organs of the Voice with a more Solid, but a leſs Elaſtick Force, a Graver Tone prevails; Another and a Concurrent Cauſe of the Difference in Voices is the Narrowneſs or Wideneſs, that is, the Contraction or Expanſion of the Larynx by the Muſcles of it. For which Reaſons alſo Women have Voices, which are Generally Shriller than Men's are.

Why ſome Sounds are Muſical and others not.

From the ſame Principles may the Cauſe be Derived, wherefore ſome Sounds are Harſh and Unpleaſing to us, and others Harmonious and Muſical; For if the Expanſive or Contractive Force, whether in Vocal or Inſtrumental Sounds, is Strained to an unnatural Degree it Produces Sounds, which are Diſagreeable, but if it is Exerted within certain Limits, ſo as not to Proceed from a Violence upon our Natures, nor ſo as to offer a Violence to them, ſuch an Expanſive or Contractive Force occaſions Sounds, which are Harmony and Muſick to us.

THUS a Shriek or a Scream, which Proceeds from too Great and Violent an Agitation from the Expanſive, and an Hoarſeneſs, which Proceeds from too Great a Degree of the Contractive, as in Colds, which are owing to an Exceſs of the Contractive, Produce Sounds, which are not Pleaſing to us; And the ſame may be ſaid of the Strings in Muſick, where the one has a ſqueaking Sound from too Great an Expanſive Excited in it, and the other an Hoarſe Baſs from too Great a Contractive.

FROM the like Methods of Reaſoning we alſo know, that where Perſons have a Greater Contractive Force in their Minds, and in their Muſcles, the Inſtruments of their Motion, The Baſs is more Agreeable to them; and thus we find in Experience, that thoſe, who are more Grave and Tragical in their Thoughts, are more Pleaſed and Delighted with ſuch Muſick; And on the Contrary, thoſe, who are more Briſk and Airy, and have more of the Expanſive in their Minds, like the Quicker and Briſker Sounds much Better. We muſt farther Obſerve, that thoſe Sounds are likewiſe Eſteem'd Muſical by us, which Approach the neareſt to Human Voices, or the Modulations of them, as being Naturally Delighted moſt with what Agrees with, or Comes neareſt to, our own Species, and for the ſame Reaſon, Vocal Muſick has Generally the Preference with us to Inſtrumental; Thus, the Barking of a Dog, or the Roaring of a Lion, was never thought to be very Harmonious, but the Notes of Birds Extremely ſo.

Why there is a Sympathy in Uniſons.

From hence alſo it is Plain, why there is a Sympathy in Uniſons, ſo that upon the Striking of the one, the other Trembles; For upon the Percuſſion of the Uniſon, It, by it's Natural and by it's Innate Force of Expanſion joined with the Contractive, which it Excites, Reſults to that Percuſſion, by which means there is an Impreſſion made upon the Air or Æther, which likewiſe, having a Certain Degree of the Expanſive and Contractive Force, Reſults or Recoils upon the Uniſon, and this Reciprocal Percuſſion of the Uniſon upon the Air or Æther, and of the Air or Æther upon the Uniſon, is the Cauſe of that Particular Vibration we Perceive, and which Vibration will continue, till the Original Force Impreſs'd upon the Uniſon, from the Expanſive Force of the Mind, and of the Muſcles, which it makes uſe of in ſuch a Percuſſion, is ſpent: For, if we conſider exactly, how can it be Imagin'd, that any other Effect ſhould proceed from the Percuſſion of the Uniſon, unleſs the Reſult of it peculiar to that Innate Degree of Expanſion or Elaſticity, which it has, againſt which the Contractive Force of the String, and of the Centers of the String's Tenſion Re-acts? This Contention betwixt the Expanſive and Contractive Force of the Uniſon Raiſes a like Conteſt in the Expanſive and Contractive Forces of the Air or Æther about it, ſince the Air or Æther is ſo Formed and Diſpoſed, as to be ſuſceptible of any Impreſſions, from whence it becomes Expanſive by Heat and Contractive by Cold, and according to the Various Actions it Receives and Conveys, Odorous, Coloured, and Sonorous.

THIS therefore being Allowed, as it ſeems to be Certain, it is Evident, that when the Air or Æther around has the ſame Percuſſion given to it by the Uniſon, which is plain from our Hearing the Sound of it every Way, the like Effect will be Produced by the Air's Acting upon another Uniſon, which has the ſame Degree of the Expanſive and Contractive Force with that, which it Receives from the Former. But this Reciprocal Percuſſion of the Uniſon and Air or Æther, being of a Peculiar Force, Compounded of one Particular Degree of the Expanſive and Contractive; From hence it is, that it Affects by it's Motion no other String, but what has the ſame Expanſive and Contractive Force with it.

Why Sound is Stronger when Impreſs'd upon a Thicker Medium than upon a Thinner.

WE may likewiſe from theſe Principles give an Account, why in General Sound is Stronger, when Impreſs'd upon a Thicker Medium of Air or Æther, and Diminiſh'd, when Impreſs'd upon a Thinner; Becauſe the Expanſive and Contractive Force of the Air or Æther, is in the Former Caſe thereby Increas'd, and in the Latter Impaired and Leſſen'd; for in the Former Caſe, the Expanſive Force is Increas'd, by the Increaſe of it's Elaſticity, and the Contractive, by it's Compreſſion and Denſity, but where the ſame Percuſſion is made upon a Greater Expanſive and Contractive Force, the Sound will be the Greater; Thus, if we ſtrike upon a Solid Body with the ſame Force, as we do upon Wool or a Feather, the Sound will be much Greater in the Firſt Inſtance, than in the Laſt.

Why Increas'd in the Speaking Trumpet.

From hence farther is Manifeſt, the Reaſon why the Sound is Increas'd in the Speaking Trumpet, as it is in any Inſtrument of Vocal Muſick whatſoever; becauſe the Percuſſion of the Voice is made, not upon mere Air or Æther, but upon Bodies, which have a Greater Degree of the Expanſive and Contractive, by which means, the Sound becomes more Solid and Strong; and the more Parts are Affected, and Struck, which will be the Larger the Cavity is, the Greater will be the Sound, that is, if the Cavity is not ſo Large, as that the Force of the Voice cannot reach it with it's full Strength and Vigour.

Whence the Ringing Noiſe in Choirs of old Cathedrals.

From this Percuſſion of the Voice upon Elaſtick Bodies, Proceeds the Ringing and Ecchoing Noiſes, we always find in Choirs, eſpecially in Cathedrals, which are Antient, and whoſe very Walls and Roofs have Acquired from the Air, by a Long Tract of Time, a more Peculiar Rigidneſs and Elaſticity, for in New Buildings, we do not Experience the ſame Sonorouſneſs.

Farther, The Propagation of Sound is likewiſe Explained from this Doctrine, and the Immediate Ceaſing of it, at a Nearer or Greater Diſtance from the Sonorous Body, upon the Vibration of it Ceaſing.

How Sound is Propagated.

The Firſt is Explicated from this Plain Axiom, that where there is a Percuſſion upon Air or Æther every way, as there is from the Sonorous Body, which Trembles and Vibrates, not from a Line, or an Axis, but from a Center every way, that Air or Æther will ſtrike that which is Contiguous to it, which likewiſe will Vibrate every way, and Communicate it's Impreſſions all around, to a certain Diſtance, where the Force is Spent and Loſt; which Diſtance is More or Leſs, according to the Force and Strength of the Percuſſion, which Depends upon the Proportion, which there is of the Expanſive and Contractive in the Sonorous Body; thus the Sound of a Bell will be heard Farther than an Harp or a Violin, becauſe there is a Greater Degree of the Expanſive and Contractive, in the Former Caſe, than in the Latter.

From hence alſo Sound may be Propagated thro' a Solid Body, becauſe Percuſſion may be, and the ſtriking of one Part upon another, in the ſame Way and Manner, as in Air or Æther.

The Laſt is alſo Evident, becauſe where Percuſſion, which is the Cauſe of Sound Ceaſes, the Effect, which is Sound, will Ceaſe at the ſame Time.

Concerning Sounds, which are not Muſical.

Thus far we have conſidered Sounds, which are Term'd Muſical, and have Endeavoured to ſhew how they are Derived from the Expanſive and Contractive Forces of Matter; We ſhall now Proceed to other Sounds, and from them Demonſtrate ſtill farther the Truth of this Doctrine.

Why Fire or Flame does not Produce Sound, nor the Percuſſion of Solid Bodies upon Æther, nor the Motion of the Hand in Air.

And Firſt, where there is a Great Expanſive Force, and a Small Degree of the Contractive, there is no Sound Produced, as in the Rays of the Sun, the Flame of Fire, a Lamp, or a Candle, the Reaſon of which is, becauſe there is no Reſiſtance made to ſuch Percuſſions, the Air or Æther on the Contrary Joins with, and Aſſiſts and Promotes theſe Actions.

On the other Hand, where there is a Great Degree of the Contractive, as in Solid Bodies no Sound is Conſequent, becauſe the Air or Æther has a Preſſure, as well as an Elaſticity, by which it Concurrs with the Contractive Force of them.

And why Sound is Produced by Water or Fuel thrown upon Fire.

But if a Contractive Force, as Water, or a Solid Body, as Fuel, is thrown upon Fire, a Sound is Produc'd, becauſe their Actions do not Concurr, but there is a Reciprocal Percuſſion upon each other, and a mutual Reſiſtance.

From hence it is, that if we Move our Hand in Air no Sound Ariſes, becauſe there is no ſenſible Reſiſtance to the Motion of it, but if we Strike the Air or Æther with an Expanſive Force, Joined with a Contractive, to which it Reſiſts, as in the Caſe of a Switch or a Wand, a Sound Enſues.

From all which it is Plain, as we have before Aſſerted, that there muſt be a certain Degree of the Expanſive and Contractive, Acting upon Air or Æther, to Produce the Senſation of Sound in us.

Or by the Exploſion of Gun-Powder.

WHICH is farther Confirmed from what is Experienc'd in the Exploſion of Gun-Powder, which Striking upon the Air or Æther, with the Expanſive Force of Fire Joined with the Contractive of Nitre, is Reſiſted by it, and by that Percuſſion, which always ſuppoſes a Reſiſtance or Re-action to the Percuſſion, the Mind comes to be Informed of the Contraſt there is betwixt them, by the Sound Produced from ſuch Action or Re-action, but the Sound is Small, as the Reſiſtance is ſo, when the Exploſion of Gun-Powder is made in Open Air.

ON the Contrary, when the ſame Expanſive and Contractive Force is Included in a Cannon, or a Mortar, or in a Rock, the Prodigious Expanſive Force of the Gun-Powder, Joined with the Small Contractive of it, Striking againſt the Vaſt Contractive and the Small Expanſive Force of the Canon or Mortar, or the Rock, there is the Greateſt Oppoſition, which is Poſſible, betwixt theſe Forces, and conſequently the Greateſt Sound is Produced from them, becauſe the Force of Percuſſion is the Greateſt.

MOREOVER the Small and Gentle, tho' Quick and Lively Percuſſions of the Strings of an Harp, would not Produce Sound, unleſs they ſtruck upon the Air or Æther in Various Degrees, and were variouſly Reſiſted by it; for if the Air or Æther was entirely Obedient to the Impreſſions of theſe Elaſtick Strings, and did not Recoil and Reſult upon them, there could be no more Sound from them, than there is from the Flame of a Lamp or a Candle.

Or by Percuſſion upon a Solid Body.

THUS alſo in Hard and Conſiſtent Bodies, what is the Reaſon that we hear a Sound upon the Percuſſion of them? Unleſs that the Expanſive Force of the Percuſſion, Derived from the Expanſive Force of the Mind, Raiſes the Expanſive Force of the Solid Body, which before lay Dormant by the Superior Contractive, which Oppreſs'd it, and thereby Exerts it ſelf more Strongly and Powerfully upon the Air or Æther, which again Recoils upon it, and at the ſame time Strikes the Tympanum of the Ear by it's Elaſticity, and Informs the Mind from thence of the Struggle or Competition, which it has with the Percuſſion Derived from it; for if the Expanſive Force of the Body only ſtruck the Air or Æther, as it does in Colour, without a Reſiſtance from it, the Cauſe of Sound and Colour would be much the ſame, which it is plain they are not, ſince there may be a very Lively Colour, as in Flame, where yet there is no Sound which accompanys it; And that the Expanſive of the Air or Æther, upon the Percuſſion of the Body, muſt likewiſe Act by it's Elaſtick Force both ways is Evident, becauſe otherwiſe no Impreſſion could be Communicated to the Ear; And this Doctrine is Confirmed in Fact, ſince we find that any Elaſtick Force, as that of the String of an Harp, or the Tone of a Bell, which does Communicate Sound, does Vibrate and Tremble, and Imparts it's Percuſſions all the ways, which are Imaginable.

FROM hence it is, that if we Strike a more Elaſtick Body, as a Stone, or a Marble, it will Reſult upon the Air or Æther more ſtrongly from that Percuſſion, and conſequently cauſe a Brisker or Livelier Sound to us, than if the ſame Force of Percuſſion is given to a Leſs Elaſtick Body, as Lead, which Produces to us a Flatter and a Deader; Steel upon Percuſſion Recoils more ſtrongly than Iron, Silver than Gold, Metals than Stone, and Stone than Clay or Earth, for the ſame Reaſon; and conſequently, the one Produce Sounds more Quick and Alert than thoſe of the other; And even in the Animal World, Noiſes are Produced from Mutual Quarrels and Conteſts, and Silence from Acquieſcence.

THUS alſo, if Percuſſions are made with Different Forces upon the ſame Body, the Greater the Expanſive Force of Percuſſion is, the Greater will be the Expanſive of the Body upon Air or Æther, it will be ſo much the more Excited and Raiſed into Action, and by Conſequence will occaſion a ſtronger Sound to our Senſation; For, if we Strike a Stone or a Marble with a Leſs Force of Percuſſion, it will Produce a Leſs Sound, and if with a Greater, a more Intenſe one, and the ſame obtains in Lead, or in any other Bodies.

Light and Colours ſolved from the ſame Principles; The Firſt of which is by a Percuſſion of

§. 14. FROM Sounds if we Proceed to Light and Colours, and the Refractions and Reflexions of them, we ſhall find, that the Expanſive and Contractive do here likewiſe Prevail, and that they are Entirely derived from theſe Forces.

LIGHT, as that of the Sun, of Fire, of the Flame of a Lamp or a Candle, is manifeſtly owing to the Expanſive Force of thoſe Luminous Bodies, which, Striking upon Air or Æther, Produce the Senſations of a Vivid Yellow, or Orange in us; By Air or Æther, I here, and all along, mean a certain ſubtile Medium, which is ſuſceptible of theſe Various Percuſſions from Bodies, and of which all the World is Full, which is Endued with a Degree of Action and Elaſticity, by which it Communicates the Impreſſions, made upon it, to our Senſations, from the moſt Diſtant Parts of the Univerſe.

the Expanſive Force of the Luminous Body upon the Æthereal Medium.

THO' this Medium is Alter'd and Changed in it's Force by other Forces, which Mix with it, eſpecially near the Sun, or the fixt Stars, the Earth, or the Planets, and the Various Comets, which belong to our or any other Solar Syſtem; which Forces, which mix with it, are Different, according to the Different Expanſive and Contractive Forces, of which the Sun, or the Star, or the Planet, or the Comet, is Compounded; From which Diverſe and Sundry Mixtures their ſeveral Atmoſpheres are Formed.

THUS the Atmoſphere about the Sun muſt be of an Exceeding Expanſive Nature, and that about our Earth, in Compariſon with it, of a more Sullen, Heavy, and Contractive, and as to the Moon, it ſeems to have None at all; That Body being in all Probability nothing more than a Vaſt and Stupendous Rock, Mountainous and Craggy, Placed near the Earth, by the Great and All-wiſe Creator, for the Reflexion of Light, the Raiſing of Tides, and it's Drawing forth of Plants and Vegetables, by it's Contractive Force in Conjunction with the Expanſive of the Sun, and for a Source of Froſt and Cold, or the Contractive, as the Sun is of Heat and the Expanſive; and which ſeems to be the Deſign of the ſame Infinitely Intelligent Being, in Reſpect of *Saturn*'s Ring, and His, and *Jupiter*'s, *Satellites*, and all thoſe, which are called Secondary Planets, with Regard to their Primary.

See Book 1. Chap. 5. §. 21.

BUT allowing for the Variety of Atmoſpheres, Ariſing from the Different Natures of the Bodies, which they Surround, it is Reaſonable to think, that the whole Univerſe is filled with one Uniform Active Medium, Ordained and Produced by the Expanſive Force of the Infinite Mind, which Medium is capable of Tranſmitting the Actions of one Body to another, tho' at an Immenſe Diſtance.

FOR how can any one Conceive, that Bodies ſhould Act upon one another by Percuſſion, which is the Preſent Caſe, without any thing to Conduct or Convey the Action? We may as well Affirm, that we can See, or Hear, or Taſt, or Smell, without any Impreſſion made upon our Organs of Senſation, as that any Percuſſion ſhould be Communicated from one Body to another, without a Medium to Tranſmit the Force which is Impreſs'd.

IN Anſwer to this it is Affirmed, that Light is a Body, and that it is Emitted from the Sun, and Arrives to us in 7 or 8 Minutes of Time, from Obſervations made upon the Eclipſes of *Jupiter*'s *Satellites*, and that it always is Propagated in a Direct Line, all which are ſuppoſed to be Arguments, that Light does not Proceed from a Percuſſion upon a Medium, but from an Emanation of it from the Luminous Subſtance; Becauſe, if it was by a Percuſſion upon the Medium, Light, conſidered in it ſelf, would not be a Body, nor would it be Emitted from the Sun, nor, as it is Apprehended, would it come to us in a certain Proportion of Time, but in an Inſtant, nor would it be Propagated in a Direct Line, but would be Diffuſed into all the Parts of the Medium, upon which the Impreſſion is made; In Refutation of which we ſay,

Sir Iſ. Newt. Opticks.
Molyneux's Dioptricks.

FIRST, That Light may have ſeveral of the Properties, which belong to Body, if it is Produc'd by a Percuſſion of the Expanſive Force of the Sun upon the Medium, which is Spread and Extended thro' the whole Univerſe, is Confeſſed; Becauſe the Medium, which is Excited by ſuch an Expanſive Force, is Body, and is Endued with the Various Properties and Affections of it, and Light in this Caſe is the Medium thus Excited.

Light not Proved to be an Emanation of Particles from the Luminous Body.

SECOND, Light is alſo Emitted from the Sun, by it's being Derived from and Owing to the Percuſſion of it's Expanſive Force upon ſuch a Medium, by which it is Propagated to all the Parts of it's Syſtem; But to ſuppoſe Light to be an Emanation of the Particles of the Sun, thro' a Void Space, and that thoſe Particles are carry'd with that Exceeding Velocity, as to come from thence to us in 7 or 8 Minutes of Time, is ſomething Incredible, and has many Difficulties Attending it.

For Firſt, in ſeveral Thouſand Years, by ſuch a Vaſt and Continual Efflux of Parts in every Minute, it would be Impoſſible, that the whole Body of the Sun ſhould not be entirely Waſted and Conſumed, and if all the Comets in the World were to Fall into it, as no Body knows, that ever any one did, it would not be a ſufficient Aliment for ſuch a Prodigious Expence of it's Particles, as ſhould every Minute and every Inſtant ſucceſſively Fill the whole Orb of the Solar Syſtem, and perhaps ſeveral Millions of Miles beyond it.

Besides, What becomes of theſe Particles? Here is in ſome Thouſands of Years, in all Probability as many Particles ſent out from the Sun, as would Conſtitute a Maſs a Million or Ten Hundred Million Times Bigger than the whole Body of it, and yet no one can tell, where they are Lodged; not in the Air or Æther, for there is no ſenſible Increaſe of it's Denſity, nor in the Earth, the Moon, or the Planets, or fixt Stars, which we do not find Receive any Material Augmentation to their Bulk; So that in this Way of Philoſophy, there are Millions and Millions of Particles of Matter, and even of whole Suns, are Spent and Exhauſted by Light, and no Mortal can ſay, where they are, or give any more Account of them, than if they had Really and Entirely Vaniſh'd.

Moreover, For any Particles of Matter to be carry'd, ſeveral Millions of Miles, by a Local Motion, in 7 or 8 Minutes of Time, is ſo Contrary to all the Phænomenons of Nature, that to mention it only is to Explode it; And ſuch an Aſſertion only Proceeds from this Philoſophy's maintaining a Vacuum, which could never Inform us of ſuch a Being, as the Sun, unleſs it ſent it's Emiſſaries ſo many Millions of Miles in every Inſtant of Time to Tell us of it; For we do not Experience or Know of any ſuch or the like Velocities in Being. And here I muſt ſay, that the Greateſt Effects in Nature are Produced by Silent and Unheeded Cauſes, and we may, I believe, Affirm, that, in General, the Reaſon, why we Underſtand ſo little of Nature is, becauſe we are apt to Attribute every Effect to ſome Extraordinary Violence, made uſe of to Produce it, whereas Nature Acts by Gentle Methods, and almoſt, many Times, Undiſcernible and Imperceptible ones to us, and that muſt be the trueſt Philoſophy, which Explains it in that Way.

Farther, ſuch a Number of Particles, be they as Small, as this Philoſophy can Imagine them, if yet they are Particles of Matter, Actuated with the ſuppoſed Velocity, would, like a Rapid and Violent Stream, bear down all before them, and we ſhould not be Heated, but Knockt down by the Rays of the Sun.

Thus even in the Infinitely ſmaller Velocity of a Canon Ball, it is ſaid, if it comes near to us, we are Affected very ſenſibly by the Motion, which it Impreſſes upon the Air, or Æther, or Medium, which Surrounds us, and it is very Evident, that we are ſcarcely able to ſtand againſt Violent and Tempeſtuous Winds, As to whoſe Particles, tho' perhaps they may be Groſſer, according to the Corpuſcular Philoſophy, yet their Velocity and Force is not a Millionth-Millionth Part of what is Attributed to the Particles of the Sun by the ſame Philoſophy.

Third, But if we only allow, that there is a Percuſſion of the Medium by the Expanſive Force of the Sun, ſuch a Percuſſion may be Communicated by it in 7 or 8 Minutes of Time; Becauſe we in Fact find, that Sound, which is own'd to be from Vibration, and therefore from Percuſſion, is Propagated with a Great Velocity without any Rapid Motion of Parts, as is Evident in Eccho's, in which we hear the Return of the Sound, almoſt as ſoon as it is Produced by Percuſſion upon the Sonorous Body, without any Violent Agitation of Parts in Air or in Æther; but the Expanſive Force of Fire or Flame being ſtill Quicker, and to which there is little or no Reſiſtance given from Air or Æther, or from the ſame Medium, thro' which Sound is Promoted, to which there is a Reſiſtance given, the Percuſſion of it is Communicated thro' it with an Exceeding Greater Velocity, ſo far, that we are ſuppoſed to ſee Light, as ſoon as it is Produced in Lightening or in the Flaſh of Gun-Powder, tho' we hear the Sound of Thunder, or the Report of a Cannon, Later.

Light may be variouſly Propagated, where the Expanſive Force of the Luminous Body

But even this kind of Percuſſion, namely, that of Fire or Flame, may be Different, as in it's Force, ſo in the Propagation of it thro' the ſame Medium, or where the Percuſſion has the ſame Force, as that of the Sun, and the Medium is Different, the Propagation of it may upon that Account be likewiſe Different; and therefore it is no Unimaginable Thing, that ſuch a Percuſſion, in ſome Caſes, may be Communicated

municated in an Inſtant, where the Expanſive Force of the Luminous Body is extremely Great, the Medium of the ſame Nature, and the Diſtance Small, thro' which it is Derived; and in other Caſes, that the ſame Percuſſion may be Communicated in Various and Different Portions of Time, as in 7 or 8 Minutes, where the Percuſſion is made from an Exceeding Expanſive Force, and is Communicated thro' Different Mediums, and where the Diſtance of the Luminous Object, as that of the Sun, is Large and Great; for if there is any Contractive Medium, which Intervenes, as that of the Earth's Atmoſphere, or any other, it will give a Check and Interruption to the Propagation of ſuch a Percuſſion, and the Largeneſs of the Diſtance, thro' which the Action is Communicated, will alſo in ſome Proportion or other Diminiſh the Force of the Action.

is the ſame, and the Mediums are Different, or where the Expanſive Force is Different and the Medium the ſame.

On the Contrary, where the Percuſſion is Different, and the Medium and Diſtance of the Luminous Object are the ſame, and much more, where the Diſtance is Different, it is Reaſonable to ſuppoſe, that Light will be Propagated to us in Different Portions and Spaces of Time; It would perhaps be hard to Evince this by Experiments, but this is Evident, that the Flame of a Lamp, or a Candle, will not Communicate it's Light to ſo Great a Diſtance, as a ſtrong Blaze of Fire, nor will a Meteor be ſeen ſo far as the Sun, the Reaſon of which can be only, that the Expanſive Force, and the Percuſſion conſequent upon it, is not ſo Vigorous in the one as in the other, and by the ſame Argument it's Propagation ſhould not.

Fourth, As to the Propagation of Light in a Direct Line, this may be acknowledged, tho' the Propagation of it was by the Percuſſion of the Sun upon the Elaſtick Medium, and not from an Emanation of any Solar Particles; becauſe a Force will be Directed and Communicated that Way, in which the Impreſſion is made.

But then on the Contrary, if Light was Produced from an Emanation of the Sun's Particles, it would be Derived in Radius's Drawn from the Sun's Body, by which means there would be a Million of Streams of Light Iſſueing in a Streight Courſe from the Sun, with as many Intermediate Spaces, to which Light would not Arrive, and by Conſequence, the Open Day would be Checquer'd with Alternate Portions of Light and Darkneſs, which is what we do not Experience.

The Rectilineal Propagation of Light, by an Emanation of Particles from the Sun, not Adequate to the Phanomenons of it, whereas a Percuſſion of the Expanſive Force upon a Medium is.

Besides which, upon the Interpoſition of a Cloud, by which theſe Streams of Light would be Intercepted, or in a Dark Chamber, where it's Ingreſs is only Permitted at a Foramen in the Window-Shut, a Perfect Darkneſs would Enſue, which again is Contrary to what every one's Obſervation will Inform him of; In all which Caſes it is Evident, that Light does Diffuſe it ſelf out of any Streight Lines Drawn from the Sun; and therefore, if an Emanation of the Sun's Particles can give no Account of this Diffuſion of Light, and Percuſſion from the Expanſive Force of it can do it, for that Reaſon alſo the one is Preferrable to the other in an Explanation of Nature, and which may be eaſily done.

For the Sun or any other Luminous Body ſtriking by it's Expanſive Force upon the Elaſtick Medium in Direct Lines, and the Medium not Reſiſting, as in Sound, but Communicating and Promoting the Force without Oppoſition, Light is by that means Propagated *in Directum*, but the Medium being Elaſtick, the Percuſſion will Excite a Vibration Side-ways, ſince Elaſticity or the Expanſive Force always Acts from a Center, as the Contractive does towards one, by which means there will be a Diffuſion of Light to every Part, and it will Spread and Enlarge it ſelf out of the Lines, thro' which the Original Communication is made.

And from hence it is, that Light is more Vivid and Strong, and has a Yellower Complexion in the Direct Rays of the Sun, and is Weaker and has a Paler Colour out of them, or in a Shade, becauſe the Firſt Proceeds from the Direct Percuſſion of the Expanſive Force of the Sun, and the Laſt from the Lateral Percuſſion of the Direct; the Latter of which muſt certainly be more Languid than the Former, and is perhaps upon an Equal Balance nearly with the Contractive of the Medium.

Why Light is Different.

There is alſo another Reaſon, why the Light is not ſo Strong in the Shade, whether of a Cloud, or of Trees, or of a Tower, or any other Body, becauſe the Light, which is Reflected from them, is Alter'd and Chang'd by the Peculiar Expanſive and Contractive Forces of thoſe Bodies; Thus the Shade of a Stone Edifice is Lighter than that of a Grove, and the Shade of a Cloud is Lighter or Darker, according to the

Why Shades of Light are Different.

the Various Compoſition of the Contractive and Expanſive Forces of the Cloud, which Cauſes it.

What Darkneſs is.

THIS therefore being the Nature of Light, we may readily Conclude, what Darkneſs is, that it is Produced, not by a bare Privation of Rays, or of the Expanſive Force, but where there is the Leaſt Expanſive Force Communicated to our Organs of Seeing, and conſequently, where the Contractive moſt Prevails; which Contractive we could not be ſenſible of, unleſs Excited by ſome Small Degree at leaſt of the Expanſive.

FOR it is Impoſſible for us to have any Poſitive Idea from a Privative Cauſe, and therefore it is, that we perceive ſeveral Degrees of Darkneſs, which could not be from one Abſolute Privation of Light, but muſt Proceed from a Greater Degree of the Contractive in the Medium, and a Leſſer of the Expanſive in ſeveral Proportions; Thus the Night is not ſo Dark, when the Moon or the Stars appear, as otherwiſe.

What Opacity and Tranſparency is.

FOR which Reaſon Bodies, which have the Greateſt Proportion of the Contractive, and the Leaſt of the Expanſive, are Opake, as Earths, Stones, Metals, and Minerals; and thoſe, which have the Greateſt Proportion of the Expanſive, and the Leaſt of the Contractive, or where the Contractive and Expanſive are almoſt Equal, are Tranſparent, as Pure Flame, and Spirituous Liquors and Fluids in General, alſo Water, Air, and Æther, where the Contractive and Expanſive are perhaps nearly Equal; Thus likewiſe Glaſs, which acquires an Exceeding Expanſive Force from the Fire, is Tranſparent; Metals, Diſſolved by it, will be Changed into Glaſs, and by Spirit of Nitre into a Tranſparent Fluid, and afterward into Chryſtals; all which Phænomenons are Evidently derived from the Expanſive Force prevailing over the Contractive, or being Equal to it nearly; for by that means, by theſe ſeveral Bodies, Acting from a Center, and not in ſo Great a Degree, or in an Equal nearly, towards one, there is a Paſſage permitted to the Rays of other Bodies thro' them; but on the Contrary, where the Contractive Force is Great, that is, where the Bodies Act towards a Center, or, which is the ſame, where the Forces of them Preſs together with more Vehemence, ſuch a Paſſage of the Rays is Interrupted, and the Body thereby becomes Opake.

THIS Doctrine is Confirmed farther from our Fingers, which are, if look'd upon in the Common Light of the Sun, Opake from the Contractive Force of our Fleſh and Skin, but if they are oppoſed to the Strong and Vivid Rays of it, they become in ſome ſort Tranſparent; becauſe the Expanſive Force of the Sun, Joining with the Expanſive Force of the Blood, Surmounts the Contractive of the Fleſh and Skin to a certain Degree, and induces that Tranſparency, which we in ſuch a Caſe Experience.

Why Melancholick Perſons are more Pleaſed with a Darker than a more Enlightened Medium.

FROM this Account of Light and Darkneſs, we may know the Reaſon, why Melancholick Perſons are more pleaſed with a Dark, a Gloomy, or a Shaded Medium, than with a more Light and Enliven'd one, and with Graver and Darker Colours, than with the more Flaſhy and Airy, becauſe the Contractive Forces of their Minds are Superior to the Expanſive of them.

Whence the Variety of Colours.

As to Colours, we have Endeavour'd to ſhew in the firſt Part of our Principles, that they are Various Degrees of the Expanſive Force, occaſioned and produced by the Tranſmiſſion of it thro' the Edges of the Priſm, that is, by the Various Contractive Forces, which it meets with, and by which it is Reſiſted and Oppoſed in ſuch a Tranſmiſſion.

THUS the Strongeſt and Livelieſt Colour, and which comes neareſt to the Complexion of the Sun's Rays, but is ſomething Darker, is a Fiery Red, and Proceeds from the Expanſive Force of the Sun being the leaſt Diminiſh'd by the Contractive of the Glaſs, as Paſſing thro' the Thinneſt Part of it, that is, thro' the Extremity of it's Edges; the Priſmatick Orange is a Weaker Red, and the Priſmatick Yellow a Weaker Orange, Green a Weaker Yellow, and Blue a Weaker Green, and Violet a Weaker Blue, and Deep Violet a Weaker Violet; all which are produced from the Expanſive Force of the Sun's Rays being variouſly Enervated by Paſſing thro' Greater Thickneſſes of the Priſm, and therefore meeting with Different Degrees of the Contractive Force of it, which in like Proportions Weakens and Impairs the Expanſive Force of them. This alſo gives an Account of that Agreeable Diverſity of Colours, which we many Times obſerve in the Clouds upon the Riſing and Setting of the

Sun, which is owing to the Different Oppoſition made to the Expanſive Force of the Solar Beams by the Different Contractive of the Clouds, and the Different Obliquity of the Rays, which Impinge upon them in a Thouſand Various Inclinations, both which Contribute to the Changeing the Expanſive Force into thoſe ſeveral Actions and Enervations of Action, from which we ſuppoſe Colours to Ariſe.

From this Doctrine it alſo follows, which we find in Fact, that the Fiery Red Rays have the Leaſt Degree of Refrangibility, that is, the Greateſt Expanſive Force, or the Greateſt Degree of Activity, Orange are the Next Leaſt Refrangible Rays, Yellow after Them, Then Green, Blue the Next, and Violet and Deep Violet are the moſt Refrangible, that is, have the Leaſt Proportion of the Expanſive Force, or the Leaſt Degree of Activity, and conſequently, are the moſt Removed from the Complexion of the Sun's Rays, and Approach the neareſt to Darkneſs.

Sir Iſ. Newt. Opticks.

Mr. Hauksbee's Exper. Pag. 29.

And upon theſe Principles, all the other Phænomenons of the Priſmatick Colours may be Explained, in which there are Various Mixtures and Combinations of them, and in which, as the Expanſive or Contractive Force more Prevails, the Colours are Brighter, or Heavier and Duller; Mr. *Hauskbee*'s Experiments do alſo abundantly Confirm this Doctrine, From which he aſſerts, That Different Sorts of Bodies afford us remarkably Different Lights, Different in Colour, and Different in Force and Vigour; which can Proceed from nothing elſe, unleſs their Various and Innate Proportions of the Expanſive and Contractive.

What Whiteneſs is. Sir Iſ. Newt. Opticks.

Hence likewiſe, when all of them are mixt together in a due Proportion, a White, not the Solar Light, which is Yellowiſh, is Produced; becauſe, there being an Equal Balance of the Contractive and Expanſive Forces, a Colour, as the Whiteneſs of Light, is Cauſed, which holds it ſelf Indifferently to all Colours; ſo that the Whiteneſs of Light is the ſame to Colour, as Tranſparency is to the Colours, with which Tranſparent Bodies are Tinged, they both Proceeding from nearly an Equal Balance of the Contractive and Expanſive Forces.

The Difference betwixt Tranſparent Coloured Bodies, and Opake ones.

From hence farther it is, that Tranſparent and Colour'd Bodies are Fluid, or of a Glaſſy Subſtance; becauſe in both thoſe Bodies either the Expanſive Prevails, or is nearly Equal with the Contractive; but where Bodies are Colour'd and Opake, the Contractive Prevails, tho' not to the Suppreſſion of the Expanſive, but to the Detaining it's Action within a Point or a Surface; whereas Spirit of Nitre, which has a Strong Expanſive Force Joined with ſome Degree of the Contractive from it's Salts, Exerts it ſelf out of a Point or a Surface, by Corroding and Diſſolving Metals by it's Expanſion, as Fire or Flame does Wood or Fuel, and Converting them into a Fluidity.

What Red, Orange, and Yellow in Fluid Bodies, Proceeds from. Sir Iſ. Newt. Opticks.

The Colour therefore of Fluid and Tranſparent Bodies Proceeds, not from the Tranſmiſſion of the Colour'd Rays, as Sir *Iſ. Newton* Affirms, but from that Particular Degree of the Expanſive Force, which is join'd with a Leſſer Degree of the Contractive, in ſuch Bodies, which Acting upon the Elaſtick Medium Produces that Senſation in us; and according as the Colour Approaches nearer to that of the Sun, which has the Greateſt Expanſive Force of any Being we know in Nature, the Greater is the Expanſive Force of ſuch a Fluid, if the Contractive Forces are Equal, which is the Caſe of Fiery Red, Orange, and Yellow.

Spirit of Nitre, Oil of Vitriol, and White or Yellow Wines, are more Expanſive than Red or Purple Wines and Fluids.

Thus we find, that Spirit of Nitre and Oil of Vitriol are of a Yellowiſh Colour, which have the Greateſt Expanſive Force of any Fluids, as is Plain from their Corroſive or Burning Quality; and thoſe, which are called White Wines, and which are of a Yellowiſh Colour, are more Expanſive, that is, are Stronger and more Intoxicating than thoſe, which are of a Deep Red or Purple, if other Things are Equal; Alſo, Sacks, Ales, and Brandies kept, are Expanſive and Yellow; On the Contrary, Rheniſh, which comes the neareſt to a White, has the leaſt Expanſive or Intoxicating Force of all, as Water likewiſe has.

It is alſo obſerved, that Red or Purple Wines are generally more liable to Produce the Stone in us, and the Yellowiſh Wines more apt to Diſſolve or to Prevent it; that the Firſt are more Aſtringent, and the Laſt in fact Looſening and Diuretick; all which are manifeſt Arguments, that the Firſt kind of Fluids have more of the Contractive, and leſs of the Expanſive Force in them, and the Laſt more of the Expanſive and leſs of the Contractive: Suitable to which, Chymiſts aſſure us, that the Red Abound in Tartar, or a Contractive Subſtance, but the White not.

'Tis alſo Evident, that the One are Sweeter and Smoother, and the other more Rigid and Harſher, which is likewiſe another Inſtance, according to what we have ſaid concerning Taſts, that the one are more Expanſive, and the other leſs ſo.

What Red, Orange, and Yellow in Solid Bodies Proceeds from.

Red, Orange, or Yellow, on the other Hand, in Solid Bodies, if of the ſame Colour with the Red, Orange, or Yellow, in Fluids, has the ſame Expanſive Force with the other, but is kept down and detained by the Superior Contractive to a Point or a Surface, in which it Acts upon the Elaſtick Medium with an Equal Force of Velocity, tho' Exerted in a Point or a Surface, with which Red, Orange, or Yellow, in a more Spirituous Subſtance, does.

Thus Clay Burnt acquires a Redneſs, and Lead Calcin'd produces Minium, which have a Great Degree of the Contractive Force, and are Endued from the Fire with a Great Proportion of the Expanſive, which yet cannot Exert it ſelf any farther than a Point or a Surface, by Reaſon of the Vaſt Contractive, which obſtructs it, ſo that from thence we only perceive the Redneſs of each Body, without any other conſiderable Effect from it.

Whence the Yellowneſs of Gold.

And the ſame may be ſaid of Gold, which by it's Yellowneſs or Orange, has the Greateſt Expanſive Force, but as from it's Weight it has the Greateſt Contractive, by that means the Expanſive is Loaded to that Degree, that it cannot Exert it ſelf, without a foreign Force to Excite it, beyond a Point or a Surface, and therefore it only Acts by it's Expanſive upon the Elaſtick Medium, and thereby Produces the Senſation of Orange or Yellow in us; Sound it cannot Impreſs upon us by ſuch an Expanſion, becauſe there is no Reſiſtance made to it, nor Smell, nor Taſt, becauſe it does not Act out of a Point or a Surface, that is, the Contractive is Superior to the Expanſive, whereas, in Taſt and Smell, the Expanſive is Superior to the Contractive.

What the Nature of Poiſons, as Spirit of Nitre, or Oil of Vitriol, which are Yellow, and White Sublimate and Arſenick.

And that Gold has a Great Proportion of the Expanſive, is Apparent, not only from it's Colour, but from what is Affirm'd, that the Leaf of it, or any Diſſolution of it, is the beſt Cordial, that is, that it has the Greateſt Expanſive Force Join'd with a Contractive, which can be agreeable to our Natures; for there may be an Expanſive Force Join'd with a Contractive ſo Extraordinary, as Spirit of Nitre, or Oil of Vitriol, which ſhall Immediately Diſſolve them, and this is the Caſe of Poiſons, which have too Great an Expanſive Force for the Contractive of our Conſtitutions; as there are others, to wit, White Sublimate, Arſenick, *&c.* which have too Great a Contractive for the Expanſive of them; What has been here ſaid of Red, Orange, and Yellow, is alſo Applicable to the Various Colours of other Bodies, making juſt Allowances for their Different Expanſive and Contractive Forces.

The Reflections and Refractions of Light, ſolved from theſe Principles.

§. 15. From the Colours of Light we ſhall now paſs on to the Refractions and Reflections of it.

How the Reflection of Light is Performed.

The Reflection of Light therefore Proceeds from the Expanſive Force of it, by which it Diſperſes it ſelf from a Lamp or the Sun, but Meeting with the Contractive Force of a Solid Body, which is Superior to it, it is hinder'd in it's Progreſs, and would there Ceaſe and Vaniſh, or elſe be Diffuſed upon the Surface of it, like Water or any other Fluid Pour'd upon the ſame Surface; and conſequently, there are Two Reaſons, which cauſe the Return of it's Rays: Firſt, It's own Native and Expanſive Energy from the Center of any Body, by which it Recoils from the Contractive, which it cannot ſubdue; Second, The Expanſive Force, which is mixt with the Contractive in every Solid Body, in a certain Proportion and Degree, and which forwards and aſſiſts the Reverberation; And as this Expanſive Force is Greater in Solid Bodies, the Rays of Light are Reflected and Repuls'd more ſtrongly. Thus Wood or Stone are not ſo Vivid in their Reflections, as Burniſh'd Metals, nor Iron or Lead ſo Active, as Steel, Becauſe they are not ſo Expanſive.

Light not always, and in General, Reflected in the ſame Angle, in which it is Incident.

It cannot therefore be affirmed in General, that Light is Reflected in the ſame Angle, in which it is Incident, ſince in Different Circumſtances of the Repelling or Luminous Body, the Reflections of Light from it may be in Different Angles; It is notorious in Fact, that we ſee the Colours of Bodies in all Angles of Reflection, tho' the Sun or Candle, which Illuminates them, is in a Perpendicular Situation to them; The Light of the Sun or a Lamp by it's Force of Expanſion Diffuſes it ſelf every way, and by the Joint Contractive and Expanſive Force of the Body is Repell'd every way, and at all Angles. From hence it is, that Light is weaken'd by Reflection, becauſe it meets with the Contrary and Duller Force of Expanſion and Contraction in Bodies, which by their Impreſſion Change and Diminiſh the Force of it.

FROM hence likewiſe it is, that Concave and Burniſh'd Metals, or Poliſh'd Glaſſes, Reflect Light to a Focus or Point, and Convex ones from one, by which means in the Firſt Caſe it is Stronger and more Collected, and in the Laſt Weaken'd and Diſpers'd.

Why Concave Metals, or Glaſſes Reflect Light to a Focus, and Convex ones to ſeveral.

BECAUSE the Contractive and Expanſive Force of the Concave Body, being Superior to the Expanſive of the Light, Repells it; and as it's Parts are in a Situation, by which it's Actions are made to Tend the ſame Way or to a Point, they accordingly Determine the Reflection of Light to one; on the Contrary in Convex Reflecting Bodies, the Expanſive and Contractive Forces in them are Superior to the Expanſive of Light, which is Repell'd by them, but as their Parts are in a Situation of Convexity, by which they Act Contrary ways, Light is alſo Repell'd to Different Points, and is thereby Diſſipated and Weaken'd. Or elſe, This may be perhaps owing to a Superiority of the Light's Expanſive Acting againſt and Reſulting from the Contractive, there of the Concave, and here of the Convex.

THE Conſequence of which is, that Objects, which are Repreſented to us in a Thicker and a more Conſtipated Light, appear Larger, and in a Thinner and more Diluted, Smaller; that the Former becomes Inflammant, and the Latter is leſs than the Natural Heat of the Sun's Rays.

Why Objects appear Larger in the Firſt Caſe and Diminiſh'd in the Laſt, and why Light is Inflammant in the one Circumſtance, and the Reverſe in the other.

AND in Plane Bodies, a middle Effect is Produc'd betwixt Both, and Light is Reflected much the ſame, as what it was when Incident; Objects are not much Increas'd or Diminiſh'd, nor the Heat of the Sun's Light, and there is no Difference betwixt the Incident and Reflected Light, excepting what Ariſes from the Expanſive and Contractive Force of the Repelling Body, by which it is in ſome Meaſure Weakened.

The Caſe of Plane Glaſſes.

ON the other Hand, the Refraction of Light Proceeds from the Superiority of the Expanſive Force of Light, above that of the Expanſive and Contractive of the Bodies, thro' which it is Refracted, by which it Forces it's Paſſage thro', inſtead of being Repell'd by them; And as in Convex ones, the Parts Act towards Different Points, the Expanſive of Light Acts in Oppoſition to them, and Collects it ſelf to one by Surmounting their Force of Diſperſing it; and in Concave Bodies, where the Parts Act towards the ſame Point, the Expanſive of Light Acts with a Contrary Direction, and Surmounting that Force of Contraction, Tends and Diſperſes it ſelf towards the Sides of the Concave, and thereby becomes Weaker; or elſe perhaps this may be owing to the Greater Force of the Glaſs, which draws the Light to a Focus in the Convex, and from one in the Concave; and from hence, as before, Light will be more Denſe and Conſtipated in the Firſt Caſe, and thereby become Inflammant, and Objects will appear Greater in it, and in the Laſt Caſe, it will be Thinner and more Diluted, and Objects appear Diminiſh'd; And in Plane Glaſſes, the Refracted Light obtains a Middle Effect betwixt both theſe.

How the Refraction of Light is Performed in General, and in Particular thro' Concave and Convex Glaſſes.

See Book 1. Chap. 5. §. 43.

HAVING gone thro' the ſeveral Eſſential and Accidental Properties of Matter, as they are Termed, we ſhall now go on to give an Explanation of the ſeveral Operations and Effects in Chymiſtry from theſe Expanſive and Contractive Forces, after we have taken Notice, that if we Admit of theſe Forces in Bodies, there will be no Occaſion for any Imaginary ſubtile Spirit, which is ſuppoſed to Pervade all Groſs Bodies, and which is Latent in them, by which their Parts attract each other, and is the Cauſe of the Coheſion of them, by which alſo Electrical Bodies are ſaid to Act, and to have a Power of Attracting and Repelling Bodies at Greater Diſtances, by which Light is Emitted, Reflected, and Refracted, and all Senſation is Excited, and Animal Motion Performed according to the Direction of the Will, namely, by the Vibrations of this ſubtile Spirit; ſince all theſe are Accounted for by theſe Real Expanſive and Contractive Forces, which are the Eſſence and Subſtratum of Matter, and from which, as we have ſhewn, all it's Properties are Derived.

Sir Iſ. Newt. Princip. Math. Lib. 3. Pag. 484. Edit. 1.

§. 16. BUT before we Proceed to Chymiſtry, we ſhall from theſe Principles give a Solution of thoſe Strange and Wonderful Phænomenons, which Ariſe from the Friction of Glaſs.

The Strange and Wonderful Phænomenons Ariſing from the Friction of Glaſs, ſolved from the ſame Principles.

LET a Glaſs Sphere be Exhauſted of it's Air, and Revolved round upon an Axis by the Motion of a Wheel, and let it be Rubbed whilſt Revolving, till it has acquired a ſufficient Heat by it's Friction; and from a Semicircular Arc, large enough to Encompaſs the Sphere, Let ſeveral Threads of Yarn hang Perpendicularly over it;

Mr. Hauksbee's Experiments, Plate 7. Pag. 191. Mr. Whiſton. & Mr. Hauksbee, Plate 6. Pag. 20,

after the Glaſs Sphere has acquired a certain Degree of Heat, the Threads will riſe from their Perpendicular Situation, and Point like ſo many Radius's to the Center of the Sphere; if the Semicircular Arc is placed under the Sphere, or if it is fixt in an Horizontal Poſition, and in both Caſes with the Concave Part towards it, the ſame Effect will be Conſequent, that is, the Threads will Riſe and Direct themſelves, like ſo many Radius's, to the Center of the Sphere.

And on the Contrary, if the Inward Cavity of the Sphere is now ſuppoſed to Communicate with the Air, and there is an Axis Inſerted into it, with a Small Circle affixt thereto, and Threads of Yarn are faſtened to the Circle; upon the Circumvolution and Friction of the Glaſs Sphere, the Threads will Riſe and Extend themſelves from the Circle, and it's Axis in ſo many Radius's Pointing towards the Spherical Surface; and whilſt the Threads are under the Influence of the Glaſs's Electricity, they may be Moved by the Finger without Touching them, and even by the Finger and Breath, thro' the Glaſs it ſelf.

Of the Friction of the Glaſs-Sphere; and the Pointing of the Threads towards it, how ſolved.

In order to ſolve which Phænomenons, it muſt be obſerved, that Glaſs has a Great Contractive Force from the Flints and Sands, of which it is Compoſed, which, tho' not the Heavieſt, are ſome of the Hardeſt and moſt Compact Subſtances; that, by their Fuſion in the Fire, a Great Degree of the Expanſive is acquired to them; that, by the Former of theſe, Glaſs is of a Cloſe and Solid Contexture, and, by the Latter, becomes Fluid in Heat, and Suſceptible of any Impreſſion, and when Cold is Brittle, it's Parts eaſily Separated, and is to a Great Degree Elaſtick and Expanſive under the Reſtriction and Conſtraint of it's Contractive; when therefore the Expanſive is Excited by Friction, it Exerts it's ſelf in Radius's from the Center, as the Actions of all Spherical and Convex Bodies do, thro' the Ambient Medium; the Threads of Yarn, which by their hanging Perpendicularly in the ſame Medium, have a Contractive or Gravitating Force, which is contrary to the Expanſive, ſuitably upon this Action of the Expanſive thro' the Medium, which was before in Æquilibrio, Exerts it's Contractive in an Oppoſite Direction to the ſame Center, from which the Expanſive Acted, to preſerve the Equal Poiſe, which the Expanſive had Diſturb'd and over Balanc'd, and which, by ſuch Tendency of a Contrary Force, is again Reduc'd to an Æquilibrium, or as near as theſe Two Acting Forces can do it.

On the other Hand, if a Circle and the Threads of Yarn affixt to it are placed within the Glaſs Sphere, and the Air Communicates with the Cavity of it, the Threads will Riſe from the Center and Extend themſelves to the Concave of the Glaſs, becauſe the Expanſive Force of it, Excited by Friction, does now Exert it ſelf Inwards, and towards the Center, as a Spherical and Concave Body does, where it's Action is Determined to the Medium, which lies within it, and by conſequence, Diſturbs the Æquilibrium of ſuch a Medium; the Contractive Force therefore of the Yarn, having a Contrary one, Diſperſes and Dilates it ſelf from a Center in the Medium ſo Affected, and obtains the Power of an Expanſive; This kind of Action of the Expanſive and Contractive, in Oppoſition to each other, has been Exemplified in the Revolutions of the Heavenly Bodies, in the Actions betwixt the Moon and the Earth, and in the Reflections and Refractions of Light, and is farther juſtified by theſe Experiments, which have been hitherto deſervedly Accounted very Surprizing. If what we have ſaid is not ſufficiently Convincing, perhaps the Suppoſition of an Expanſive Force in Yarn, which it Evidently has from Balls, which are made of it, will give us a Solution; if we will but Allow, that as the Expanſive and Contractive Act in Oppoſition to each other, ſo the Expanſive Forces Unite with and Tend to each other, and therefore the Threads of Yarn will Tend to the Expanſive of the Glaſs Excited by Friction.

From hence it is Manifeſt, that an Æquilibrium of the Air is neceſſary to theſe Phænomenons, for if the Expanſive Force of the Glaſs, and the Contractive of the Yarn were to Exert their Actions in Vacuo, where there is little or no Æquilibrium of Force to be Preſerved, they would each of them ſpend their Forces of Expanſion and Contraction by themſelves, without any Effect produced in Relation to each other.

We may likewiſe Conclude, that there is a Certain Force and Action Diſpers'd thro' the whole Univerſe, ſince otherwiſe the Expanſive Force of the Sun, and the Contractive of the Earth, Moon, and Planets, would Exert themſelves without any

Reſpect to, or Influence upon each other, unleſs there was ſuch a Medium, deſtined to Communicate their Actions, and very much in an Æquilibrium with it ſelf.

That this Refined Æquilibrium may be eaſily Diſturbed by a Finger, or a Breath, is no Wonder, or even thro' the Glaſs it ſelf, which in this Caſe acquires an Expanſive Force, and is as Permeable as the Air, which Surrounds it, tho' not to the Touch, yet as to any Forces, which may Diſturb the Æquilibrium, of which the Glaſs makes up only one Part of the Moment.

That theſe Effluvia muſt be very ſubtile is very Plain, becauſe they are none at all, all theſe Phænomena only proceeding from the Innate Forces of Bodies compared with one another, without the leaſt Diminution of their Matter or their Particles.

What I have here in General ſaid might perhaps ſatisfy the Excellent Mr. *Hauksbee*, if he were now alive, in Reſpect to ſeveral Queries, which he makes, and whoſe Obſervations and Experiments, and his Judicious Remarks upon them, deſerve to be in the Hands of all Lovers of Philoſophick Truth, who will not Reſign their Notions of Nature to the Preſent Mathematick and Abſtracted Commenters upon it.

How the Purple Light is Produced.

The Electricity of Glaſs, or the Tendency of the Threads to the Center, or to the Concave Surface of it's Sphere, requires the Air in the one Caſe or the other, but to Produce the Phænomenon of Purple Light a quite Contrary Circumſtance is Expected, that is, a Vacuum or rather a Leſſer Force in the Medium, than in Common Air; The Reaſon of which is Plain, becauſe the Expanſive Force of the Glaſs, when Excited by Friction, Acting upon a Leſs Force than that of Common Air, Raiſes it into a kind of Flame, which when a Greater Force is Introduc'd, as that of Common Air, it's Effect is Diminiſhed, and then Vaniſhes, or is Extinguiſh'd by it, as Common Flame by Water; That this Flame is a Purple one, Proceeds from the Weakneſs of the Expanſive Force of Glaſs, tho' Excited to the utmoſt Degree, and from the Contractive Force of it, which hinders it's Expanſion, according to what we have already Alledged concerning that Colour; This Purple Flame darts Inwards, as the Air is admitted, by Endeavouring with an Impetus to recede from it, as being of a Contractive Force in Reſpect of it, and for the ſame Reaſon, that Flame ſtrikes Upward.

How the Blue Sparkles, and the Crackling Noiſe are Cauſed.

The Blue Sparkles, which it Emits, ariſe from the Friction, by which the Expanſive Force of the Glaſs is ſo far raiſed, as to be Superior in ſome Minute Particles to the Contractive of it, from whence they fly off, and by the Expanſive being Increas'd the Purple is heightened into a Blue; and the Crackling Noiſe is cauſed by the Contranitency, which there is betwixt the Expanſive and Contractive, as in the Expanſive of Flame, and the Contractive of Wood, or the Expanſive of Percuſſion, and the Contractive of Glaſs, Stone, or an Anvil, or any other Contranitent Body to the Expanſive.

Why a Glaſs Cylinder becomes Electrical.

A Glaſs Cylinder, either Solid or Hollow, by Friction becomes Electrical, This is ſolved by what foregoes, and there is no Occaſion to exhauſt the Air in the laſt Caſe, becauſe it's Action is Cloſe and Compact by the Sides of the Figure lying ſo near each other, and therefore not much Interrupted by the Intervening Air, which rather complys with it, and makes it the ſame, as if a Solid one was uſed.

Why no Heat, but that of Friction will Produce this Electricity.

No other Heat, but that of Friction, will Produce this Electricity in Glaſs, becauſe by Friction it's own Proper Expanſive Force is Raiſed and Excited, whereas any other Heat Proceeds from an Expanſive Force, which is Different from it's own, and Acts not in Concurrence with, but in Oppoſition to it, and therefore rather Weakens and Impairs it.

Why this Electricity Exerts it ſelf thro' Glaſs, leſs thro' Muſlin, and not at all thro' Wood.

It will Exert it's Expanſive or Electrical Force thro' Glaſs, becauſe it has the ſame kind of Expanſive Force with it, tho' not Excited, and leſs thro' Muſlin, becauſe it is of a more Contractive and Glutinous Nature and obſtructs it's Action; and for the ſame Reaſon, if the Glaſs Cylinder lies betwixt Two Pieces of Wood, it's Electricity fails, becauſe of their Clammy, Glutinous, and Contractive Forces in Reſpect of the Quick and Elaſtick Force of the Glaſs, which is therefore Oppoſed, Vanquiſh'd, and Dampt by them.

Why it Attracts and Repells Leaf Gold, and other Small and Light Bodies, and why ſuch Bodies, when fully Repell'd, cannot be made to Touch the Glaſs, till they have been Reflected from ſome other Body.

LASTLY, It Attracts and Repells Leaf-Gold, and the like Small and Light Bodies by Turns, and when once they have been fully Repell'd, they cannot be made to Touch it, till they have been Reflected from ſome other Body.

THE Reaſon of which is, that the Expanſive Force of the Glaſs, being Raiſed and Excited by Friction, is in a kind of Conteſt with it's Contractive; when therefore the Expanſive Prevails, the Contractive of the Gold is carry'd in Oppoſition to it, as the Threads of Yarn were before, to preſerve the Equal Balance of the Medium, when the Contractive prevails the Leaf-Gold Reſults from it to the Side of the Expanſive, and will not be made to Return upon the Expanſive's Prevailing, that is, by the utmoſt Force of Electricity, becauſe it has now acquired an Expanſive Force, and therefore cannot Act in Oppoſition to it, as before, unleſs it obtains a new Contractive Force, by Touching ſome other Body, which is endued with it, after which it will again, upon the Expanſive Force Prevailing, Act with the Contractive and in Oppoſition to the Expanſive, and ſo *in Infinitum*.

FROM which it is Manifeſt, that there is not only a Contagion in our Minds, from the Company we Converſe with, of Good or Evil, of Mirth or Severity, but that it is a General Law in Nature, and that even Material Subſtances are Infected with the Expanſive or Contractive, as they Act in Concert and in Conjunction with thoſe Forces.

IT would be eaſy, from theſe Principles of the Expanſive and Contractive Forces, to ſolve, I believe, every one of the Strange and Surprizing Phænomenons Exhibited to us, from the very Ingenious Experiments of Mr. *Hauksbee*, I have only given an Inſtance of ſome, and ſhall now Proceed to the Equally Wonderful ones in Chymiſtry.

CHAP. II.

Concerning the Principal Phænomenons Obſervable in Chymiſtry.

The Preſent Method of Chymiſtry not ſuited to a Philoſophick Inquiry. Lemery, Mr. Vagani, and others.

§. 1. IT has been hitherto the Method of Authors and Teachers in this Science to Treat of Chymiſtry, as if they were Giving a Collection of Receipts, for the Compoſition of Drugs and Medicines, for the Trade of Apothecaries, and for the Uſe of the Phyſician, rather than Forming a Syſtem of Experiments for the Satiſfaction of the Philoſopher, and the Inquirer into Nature and it's Operations; and from hence it is, we find them Diſtributing their Analyſis of Bodies into that of the Mineral, the Vegetable, and the Animal Kingdom, and under thoſe ſeveral Heads to furniſh us with the Chymical Reſolution of Gold, Silver, Copper; of Guiacum, the Bark of *Peru*, Opium; or of Vipers, Urine, Honey, Hartſhorn, and the Like.

The Method propoſed more adapted to ſuch an Inquiſition.

§. 2. WHEREAS the Reverſe of ſuch a Procedure is what becomes a Philoſopher, who is not ſo much concerned to know the Particular and Artificial Manner of Analyzing theſe Bodies, as the General Effects, which Reſult from ſuch an Analyſis; the Firſt being the Buſineſs of the Operator and the Mechanick, and the Laſt of the Studious and the Inquiſitive; Conſidering this many Years ago, I had Drawn up ſeveral Papers in order to put this Science into a Different Method, from what had been Practiced by the Profeſſors of it; Namely, by Ranking and Diſpoſing their Proceſſes under thoſe General Phænomenons, in which they Terminated, as Spirits, Oils or Sulphurs, Water or Phlegm, Salts and Earth, Calcination, Chryſtallization, Precipitation, Coagulation, Condenſation, Diſſolution, Rarefaction, Pulverization, Inflammation, Diſtillation, Sublimation, Digeſtion, Extraction, and Colour; and tho' I have been Prevented in Finiſhing theſe Papers by many other Studies, which have Employed my Inquiries, it is a Satisfaction to Me to find the ſame Method Approved of, by the Learned and Ingenious Dr. *Freind*, in his *Prælectiones Chymicæ*.

The Preſent Principles of Chymiſtry Precarious and not Proved. Lemery Engliſh Edit. 3. Pag. 9.

§. 3. I Shall therefore go on in the way, which I Originally propoſed to my ſelf in the Purſuit of Nature, and Firſt conſider the Principles of Chymiſtry, which by moſt are confeſs'd to be thoſe of Spirit, Oil, Salt, Sulphur, and Earth; which yet, it is Plain, are very Imaginary ones, becauſe all Bodies cannot be Reſolved into theſe Principles; All of them are found in Animals and Vegetables, but not ſo eaſily in Minerals, and in Gold and Silver, not ſo much as one of them, of which there can be no Separation made at all.

AND on the Contrary, tho' Glaſs is made of Sand, and Aſhes or Salt, there can be no Salt Extracted from it, from whence it is Inferred, that Bodies may be Compounded of Principles, into which they cannot by any Art be Reſolved; which ſeems altogether Impoſſible; for if there were Spirit, Oil, Sulphur, and Salt of Glaſs, no doubt they would be as much found in it by the Operations of Chymiſtry, as thoſe Principles are Experienc'd to be in Animals and Vegetables; but as we never heard of any of them, ſo it muſt be Confeſs'd, that all of them are Equally wanting in the one, as they abound in the other, and that Glaſs in that Reſpect is of a like Nature with Gold or Silver; Spirit, Oil, and Sulphur, are not of ſo ſullen a Diſpoſition, as not to obey the Influences of the Quick and Active Motion of the Fire, if any ſuch were Latent in the Subſtances we have Named.

§. 4. IF yet we allow the Expanſive and Contractive Forces in Bodies, which I have been hitherto Defending, the Caſe is Plain, that as all Bodies conſiſt of theſe Two Forces in Various Degrees of them, ſo where the Expanſive Force is moſt Prevalent, as it certainly is in Animals and Vegetables if Compared with Metals, Spirit, Oil, and Sulphur, which are of an Expanſive Nature, may be Produced and Separated by the Expanſive Force of Fire, and want only the Aſſiſtance of that Force for their Formation and Exertion.

Why Glaſs and ſome Metals have none of the Chymical Principles, and Animals and Vegetables, all of them.

ON the other Hand, when, as in Glaſs, the utmoſt Expanſive Force of Fire has been uſed in it's Production, no Chymical or Analyzing Force of the Fire can alter it's Conſtitution and Diſpoſition; the Expanſive and Contractive are ſo ſtrongly united, that it will be Impoſſible to ſeparate them into Diſtinct Principles, and they will either unite with one another, as far as Poſſible in Fuſion, notwithſtanding a new Expanſive Force endeavours to diſturb them, or by Friction, when the Greateſt Conteſt is Excited betwixt them, as has been before Explained, there will be only Small Glaſſy Particles Emitted from them.

AND ſince Gold and Silver obtain the ſame Obſtinacy, we may conclude they are only more Conſtipated Glaſſes, whoſe Expanſive and Contractive Forces are Greater, and more Cloſely and Firmly united to each other, and that in all Probability they are made and formed in the Earth, by the Exceeding Heat of the Sun, or by Subterraneous Fires Mixing with, and Fuſeing of Certain Earths or Contractive Forces, which are proper for ſuch Productions, as Sand or Aſhes are Converted by a like Expanſive Force into Glaſs; Minerals are not ſo Contractive as Metals, nor ſo Expanſive as Vegetables or Animals, and therefore the Principles of Spirit, Oil, and Sulphur may be Extracted from them, more eaſily than from Metals, and more hardly than from Animals and Vegetables.

§. 5. WE have ſhewn in the foregoing Section, why ſome Bodies, which have a Greater Contractive Force, and where the Expanſive is firmly united with it, have none of the Chymical Principles, and where the Expanſive Force more Prevails, that they have all of them; we ſhall now conſider the Principles themſelves, which are Evidently Reſolved into theſe Expanſive and Contractive Forces; Spirit, Phlegm, and Oil, proceed from the Prevalence of the Expanſive Force, and Salts and Earth from the Contractive, and therefore the one may be called the Active, and the other the Paſſive; and tho' this Diſtinction is Different from what is maintained by Chymiſts, who make Spirit, Oil, and Salt to be the Active Principles, and Phlegm and Earth to be the Paſſive ones, yet the Juſtneſs of it will appear from hence, that even Spirits are acknowledged to be nothing elſe than Salts Diſſolved in Phlegm, and certainly the Diſſolvent muſt therefore be the Active Principle, and that which is Diſſolved the Paſſive; Phlegm is Fluid, and Salts not ſo, but when Diſſolved in one; And laſtly, Phlegm in Diſtillation comes before the Spirits, when they are Fixt, and after them, when they are Volatile, which ſhews that it is even more Active than ſome Spirits, tho' leſs Active than others, and that it may be deſervedly Rank't amongſt the Active Principles, and therefore falls under the Expanſive; whereas Salt remains Diſguiſed in the Earth, after the other Principles are Extracted, and conſequently belongs to the Contractive.

The Real Principles of Chymiſtry are the Expanſive and Contractive Forces in Various Mixtures and Combinations of them.

Lemery, Pag. 10.
Dr. Freind, Pag. 7.

Lemery, Pag. 5. and Pag. 4.

§. 6. As to Spirits, they are Subtile, Piercing, and Light Subſtances, and more in Motion than any other of the Principles, and are of Three Sorts, the Spirit of Animals, the Burning Spirit of Vegetables, and the Acid Spirit; the Firſt, as of

The Different Sorts of Spirits in Chymiſtry Accounted for by theſe Forces.

Lemery, Pag. 3. 9, 10.

Hartſhorn, is ſaid to be nothing but a Volatile Salt Diſſolved by Phlegm, the Second, as Alcohol, or Spirit of Wine, Spirit of Juniper and Roſemary, an Exalted Oil; and the Third, as the Spirit of Vinegar, Tartar, and Vitriol, an Acid Eſſential Salt put into Fuſion, and made Fluid by Fire.

The Spirit of Animals therefore Proceeds from a ſmall Expanſive Force into a ſmall Contractive one, as Phlegm has but a ſmall Degree of Expanſion, being only Fluid and not Fiery, as rather Raiſed by Fire, than Formed by it; and the Volatile Salt has but a ſmall Degree of Contraction, being made in ſome Reſpect Expanſive by the Expanſive Force in the Circulations of the Humours in the Animal, from which it is Extracted.

The Burning Spirit of Vegetables is therefore Compounded of a Greater Degree of the Expanſive, than the Former Spirit, and of almoſt an Equal one of the Contractive, by the Firſt of which it becomes Inflammable, and by the Laſt Oleous and Clammy, and the Parts more ſtrongly Cohere and are more Firmly united to one another, than in Spirit of Animals; and this is Evident from the Different Conſtitution of Animals and Vegetables, the Former being ſupported by the Proper and Weaker Expanſion of the Circulation of it's own Humours, which are of a leſs Contractive Nature, and the Latter by the vaſt Expanſive Force of the Sun, Acting upon a Groſſer, more Contractive, and Earthy Matter.

The Acid Spirit therefore is Formed from a Great Expanſive Force of Fire into a Great Contractive of Tartar or Vitriol, and is the Reverſe of thoſe Forces, which Enter into the Compoſition of the Spirit of Animals, by the Former of which it becomes a Spirit and Fluid, and by the Latter Acid and Fixt, as to it's Salts, and it is not Inflammable, becauſe the Expanſive is ſufficient to raiſe the Contractive into a Spirit, but not to diſpoſe it to a farther Activity.

From all which it is Apparent, that the Expanſive Force of the Fire has a Great Influence in Forming and Compounding theſe Spirits, and that they are not properly in Bodies themſelves, but as ſuch Bodies contain thoſe Principles and Diſpoſitions of Force, which render them capable of being Raiſed and Animated into Spirits by the Application of the Expanſive of Fire.

Concerning the Spirit of Saturn *and* Venus. Lemery, Chap. 5, 6. Part 1.

§. 7. From hence it is, that Spirits may be Drawn from Lead and Copper, becauſe their Natures are more Expanſive than thoſe of other Metals, as is Evident from the eaſy Fuſion, the Pliantneſs and Softneſs of the Firſt, by which it Approaches towards a Fluid, and from the Quick and Ready Diſſolution of the Parts of the Latter, even by Warm Water only, and it's Changeing into Ruſt and Verdegreeſe, by a Drop of Cold; From this Innate Expanſive Force it is, that they abound with Sulphurs, but to Exalt theſe Metals into a Spirit, Three Things are Required, all which Contribute to the raiſing their Innate Expanſive; Firſt, that Lead ſhould be Calcin'd into a Ceruſſe, or Copper Reduc'd to a Ruſt or a Verdegreeſe; Second, that this Ceruſſe or Verdegreeſe ſhould be mixt with a Fluid, as Vinegar, by which it Incorporates into a Salt or a Chryſtal; And Third, that it ſhould be Excited into the Higheſt Expanſive, of which it is Capable, by Fire and Diſtillation.

Concerning Spirit of Salt and Nitre. Lemery, Chap. 15, 16, Part 1.

§. 8. Spirit of Salt is made by all the Ways, which can Promote and Advance the Innate Expanſive Force, which belongs to it; It has a Great Degree of the Contractive, by it's Parts being ſo cloſely United, that the utmoſt Force of Fire is not ſufficient to diſengage them, unleſs Potter's Earth is mixt with it, or ſome other the like Subſtance; it is yet not ſo Contractive as Metals, becauſe it is Endued with a Quick and Pungent Taſt, which can only Proceed from it's Expanſive, whereas Metals in General have little or none belonging to them, and it's Parts are not ſo Solid nor ſo Heavy; it is alſo formed from a Fluid, as Sea-Water or Urine, *&c.* and conſequently is leſs Contractive and more Expanſive in it's Nature than Metals are.

The Firſt Step, taken to Raiſe it's Natural Expanſive Force into an Artificial Spirit, is, to Dry it in the Beams of the Sun, or over the Fire; Second, to Pound and Grind it to a ſmall Powder; Third, to mix Potter's Earth with it, which has an Expanſive by it's having a Deterſive or Corroſive Force; Fourth, to Temper it with Water, which, by it's being capable of Diſſolving it, has likewiſe an Expanſive Force; Fifth, to Dry this Compoſition in the Sun; And Laſtly, to Diſtill it in a Reverberatory Furnace, Firſt, by a Gentle Fire to ſeparate the Phlegm from it, and then, by Increaſing it to the utmoſt Degree, when the Spirits will come out in White Clouds, and continuing it in this Condition for 12 or 15 Hours; From all which Procedure it is Manifeſt, that every Gradation Tends to the Exalting the Expanſive Force of the Salt, till it is Formed and Excited into a Spirit, which yet, after all theſe Operations, retains a Contractive Force, which is Manifeſt from it's Acidity.

Spirit of Nitre is Drawn much the ſame Way, namely, by Reducing the Salt to a Powder, then mixing it with Potter's Earth, and afterwards Diſtilling it in a Large Retort, and in a Reverberatory Furnace, by a ſmall Fire till the Phlegm is ſeparated, and from thence Increaſing the Fire by little and little to the Second Degree, when the Spirits will come forth in White Clouds, and fill the whole Receiver; and from ſtill Increaſing the Fire to the Laſt Degree, the Vapours will come Red, and the Operation will end in about 14 Hours.

The Difference therefore betwixt theſe Two Spirits can only Proceed from the Difference of the Expanſive Forces of the Salts, from which they are Drawn, and from that of Nitre being Greater, and having a leſs Contractive Force than that of Common Salt.

That Nitre has a Greater Expanſive Force than Common Salt is from hence Evident, becauſe it is Confeſs'd to be more Volatile; it is made from a Fluid, and by the Airs Acting upon that Fluid, both which have an Expanſive Force, and by the Contractive Force of the Cold and Solid Stones, to which it Adheres, as in Cellars and in old Ruined Buildings; whereas Common Salt is Formed by the Evaporation of the Fluid from the Expanſive Force of the Sun's Rays, and leaving a Matter behind, which cannot be Evaporated by it, and which therefore cannot be Separated by the utmoſt Force of Fire; Nitre is alſo found in the Hotteſt Countries, as in *Ægypt*, where the Expanſive Force of the Sun is the ſtrongeſt.

From whence a Solution follows of the foregoing Experiment, that, with the utmoſt Force of Fire, the Spirituous Vapours of Common Salt will be only White, whereas thoſe of Nitre will be Red; which can only Proceed from the Greater Natural Expanſive Force of the one than of the other; for the Senſation of Orange or Red is Produced in us by a Greater Action upon our Organs, and White with a Leſſer, or by an Æquilibrium of the Expanſive and Contractive Blended together.

Why the Spirituous Vapours of Common Salt are White, and thoſe of Nitre Red.

From hence alſo it follows, that what Spirit of Nitre Diſſolves, the Spirit of Salt will Precipitate, becauſe the whole Moment of Spirit of Nitre has an Expanſive Force, in Reſpect of the whole Moment of the Spirit of Common Salt, which has a Contractive, and therefore the Latter, having a Greater Contractive than the Former an Expanſive, what this Diſſipates and Diſſolves, the other Precipitates and Drives to the Center by a Contrary Action.

Why Spirit of Salt Precipitates, what the Spirit of Nitre Diſſolves.

§. 9, Spirit of Sal Armoniack is made from a Salt, which has ſtill a more Volatile and Expanſive Force than Nitre.

Concerning Spirit of Sal Armoniack. Lemery, Chap. 15. Part 1.

The Natural Sal Armoniack is found in the Hotteſt Countries, as in the Parts of *Africk*, which are the neareſt to the Torrid Zone, upon Earth, which has Imbibed the Urine of Animals, and which is Sublimed into a Volatile Salt, by the Action or Expanſive Force of the Sun; Artificial Sal Armoniack is made at *Venice* with Five Parts of Urine, one of Sea Salt, and half a Part of Chimney Soot Boiled together, and Sublimed into a Volatile Salt, in which the Sea Salt cloſely Unites with the Volatile; the Reaſon of which is, becauſe the Contractive Force of the Sea Salt Acting towards a Center, whilſt the Expanſive of the Volatile Acts from one, they Cling and Faſten to each other, and are thereby ſtrongly Cemented together.

In order to Exalt this Salt into a Spirit, it is mixt with Quick-lime, after they have been both Powder'd apart; Water is then Poured upon it; and the Reſt is Performed by Diſtillation, and Increaſing the Fire to the Second Degree only, by Reaſon of it's Exceeding Volatility; all which Methods contribute to the Raiſing and Exciting the Expanſive Force into a Spirituous Subſtance.

Aqua Regalis is a Solution of Sal Armoniack in Spirit of Nitre; or it may be made with Equal Portions of Salt-Petre and Sal Gemme, with thrice as much Potter's Earth, Powder'd and Diſtill'd in the ſame Manner, as Spirit of Nitre; or it may be made with Common Sea Salt.

What Aqua Regalis is, which Diſſolves Gold.

And from hence is Manifeſt, the Reaſon of the following Phænomenons;

1ſt. Why Spirit of Nitre, or Aqua Fortis, which is only an Addition of the Spirit of Vitriol to it by a joint Diſtillation of both, will Diſſolve Silver and other Metals, but not Gold, and conſequently, why Spirit of Nitre will Raiſe a Precipitation into a Tranſparent Fluid.

2d. Why Aqua Regalis will Diſſolve Gold, but not Silver, and Spirit of Salt Diſſolve Leaf of Gold, which Aqua Fortis is not able to do.

3d. Why Spirit of Sal Armoniack, or Oil of Tartar *per Deliquium*, will Precipitate Gold Diſſolved by Aqua Regalis, and other Metals by Spirit of Nitre, as alſo, why Spirit of Salt will Precipitate what Aqua Fortis Diſſolves.

4th. Why in Spirit of Nitre Dulcify'd, or Mixt with Alcohol, or Spirit of Wine Dephlegm'd, tho' the one is an Acid, and the other a Sulphur, and not an Alkali, a Great Heat, and afterwards a ſtrong Ebullition, Ariſes, the ſame which is obſerved in the mixing of Oil of Vitriol, which is an Acid, and Oil of Turpentine, which is an Æthereal one.

5th. Why a Mixture of Equal Quantities of Spirit of Sal Armoniack and Spirit of Wine will cauſe a Coagulum.

6th. Why Oil of Vitriol, which is an Acid, mixt with the Acid Spirit of it or with Water, Produces many Times a Conſiderable Ebullition.

Why Spirit of Nitre or Aqua Fortis Diſſolves Silver and other Metals.

§. 10. As to the Firſt, that Spirit of Nitre or Aqua Fortis Diſſolves Silver, and other Metals, Proceeds from hence, namely, from a Great Contractive Force, as that of Salt being Excited into a very Great Expanſive one, as has been obſerved in the Diſtilling and Forming this Spirit; on the other Hand, Metals ſeem to be a Solid, Denſe, and Compacted Salt, into which they are capable of being Reſolved, that is, the Baſis of them is, as before in Spirit of Nitre, a Great Contractive Force, Compreſs'd into a Greater, with a Various Mixture of the Expanſive in a Small Degree, from whence ariſes the Difference of their Colours; or, which comes to the ſame, the Baſis of them is a Various Degree of the Expanſive Condens'd and Compreſs'd into a very Great Contractive; when therefore theſe Forces are Placed together, the Expanſive Force of the Spirit being Superior to the Contractive of the Metals, it Diſſipates and Diſſolves them and Reduces them to a Fluid, that is, to as Great an Expanſive as their Contractive Forces will admit of.

Why Aqua Fortis is a leſs Powerful Diſſolvent than Spirit of Nitre.

And hence it ſeems to be, that Aqua Fortis is a leſs Powerful Diſſolvent than Good Spirit of Nitre; becauſe Vitriol is leſs Volatile than Nitre is, and the Expanſive Force is thereby weaken'd, as Spirit of Vitriol is not ſo ſtrong as Spirit of Nitre; for the Moments of their Forces are Compounded of a Contractive and Expanſive, and if the Contractive of both were Equal, yet if the Expanſive of Nitre is Greater than that of Vitriol, it's Moment will be Proportionably Greater; and which is the Reaſon, that Oil of Vitriol, which is longer in Drawing, and Requires a more Intenſe Fire to do it, by which it's Expanſive is Increaſed, is Stronger and has a Greater Moment than the Spirit of it; From whence it is found Requiſite in making Salt or Vitriol of Mars, to moderate the Force of Oil of Vitriol by a Mixture of Spirit of Wine, which yet is Performed by Spirit of Vitriol without any ſuch Mixture.

Why Spirit of Nitre will Raiſe a Precipitation into a Tranſparent Fluid.

And for the ſame Reaſon Spirit of Nitre will raiſe a Precipitation, which has a Contractive Force, into a Tranſparent Fluid, in which the Expanſive is Superior to the Contractive, and which is the Occaſion of that Quick and Ready Tranſmiſſion of the Rays of Light thro' it, which have likewiſe an Expanſive one.

Why Spirit of Aqua Regalis Diſſolves Gold, when Spirit of Nitre cannot.

§. 11. On the Contrary, Spirit of Nitre will not Diſſolve Gold, which is a Metal of a Greater Contractive, as well as a Greater Expanſive than the Reſt, the Firſt is Evident by it's Weight and it's Compactneſs, and the Laſt, by it's Colour and it's Softneſs and Ductility; there muſt therefore be an Addition to the Moment of the Former Diſſolvent, by Diminiſhing the Expanſive, as little as can be, and Increaſing the Contractive, ſo as the Expanſive may Act with a Greater Weight and not a Leſs Energy, which is Performed by a Solution of Sal Armoniack in it, which, tho' Exceeding Volatile, is yet below the Expanſive Force of Spirit of Nitre, and by the Contractive Force of Salt, a Weight is added to the Contractive of it, or elſe by Diſtilling Sal Gemme or Common Salt together with Nitre and Potter's Earth, which will have the ſame Effect, ſince there will be the Contractive Force of Salt, as before, and the Volatility of it's Spirit by Diſtillation will be a little Inferior to that of the Spirit of Nitre; For in all theſe Caſes, the Contractive Force is in ſome Meaſure Repreſented by Weight in Bodies, and the Expanſive by the Velocity of them, the Moment of which is Greater, as the Velocity and the Weight is Greater.

AND therefore Aqua Regalis will not Diſſolve Silver, becauſe the Contractive Force being Greater and the Expanſive Leſs, than in Spirit of Nitre or Aqua Fortis, it's Action is too Heavy and Dull, that is, is not Quick and Expanſive enough to cauſe ſuch a Diſſolution.

THUS a Great Weight of Lead may be Moved by an Equal Weight of Lead, with a certain Degree of Velocity or the Expanſive Force annext to it, which the Greateſt Percuſſion of the Rays of the Sun, of Fire, of a Wand, or any other Expanſive Force, where the Contractive is Small, ſhall not be able to Stir, and this ſeems to be the Caſe of Aqua Regalis Diſſolving Gold, and the Spirit of Nitre not doing it.

ON the Contrary, a Feather, or any other Light, or Expanſive Subſtance, is more eaſily Moved with a Breath or by an Expanſive Force, which has the leaſt Degree of the Contractive, than by the Motion and Action of Lead, which has a Greater Contractive and Leſs Expanſive, and which inſtead of Moving the Feather, Oppreſſes it's Action by it's Superior Force of the Contractive, and this ſeems to be the Caſe of Spirit of Nitre or Aqua Fortis Diſſolving Silver, and Aqua Regalis not doing it.

FROM hence it is likewiſe Manifeſt, why Spirit of Salt Diſſolves Leaf of Gold, which Aqua Fortis or Spirit of Nitre is not able to do, becauſe Gold, as before, Requires a Greater Contractive and a Leſs Expanſive to Diſſolve it, and Spirit of Salt has a Greater Contractive Force than Spirit of Nitre, according to what has been already ſaid in Reſpect of each of them; and why Spirit of Salt can Diſſolve Leaf of Gold, when it cannot a Maſs of it, and which only Aqua Regalis can do, the Reaſon ſeems to be, becauſe there is not ſo Great an Expanſive Force required to Diſſolve the one as the other, as Spirit of Salt has a Leſs Degree of the Expanſive, than Spirit of Nitre mixt with Sal Armoniack has.

Why Spirit of Salt Diſſolves Leaf of Gold, which Spirit of Nitre cannot.

LASTLY, From the ſame Principles, Vinegar Diſſolves Lead, which Aqua Fortis cannot, and Aqua Fortis Quick-ſilver, which Vinegar cannot, becauſe, Lead requires a Leſſer Contractive and a Leſs Expanſive to Move it, which is found in Vinegar, and Quick-ſilver a Greater Expanſive and a Greater Contractive, which is found in Aqua Fortis; the Firſt Metal having a Leſs Expanſive from it's Softneſs, Ductility, and Dull Colour, and a Leſs Contractive from it's Weight; and the Laſt a Greater Expanſive from it's Volatility and Bright Colour, and a Greater Contractive from it's Weight.

Why Vinegar Diſſolves Lead, which Aqua Fortis cannot. Lemery's Principles of Chymiſtry, Pag. 25. Edit. 3.

§. 12. SPIRIT of Sal Armoniack Precipitates Gold, which Aqua Regalis, or Silver, *&c.* which Spirit of Nitre or Aqua Fortis Diſſolves; becauſe Spirit of Sal Armoniack has a Greater Expanſive Force and a Leſs Contractive than Aqua Regalis or Spirit of Nitre, and therefore Weakens and Enervates the Contractive of the Diſſolvents, which was neceſſary to the making an Impreſſion upon thoſe Metals, by which their Moments become too Light and Spirituous to ſupport their Diſſolutions; On the Contrary, Oil of Tartar per Deliquium, which is a Salt, that by Calcination and Fire firſt, and by the Air afterwards acquires a Dull and Languid Degree of the Expanſive, and retains a Conſiderable one of the Contractive, will cauſe the ſame Precipitations; becauſe here the Contractive is too Powerful for, and Oppreſſes, the Expanſive of the Diſſolvents, and by a contrary Force Drives to the Bottom, what the Former had Raiſed.

Why Spirit of Sal Armoniack Precipitates Gold, which Aqua Regalis, or Silver, &c. *which Spirit of Nitre or Aqua Fortis Diſſolves.*

THUS likewiſe Spirit of Salt, which obtains an Expanſive Force from it's Spirit, and a Good Degree of the Contractive from the fixtneſs of it's Salt, Precipitates what Spirit of Nitre Diſſolves, by Acting contrary to, and Loading the Expanſive Force of it, from whence the Metal ſubſides; for Spirit of Salt has a Leſs Degree of the Expanſive and a Greater of the Contractive than Spirit of Nitre, as is Evident before from the Formation and Compoſition of them.

§. 13. IN Spirit of Nitre Dulcify'd, that is, where Spirit of Nitre is mixt with Alcohol, or Spirit of Wine Dephlegm'd, tho' the one is Termed an Acid, and the other is not, what is called an Alkali, but is eſteemed a Sulphur, there is a Great Efferveſcence, and afterwards a Strong Ebullition ariſes.

Concerning Spirit of Wine and Alcohol, and why Spirit of Nitre mixt with Spirit of Wine

Dephlegmed, or Alcohol, Cauſes an Ebullition. Lemery, Chap. 19. Part 2.

But before we Endeavour at a Solution of this Phænomenon, it will be neceſſary to give an Account, by what Methods and from what Principles the Spirit of Wine is made, as we have already done in Spirit of Nitre; Wine is the Muſte or Juice of Grapes, which by Fermentation is Raiſed into a Spirituous Subſtance, and is more or leſs Groſs, according as it abounds more or leſs with Tartar, which conſiſts of Earthy and Saline Parts, which are Drawn from the Earth into the Grape; Muſte is Sweet and not in the leaſt Intoxicating, and Changes into Wine by the Expanſive Force of the Air, which Ferments it, ſo that the Contractive Force, which is that of Tartar and Salt, is Firſt Rais'd and Excited by Vegetation, by which it acquires a Degree of the Expanſive, and is the Cauſe of the Agreeable Taſt in Grapes Compounded of the Expanſive and Contractive, by the Firſt of which they are Sweet, and by the Laſt have a little Acidity and Sharpneſs; upon the Bruiſing and Preſſing of the Grapes, the Expanſive is ſomething Increas'd, and the Contractive ſtill Diminiſh'd; and laſtly, by Fermentation, in which the Air Performs the Office of Fire in the Diſtillations of more Contractive Subſtances, the Expanſive is ſtill raiſed to an Higher Degree, by which means it becomes Intoxicating and Spirituous, and the Contractive is farther Diminiſh'd by a Separation of the Tartar from it to the Sides of the Veſſel, or Precipitating to the Lees; ſo that, when it is Wine, we may conſider it, as Conſiſting of a Great Degree of the Expanſive, and of a very Small one of the Contractive.

This Expanſive Force is ſtill farther raiſed by Diſtillation and a Gentle Fire into Brandy or Aqua Vitæ, when that which is Drawn off into the Receiver becomes Inflammable, and Greater Plenty of Brandy is Extracted from Wines, which are Lighter and more Spirituous, that is, which have a Greater Degree of the Expanſive, and a Leſs of the Contractive, than from ſtronger Wines, which have a Greater Contractive Force in them; Spirit of Wine is the Diſtillation of Brandy in a Vaporous Bath, which ſhews the Exceeding Expanſiveneſs of it; and when it is Dephlegm'd, that is, cleared of all it's Contractive Force, as much as Poſſible, it becomes, what is, by the Chymiſts, called Alcohol; which therefore is a Liquor raiſed from a Tartar and Salt in the Earth, which has a Moderate Contractive Force to an Expanſive in Alcohol, which has little or none at all, for take a Spoonful of it, and throw it in the Air, and it will be immediately Diſſipated, without Falling, or Contracting into Drops, as all other Liquors do.

This therefore being the Nature of Spirit of Wine Dephlegm'd, or of Alcohol, namely, that it obtains the utmoſt Degree of the Expanſive, and the moſt Minute, which can be Imagined of the Contractive, it will not have any Moment to Diſſolve Metals, but Spirit of Nitre, which has a Great Degree of the Expanſive, and a Good Degree of the Contractive, will do it, and in the Operation cauſes an Efferveſcence.

On the Contrary, the ſame Alcohol, or Dephlegm'd Spirit of Wine, which has a Great Expanſive Force, and a Small Contractive, will have that Effect upon Spirit of Nitre, which has a Leſs Expanſive Force, and a Greater Contractive, by cauſing an Efferveſcence and Ebullition, and by Diſſolving it's Contractive Force, and Dulcifying it's Acidity, which Spirit of Nitre, which has a Greater Expanſive Force, and a Leſs Contractive than Metals, has upon them, by Producing alſo an Efferveſcence and Diſſolving their Contractive.

From whence Efferveſcence and Ebullition is cauſed in General, and what are Acid and Alkali.

From whence it follows, that Efferveſcence and Ebullition ariſes from the Conteſt, which there is betwixt Two Contrary Forces, the Expanſive and Contractive; and it is neceſſary it ſhould be ſo; for in any Fluid, where the Forces are the ſame, there is a perfect Quieſcence, as in Water, in Spirit of Nitre, Oil of Vitriol, Spirit of Sal Armoniack, *&c.* which mixt with others would occaſion the utmoſt Tumult and Diſorder; which can therefore only Proceed from the Difference and Diſparity of ſuch Forces, which Contend with each other, till the one or the other Prevails, which is the Reaſon of their Ebullition, and, whilſt ſuch a Conteſt laſts, the Medium about them is ſuitably Affected, is raiſed into a Ferment, and ſtrikes a Senſation of Heat upon the Organs, which are apply'd to it.

And Bodies do not cauſe this Efferveſcence and Ebullition, as they are Acid or Alkali, but as they have Expanſive and Contractive Forces, Acting Contrary and in Oppoſition to each other; Thus an Acid Spirit has a Great Expanſive Force, and a

Small Contractive, as Spirit of Nitre, Oil of Vitriol, *&c.* in Reſpect of Alkalis or Salts Calcined, which have a Great Contractive from the Salt, and a Small Expanſive from the Fire; And from hence it is, that what is an Acid in one Caſe, may be an Alkali in another, for what has an Expanſive Force in Reſpect of Metals, may have a Contractive in Reſpect of Liquors, which are more Spirituous than it; Thus Spirit of Nitre is an Acid, or has an Expanſive Force in Reſpect of Metals, which have a Contractive or Alkalic, but in Reſpect of Alcohol, Spirit of Nitre has a Contractive, and Alcohol an Expanſive; Spirit of Salt, in Reſpect of Leaf Gold, is Expanſive, in Reſpect of Aqua Fortis, is Contractive.

Lemery, Chap. 27. Part 2. Edit. 3.

For the ſame Reaſon it is, that Oil of Vitriol, which has a Great Contractive Force, as is Evident from it's Acidity, and from the Nature of Vitriol, which is a ſtrong Compacted Salt, and Oil of Turpentine, which is a Vegetable and Æthereal Oil, and has therefore a Great Degree of the Expanſive, both from the Nature of it, which is a Searching and Penetrating Liquor, that Diſtills in hot Countries, as in *Italy*, *Spain*, *Cyprus*, the Iſle of *Chios*, *Provence* and *Dauphine*, from ſeveral Kinds of Trees by the Inciſion of them, and from the Diſtillation and Increaſe of the Fire to Produce it; the Heat of the Sun, the Vegetation, and Fire in Diſtilling it, all, Contributing to Raiſe and Exalt the Expanſive Force of it; For the ſame Reaſon it is, that theſe Two Oils, by the Oppoſition of their Contractive and Expanſive Forces, occaſion an Efferveſcence and Ebullition; And the ſtrong Ebullition, which ariſes from Pouring Aqua Fortis or Oil of Vitriol upon an Alkali Salt, Proceeds from no other Cauſe, the Oil of Vitriol being the ſame or a like Force to the Alkali Salt, as the Oil of Turpentine is to the Oil of Vitriol; the Former, namely, Oil of Vitriol and Oil of Turpentine, in their ſeveral Reſpects to the Latter, that is, Alkali and Oil of Vitriol, having a Greater Expanſive Force and a Leſs Contractive, and the Latter a Greater Contractive and Leſs Expanſive.

Lemery, Chap. 18. Part 1. Pag. 419, 421.

Thus alſo Spirit of Vitriol mixt with Oil of Vitriol, or Oil of Vitriol with Water, will cauſe a conſiderable Ebullition, for Oil of Vitriol has a Greater Contractive and a Leſs Expanſive than the Spirit, it being Confeſs'd by Chymiſts, that the one is the more fixt Part of the other; Spirit of Vitriol, therefore in this Caſe, will Perform what Oil of Turpentine did in the Former, and having a Greater Expanſive and a Leſs Contractive, than the Oil, will raiſe it into an Ebullition, as Fire does Water.

On the Contrary, Oil of Vitriol, albeit it has a good Degree of the Contractive, yet having a Vaſt Expanſive Force likewiſe, tho' Inferior to that of it's Spirit, Expands it ſelf in Water, which has a Small Expanſive Force, and a Greater Contractive, and therefore Oil of Vitriol is to Water, as Spirit of Vitriol to the Oil; Juſt, as before, Oil of Vitriol was to the Alkali Salt, as Spirit of Turpentine to Oil of Vitriol.

Oil of Vitriol is a Fluid Fire or a Burning Fluid, becauſe it's Expanſive Force is exceeding Great, and it's Contractive very Conſiderable, by which there is a Weight and Moment added to the Expanſive, which makes it approach to the Nature of Fire: By the ſame way, all other Effervеſcences and Ebullitions may be Expounded, we ſhall therefore now only add ſomething concerning Fire and Flame.

Concerning Fire and Flame Producible in Chymiſtry. Sir If. Newt. Optic. Quer. 31.

§. 14. If Two Parts of a Spirit, Drawn and Compounded from Oil of Vitriol and Nitre, are Poured upon one Part of Oil of Cloves, or Caraway Seeds, or any Ponderous Oil of Vegetable or Animal Subſtances, or Oil of Turpentine thickened with a little Balſam of Sulphur, there will immediately be Produced a Burning Flame, the Reaſon of which is the ſame, as that of the foregoing Phænomenons,

The Expanſive Force of Oil of Vitriol is Loaded with too Great a Degree of the Contractive, which Force is therefore corrected by Nitre, which is more Volatile than Vitriol, and made ſtill more Expanſive by it's Diſtillation with the Oil of it.

On the Contrary, Spirit of Nitre would have too Great an Expanſive Force, by which it is capable in Conjunction with it's Contractive to Diſſolve Metals, a Middle Proportion of both theſe Forces therefore muſt be taken to Diſſolve the Oils above-mentioned.

The Oils muſt be Ponderous, and Oil of Turpentine Thicken'd with Balſam of Sulphur, that they may have a certain Degree of the Contractive to be ſurmounted by that of the Vitriol Actuated by the Expanſive, they muſt be the Oils of Vegetable or Animal Subſtances, that they may have a certain Degree of the Expanſive, by which they are diſpoſed to riſe into Flame by the Action and Force of the Compound Spirit of Nitre.

Lemery, Chap. 3. Part 1. Pag. 110.

For the ſame Reaſon it is, that Tin Powder'd, by the Extreme Force of Fire in Calcining it, acquires a Degree of the Expanſive, which becomes Inflammable by Mixing a Diſſolution of Silver, Precipitate with Salt Water, and Dry'd; the Spirit of Nitre, made leſs Expanſive by the Diſſolution, obtaining the Effect of the Compound Spirit before, and the Powder'd Tin, that of the Ponderous and Vegetable Oil.

Thus alſo Common Fire and Flame Proceeds from the Expanſive Force of Fire and Air, which has a Degree of the Contractive in Reſpect of the Former, Acting upon the Sulphureous or Expanſive Nature of the Fuel, and it's Contractive Force, by which ſuch Bodies become Solid and Heavy; Hence all Vegetables, Wood and other the like Materials Dry'd, Coals and Sulphureous Bodies, are Inflammable in Various Degrees, from their Expanſive Force, but Stone, Clay, Earth, and Metals, not ſo, by their being too Contractive; Hence likewiſe, Oils from their Expanſive Force are Inflammant, but Salts from their Contractive do not Admit of that Property.

Why a Veſſel of Boiling Water ſhall be Cool at the Bottom and Hot on the Sides.

It has been Eſteemed a Problem in Nature hard to be Solved, tho' what is Juſtified by Common Experience, why in a Veſſel full of Water, ſet over a Fire, the Water ſhould Boil, when the Bottom of the Veſſel is, in Compariſon, Cool, and yet the Sides of it ſhall be Extremely Hot; The Reaſon of which is, becauſe the Expanſive Force of the Fire, not being able to ſubdue the Contractive of the Metal, Paſſes to the Contractive of the Water, betwixt which and the Fire the Conteſt therefore lies, and is raiſed into an Ebullition by it; but as the Expanſive Force Aſcends by the Sides of the Veſſel, the Conteſt will be betwixt the Fire and the Contractive Force of the Metal, from whence the Intenſe Heat of it is cauſed; when the Veſſel is taken off the Fire, the Bottom of it grows Hot by the Expanſive Force, which now Prevails in the Water, Returning upon the Contractive of the Metal, betwixt which Forces now the Conteſt lies.

Air, which in Reſpect of Fire, has a Contractive Force, and which being the Greateſt in Cold and Froſty Weather, makes Fire burn more Fiercely, in Reſpect of Water, has an Expanſive, by which it Ferments and Actuates it, and in certain Caſes Raiſes it into Vegetation.

Concerning Air or Æther, and the Cauſe of it's Elaſticity and it's Effects in Vegetation.

§. 15. Air or Æther is a Medium known to be Elaſtick, but whence that Elaſticity is Produced, has been little Explained, which Probably Ariſes from it's Expanſive Force, Mixt in a due Proportion with it's Contractive; the Firſt being chiefly Impreſs'd upon it by the Sun's Expanſive Force, and the Moon's Contractive, which Acts in Conjunction with it, and in Oppoſition to the Earth, as has been ſhewn in Tides; and the Laſt from the Earth's Contractive, which Acts contrary to the other; by which means the Air is a Medium Stretch'd and Pulled betwixt Two Oppoſite and Contranitent Forces, from whence it becomes Elaſtick, like a String or Wire under Tenſion from Forces Acting a Different way at the Two Extremities of it.

Whence the Colours of Natural Bodies, and how Drops of Water becomes Spherical.

This Elaſtickneſs of Air or Æther is the Cauſe of it's being ſuſceptible of the leaſt Percuſſions from the Expanſive Force of Bodies, by which we ſee and are made ſenſible of the Various Colours of them; From the ſame Elaſtick and Expanſive Force, Exerting it ſelf Equably on Water dropt in Air, and from the Contractive Force of the Water, by which it's Parts are Equably Drawn to each other, it is, that the Figures of theſe Drops are Spherical.

Whence Plants and Trees have their Cylindrical Form, and Circular or Oval Foliage.

Plants and Trees, likewiſe in General, have a Cylindrical Form upon the like Account, the proper Expanſive Force in Vegetation, diſplaying it ſelf Round to a certain Degree, is bounded by the Contrary Expanſive or Contractive of the Air, which Acting Equably on all Hands, keeps the Vegetating Force within the Circular Limits it Preſcribes, excepting where it Shoots upwards in the Stock, or downwards from the Root by a Superiority of Force, by which means the Cylinder is Framed; when the main Expanſive Force is ſpent, and the Trunk can riſe no Higher, it then Shoots out into Lateral Directions and Branches, which for the Reaſon above are ſtill Cylindrical, but when theſe are Formed, and the Expanſive is Enervated and Weaken'd, it ſinks into Flat Leaves, which yet are generally Circular, or Approaching

ing to that Figure by the ſame proper Expanſive Force of Vegetation, and the contrary Expanſive of the Air Acting Equably upon it.

See alſo Chap. 5. §. 20. Book 1.

The laſt Effort in Vegetation is the Expanſive Force ſtriking out into ſharp Points, which is the Cauſe, that moſt Leaves are ſurrounded with little Indentations, and which Proceed from the final Exertion of the Expanſive, in the Plant or the Tree, and the Renitency of the Air's Contractive, or Contrary Expanſive; I have mentioned thus much of Air here, as Eſteeming it amongſt the Spirits, of which I am now Treating, tho' the moſt Moderate and Gentle, and the beſt Adapted to all the uſes of Animal Life and Vegetation, of any other Spirit whatſoever.

Why Equal Quantities of Spirit of Sal Armoniack and Spirit of Wine will Cauſe a Coagulum.

§. 16. **Equal** Quantities of Spirit of Sal Armoniack and Spirit of Wine will cauſe a Coagulum, becauſe the Moments of their Forces are Equally Balanced and Contrary to each other; From whence they will Cling together, and mutually Cohere, and Produce a Poſitive or Active Reſt, or Union of their Forces; Spirit of Wine mixt with Spirit of Nitre Cauſes an Ebullition and Diſſolves it's Acidity, as has been before ſhewn, that is, the Expanſive Force of the Spirit of Wine is Superior to the Contractive of Spirit of Nitre; but Spirit of Sal Armoniack is more Volatile and Expanſive than Spirit of Nitre, and therefore comes nearer to the Expanſive Force of Spirit of Wine, and their Forces are Contrary, becauſe Spirit of Wine is an Oleous one, that is, almoſt entirely Conſiſts of an Expanſive, but Spirit of Sal Armoniack has from it's Salts a Contractive; And for the ſame Reaſon, Oil mixt with a Saline Liquor in a Mortar will form an Unguent called Nutritum, which can Proceed from nothing but the Expanſive of the Oil, which is Inflammable, Acting contrary to the Contractive of the Salt, which Decrepitates in Fire, with nearly Equal Forces, by which they are United and Cemented together in a cloſer Coheſion; And this may give an Account of the Conſiſtency of all Bodies, which ſeem to be little more than ſtronger Coagulums, ariſing from the Mutual and perhaps nearly Equal Actions of the Expanſive and Contractive, whoſe Forces are yet much Greater than thoſe here alledged of Wine and Sal Armoniack.

Lemery, Chap. 17. Pag. 399.

Lemery, Chap. 18. Part 1. Pag. 421.

From hence alſo it is Evident, why Spirit of Vitriol, remaining ſome Time upon Iron, reincorporates into Vitriol, and Spirit of Nitre poured upon Salt of Tartar returns into Nitre; Green Engliſh Vitriol, out of which the Spirit is formed, is ſaid to partake of Iron, and Mars or Iron may be Reduced to a Green Vitriol, by Diſſolving it in the Spirit, Filtrating and Evaporating the Solution to a Skin, and ſetting it to Cool; As therefore the Contractive Force of Iron may be Exalted into a Green Tranſparent Chryſtal by the Expanſive Force of the Spirit, when made to Evaporate and Set to Cool, ſo it is no wonder, that the ſame Expanſive Force of the Spirit, remaining for ſome Time upon the Iron, by which means it is Evaporated and Weakened, ſhould be changed into Vitriol by the Contractive of the Iron, and ſo likewiſe, that Spirit of Nitre poured upon Salt of Tartar ſhould by the Contractive Force of the Latter, and the Evaporation of the Expanſive of the Former, Coagulate into Nitre; ſince theſe, as thoſe others before of Spirit of Wine and Spirit of Sal Armoniack, ſeem to Act with nearly Equal and Contrary Forces.

Concerning the Depart, *by the Diſſolvent's quitting one Metal, which Precipitates, and betaking it ſelf to another, with the Reaſon of it.*

§. 17. **There** is one Phænomenon more, which I ſhall take Notice of in Reſpect of the Spirits in Chymiſtry, which is that of the *Depart*, which is the Parting of Metals, by the Diſſolvent's quitting one Metal, which Precipitates to the Bottom, and betaking it ſelf to another. Thus when Aqua Fortis has Diſſolved Silver, and Copper is put into the Diſſolution, the Silver Precipitates, and the Copper is Diſſolved; Iron Precipitates Copper, Lapis Calaminaris Iron, and the Liquor of fixt Nitre Precipitates Lapis Calaminaris.

Lemery, Chap. 2. Pag. 92, 93. Part 1.

The Reaſon of which ſeems to be this, that Silver requires all the Expanſive and Contractive Force of Aqua Fortis or Spirit of Nitre to Diſſolve it; Copper, by an Addition of it's Contractive Force, Acts againſt the Expanſive of the Spirit of Nitre, by which it is ſo far weakened as to be no longer able to ſupport the Silver, which therefore ſubſides, but the Expanſive thus weakened and retaining ſomething of the Silver, which it has Diſſolved, is ſufficient to ſubdue the Leſs Contractive Force of the Copper; and thus we find even Diſtill'd Vinegar, which has a much leſs Expanſive and Contractive Force than Spirit of Nitre, able to Diſſolve Verdegreeſe, which is only a Copper opened and reduced to a Ruſt by the Fermenting Spirits of Tartar; what therefore Diſtilled Vinegar can Perform upon Copper opened, it is reaſonable to think, that Spirit of Nitre weakened in its Expanſive Force, but increaſed in it's Moment of the Contractive by the Silver, which it ſupports, may Perform in Reſpect of Copper, which is crude and unopened, and not ſo fully prepared for a Solution.

For the ſame Reaſon, Iron, whoſe Specifick Gravity or Contractive Force is to Copper, as ſomething more than 7 to 9, as Copper is to Silver as about 9 to 11, will Precipitate Copper, whilſt the Spirit of Nitre will ſtill obtain a ſufficient Expanſive Force to Diſſolve the Former; and the ſame may be ſaid of Lapis Calaminaris, and the Liquor of fixt Nitre, which Decreaſe in their Contractive Forces from the foregoing, as the Expanſive Force of the Spirit of Nitre or Aqua Fortis is Impaired by the Solutions.

Concerning the Phlegm, and the Oil of Chymiſts.

§. 18. Having therefore gone thro' what we intended in Relation to the Spirits in Chymiſtry, we ſhall now Proceed to the next Active Principles in it, which are the Phlegm and the Oil, and which are only ſtill Leſſer Degrees of the Expanſive Formed and Raiſed by the Fire, and are more or leſs Expanſive, according to the Greater or Leſs Expanſive Nature of the Subſtances, from which they are Extracted; Phlegm, as being little more than a Fluid, has but a Small Degree of the Expanſive, and Oil, where it is Inflammable, has a Greater; and where it is not, has a Greater Degree of the Contractive, as in Oil of Vitriol, which is not Raiſed but by a very Violent Force of the Expanſive of the Fire, concerning which we have already ſpoken.

The Principal Difference betwixt Spirit, Phlegm, and Oil.

The Principal Difference betwixt the Spirits, Phlegm, and Oil in Chymiſtry, Abſtracting from the Natures, from which they are Drawn, which would diverſify them to Infinity, ſeems to be in General this, that Spirit acquires the Greateſt Degree of the Expanſive by the Operation of the Fire, and which it is capable of Exerting upon other Bodies, to which it is Applied; Oil has a Leſs Degree of the Expanſive, and which is always joined with a Greater Degree of the Contractive, from whence it becomes a Thicker and more Glutinous Subſtance than the Spirit, and therefore is not ſo capable of Exerting it's Action upon other Bodies, but yet is Prepared, by this Mixture of the Expanſive with the Contractive, to obey the Expanſive Force of Fire, and to riſe into a Flame.

Phlegm acquires but a Small Portion of the Expanſive, and has but little of the Contractive, being nothing elſe than the Moiſture of Bodies, which ſits looſe in them without partaking of the Real Qualities of them, and therefore eaſily comes forth in Vapours, and differs not much from Common Water, Excepting that it receives ſome Small Impreſſions from the Active Principles, and has thereby a more Deterſive, that is, Expanſive Vertue than Common Water; which is alſo the Caſe of Rain and Dew, being Impregnated with, and made more Expanſive by, the Spirit of the Air; we ſhall therefore Say nothing farther of the Phlegm propoſed to us by Chymiſts, but Proceed more particularly to Specify their Oils.

Lemery, Pag. 163.

The ſeveral Oils of the Chymiſts Conſidered.

Lemery, Pag. 4. 7. 11. 19. Edit. 3.

§. 19. Oil or Sulphur is ſaid to be a Sweet, Subtile, and Unctuous Subſtance, which riſes after the Spirit, and is Inflammable; which Character exactly Agrees with the Forces we before Aſſigned it, that it has a Leſs Expanſive and a Greater Contractive, than that which belongs to Spirit, tho', like Spirits, it muſt be Different, according as the Nature, from which it is Extracted, is more or leſs Expanſive or Contractive.

Why Oil of Roſemary or Lavender will Swim upon Water, whilſt Oil of Box, Guaiacum, or Cloves, Sinks to the Bottom.

Thus Oil of Roſemary or Lavender will Swim upon Water, whilſt Oil of Box, Guaiacum, or Cloves, Precipitates to the Bottom; which is not a Proof, as Chymiſts Imagine, that theſe Oils are drawn Impure, and that the Former are mixt with Spirits, and that the Latter are filled with Salts; but that Roſemary and Lavender have a more Expanſive and Volatile Nature, which is Evident from the Briskneſs, and Liveline ſs of their Smell, and that Box, Guaiacum, and Cloves, have a more Contractive, which likewiſe may be eaſily acknowledged from their Fainter and Duller ones; and therefore the Oils of the one will be Lighter and more Expanſive, and thoſe of the other more Contractive and Heavier.

Why ſome Oils are Drawn by Inciſion, others

Hence it is alſo, that ſome Oils may be drawn by Inciſion only into the Root or Trunk of Trees, as that of Turpentine; others by Beating and Preſſing the Fruits and Seeds, which are Contained in Them, as thoſe of Olives, Almonds, and Nuts;

whilſt others are not Extracted without the Greateſt Force of Fire, as Oil of Vitriol; the Firſt ſeems to have the Greateſt Degree of the Expanſive, the Second a ſtill Leſs, and the Laſt, tho' it has a Great Degree of the Expanſive, yet is joined with a Great Degree of the Contractive.

by Expreſſion, and a Third by Fire.

That Oil is Inflammable not from Salts, but from the Expanſive Force, which thoſe Salts acquire.

§. 20. It is Affirmed by Chymiſts, that nothing but Oil can properly be ſaid to be Inflammable, and that the Oil is ſo much the more ſo, as the Salts, with which it is cloſely United, have been more or leſs Spiritualized, as if the Salts contributed to their Inflammation.

Whereas, as we Eſteem Salt to be of a Contractive Nature, and Flame to be of an Expanſive one, it will be hard to conceive, how the one ſhould be Aſſiſtant to the other; eſpecially, when it is acknowledged, that the more Volatile and Expanſive the Salts are, which are mixt with the Oil, the readier it is to be Imflamed; and on the Contrary, that fixt Salt entirely Hinders and Obſtructs Inflammation, as is Evident from Sea Salt thrown into the Fire, which ſerves not to Raiſe and Excite, but to Extinguiſh it.

It muſt therefore be ſaid, that Spirit of Wine, which is reckoned to be an Oleous one, and which muſt conſequently be the moſt Perfect Oil, which is Poſſible, is only Salt, or the Contractive Force, Exalted to the Higheſt Degree of the Expanſive; for that all Bodies have Salt, or a Contractive Force, has been ſhewn, and that this Contractive Force is raiſed into the utmoſt Expanſion in Alcohol or Spirit of Wine Dephlegm'd; any Oil therefore is nothing more than Salt Volatilized, or the Contractive Force Actuated with a Great Degree of the Expanſive; From whence it Enſues, that it is not the Mixture of Oil with Nitre or any other Volatile Salt, which is the Occaſion of Inflammability, but the Raiſing a Salt, or a Contractive Force, into a ſufficient Degree of Expanſiveneſs to be Acted upon by Fire and thrown into a Flame.

If therefore Salt Petre mixt with any Oily Subſtance makes ſuch Oil more eaſily Inflamed, whereas Nitre is not it ſelf Inflammable, it Proceeds from hence, that the Contractive of the Oily Subſtance, or the Salt of it, is more fixt than that of Nitre, and which, when mixt with it, abates that Contractive Force, and aſſiſts the Expanſive of the Oil; ſo that if it were Poſſible to draw the more Spirituous Part from ſuch Oil, the Salt or Contractive Force remaining would be leſs Inflammable than Nitre it ſelf, which is in ſome meaſure Evident from the Dull Salts or Earths, which are left after ſuch Oily Extractions are made. Or elſe this muſt be from the Contractive of the Salt, Exciting the Expanſive of Flame by Oppoſition, as Water or Air does Fire.

Oils of whatever Sort, only Spirits with a more Contractive Force belonging to them, and the Nature of them Explained. Lemery, Pag. 19, 12.

§. 21. It is ſaid, that the Oil of Vegetables is the Fat and Unctuous Part of Earth mixing and inſinuating it ſelf with Salt, and that many Things are improperly called Oils, as Oil of Tartar per Deliquium, Oil of Vitriol, and that of Antimony.

As to the Firſt, it may be more truly ſaid, that Vegetable Oil is a more Phlegmatick, that is, a more Contractive Burning Spirit of Vegetable, which has a Leſs Degree of the Expanſive than the Former, but is much of the ſame Nature; And as to the Second, that Oil of Vitriol, and ſo of the Reſt, may be as juſtly Termed an Oil, as the Spirit of it may be acknowledged to be ſuch, ſince it is a more Contractive Spirit only of the ſame Mineral; that is, we cannot but think, that as Spirits are either thoſe of Animals, Vegetables, or Minerals, and accordingly are either Volatile, Burning, or Acid, or have a Middle Expanſive and Contractive Force belonging to them, as in the Firſt Caſe, or a Greater Expanſive, with a Little Contractive, as in the Second, or a Leſs Expanſive and a Greater Contractive, as in the Third, ſo it is ſuitably in the Oils of them, tho' the Expanſive Force in their Oils is Leſs, and the Contractive Greater, than in their Spirits; and conſequently theſe Oils are ſtill Salts, or the Contractive Force, not raiſed to ſo high a Degree in Them, as in the Spirits; and there may be Volatile, Burning, and Acid Oils, as well as Spirits.

The Oils of each ſort alledged in Chymiſtry.

To Confirm what I ſay, I ſhall only Inſtance in ſome of the Oils of each Sort alledged in Chymiſtry; in Reſpect of the Oil of Minerals, I ſhall take thoſe of *Mars*, *Saturn*, *Venus*, Antimony, and Vitriol; of Vegetables, thoſe of Tartar, Cloves, Turpentine, and Cinnamon; of Animals, thoſe of Vipers and Hartſhorn; in the Firſt of which we ſhall find ſome Marks, or other, of a Greater Contractive Force, than what is Experienc'd in the Oils of Vegetables or of Animals, by their Vertue

Oil of Mars. Lemery, Pag. 174. *Oil of* Saturn. Pag. 136. *Oil of* Venus. Pag. 147. *Oil of Vitriol.* Pag. 425.

of Removing Obſtructions, which is the Caſe of the Oil of *Mars*, which Fire and Expanſive Forces cannot do; or by Cleanſing and Cicatrizing of Ulcers, and Reſiſting Putrefaction or Expanſion, which is the Caſe of Balſam or Oil of *Saturn*, and of the Liquor or Oil of *Venus*, of the Cauſtick Oil of Antimony, or that Prepared with the Acid Spirit, and Oil of Sugar, tho' it's Effect is in a leſs Degree than the Former; or by their Harſhneſs, Acidity, and Weight, and their Styptick Quality, which is the Caſe of the Oil of Vitriol, and of all the others foregoing in Different Degrees, according to the Different Nature of the Bodies, from which they are Drawn, and the Methods of Drawing them; theſe therefore may be properly enough Termed Oils, which have a more Contractive Nature, and are not Raiſed into ſo High a Degree of the Expanſive Force, as the Oils of Vegetables or of Animals, as the Spirits of Minerals are not ſo Expanſive, as thoſe of Vegetables or of Animals: The Oils of Animals and Vegetables are leſs Contractive, and more Expanſive, than thoſe of Minerals, Evident Marks and Characters of which we may obſerve from their Smells, which are Greater and Stronger than thoſe of Minerals, and which ſhews they have a Leſs Contractive and a Greater Expanſive Force, from their Vertues, that is, their being Good to Smell to in Hyſterical Vapours, which Proceed from too Great a Contractive Force or Melancholy in the Mind, and from the ſame Exceſs of the Contractive Force in the Humours and Animal Spirits of the Body, as alſo their being Good to rub Paralytick Parts with, and for Cold Pains, both which Diſtempers Proceed from too Great a Contractive Force in the Animal Syſtem; And this is the Caſe of Fœtid Oil of Tartar by Diſtillation, the Spirit alſo of which is approved in the Palſie, Aſthma, and Scurvy, is likewiſe uſed in Hyſterical Maladies, and for the Epilepſie, which are all of them Diſorders, that Ariſe from an Exceſs of the Contractive Force, and it is ſaid to work by Urine and by Sweat, which are manifeſt Tokens of the Remedy having the Nature of the Expanſive, and that the Oil is of the ſame kind of Force with the Spirit, tho' not ſo Expanſive.

Lemery, Pag. 592. Edit. 3.

Oil of Tartar, per Deliquium. Lemery, Pag. 594.

THE Oil of Tartar per Deliquium, by it's Compoſition and Formation, being only the fixt Salt of Tartar Calcined and made more Expanſive by Fire, and then Diluted by the Air, muſt be leſs Expanſive and more Contractive than the Fœtid Oil by Diſtillation; and therefore, tho' the Vertue of this Oil is Aperitive, and conſequently Expanſive, yet it is given for Obſtructions, as the Oil of *Mars* is, becauſe of the Good Degree of the Contractive, which is joined with the Small Expanſive Force of it.

FROM this Account of the Oil of Tartar per Deliquium is Confirmed, what we before mentioned concerning it, which was, that it acquired a Dull and Languid Degree of the Expanſive, from it's Calcination, and retained a Conſiderable one of the Contractive, from it's Salt.

Oil of Cloves. Lemery, Pag. 495.

THE Oil of Cloves is ſtill of a more Expanſive and a leſs Contractive Nature than that of Tartar, which is Evident from the Firſt being Odoriferous, and the Laſt Fœtid; ſo Spirit of Wine is more Expanſive than Spirit of Nitre and Vitriol, the Former of which is Agreeable both to the Taſt and Smell, the Latter very Abominable and Offenſive; It is alſo too Expanſive and too little Contractive to remove Groſſer or more Heavy Obſtructions, which Oil of Tartar can do, but is ſufficient to Diſſipate the Cold Humours in the Tooth-Ach, and is ſaid to be Good in Malignant Fevers and the Plague, which therefore perhaps originally Proceed from a Contractive Force prevailing in the Blood, as That is the Reaſon, in Intermitting ones, of the Cold Paroxyſms obſervable in them; This Oil is alſo Drawn with a ſmall Degree of Fire, which ſhews the Expanſiveneſs of it, and is Inflammable by a Compound Spirit of Nitre.

Oil of Turpentine. Lemery, Pag. 640.

OIL of Turpentine Diſtills from an Inciſion only into ſeveral ſorts of Trees, which grow in hot Countries, and is of the Conſiſtency of a Balſam, in Winter, and of an Oil in Summer, it is Diuretick, Good for the Stone, the Nephritick Cholick, the Retention of Urine, *&c.* has a Biteing Taſt, and is Inflammable by a Compound Spirit of Nitre; all which ſhew, that it has a Greater Expanſive and a Leſs Contractive than Oil of Tartar, and, if not a Leſs Expanſive, a Greater Contractive than Oil of Cloves, it being more Diſagreeable to the Taſt, and more Capable of Removing Greater Obſtructions, and more Thick, and Conſiſtent, and Ponderous.

Oil of Cinnamon. Lemery, Pag. 484.

Oil of Cinnamon is more Expanſive and leſs Contractive than Oil of Turpentine or Tartar, it is more Odoriferous, and is of no uſe in Obſtructions, only ſtrengthens the Stomach, and aſſiſts Nature in her Evacuations, which ſhews it has not ſo Great a Moment as the others; the ſame may be ſaid of the Oils of Lavender, Roſes, and Orange Flowers, of Box, Juniper, and Anis-ſeed, All which, with that of Cloves before, either Swim upon the Water or Precipitate to the Bottom, as they have a Leſs or Greater Contractive Force belonging to them.

Oil of Vipers. Lemery, Pag. 673.

Oil of Vipers is almoſt of the ſame Nature by it's Vertues with the Fœtid Oil of Tartar, it is ſaid to be Good in the Epilepſie, Palſie, and Hyſterical Caſes, and it's Smell is ſo Offenſive as ſcarcely to be Endured, and it ſo far, in ſome Meaſure, Agrees with the Contractive Force of the Oil of Tartar; but then it is more Expanſive by the Volatile Salts, which Vipers contain, none of which are to be found in Tartar, and therefore it is alſo uſed in Malignant Fevers and Agues, and the Bitings of Venemous Creatures, which Proceed from too Great a Contractive Force infuſed into the Blood, and mixing with it, and which Oil of Tartar has too Little an Expanſive Force to Diſſolve, tho' it is capable of Diſſolving a Greater, as in the Epilepſie and Palſie; becauſe it's Expanſive Force joined with the Contractive, which is Greater in Tartar than in Vipers, has a Greater and Stronger Moment than the Expanſive of Vipers joined with it's Contractive; and it is very Reaſonable to think this is ſo, ſince the Contractive Force in Animals, and eſpecially in ſuch a Fiery and Spirituous one as the Viper is, muſt be thought to be much Leſs from the continual Circulations of the Humours in it, than that of a fixt Salt agitated only by a Temporary Fire in Calcineing and Diſtillation.

Oil of Hartſhorn. Lemery, Pag. 735.

Oil of Hartſhorn, as well as the Volatile Salt and Spirit of it, is made in the ſame Manner as that of Vipers, it is more Expanſive and leſs Contractive, and therefore is not ſo Powerful and Momentous a Remedy as the other: From all which has been ſaid concerning Oils, it ſeems to be Evident, that they are of the ſame Nature with the Spirits of the Bodies, from which they are Extracted, only are more Contractive and leſs Expanſive than they.

Concerning the Salts of Chymiſts, with the Concluſion.

§. 22. The Firſt Contractive Principle in Chymiſtry, and the only one, I take to be Salt; and as Spirit Principally conſiſts of the Expanſive, and as Oil is a Duller Spirit, or Expanſive Force, ſo Earth is nothing, but a Duller Salt or Contractive, whoſe Force is Weakened and Impaired by the Expanſive of the Fire, as Common Earth is a Salt, whoſe Contractive Force is Diminiſhed by the continual Action of the Rays of the Sun; Salt in General is Defined by Chymiſts to be a Principle, which remains Diſguiſed in the Earth after the other Principles are Extracted, that it is a Fixt and Incombuſtible Subſtance, which gives Bodies their Conſiſtence, and preſerves them from Corruption; all which are Evident Tokens of a Force Acting contrary to an Expanſive one, which I all along call a Contractive.

Lemery, Pag. 4. Edit. 3.

That it cauſes a Diverſity of Taſts, according as it is Differently mixt, is not ſo Evident, but on the Contrary, that all Taſts Proceed from the Expanſive Force, and that the Taſts of Salts themſelves are Derived from their having a certain Degree of the Expanſive, tho' extremely Small, in Reſpect of their Contractive; for Metals, which have ſtill a Greater Contractive Force than Salts, have little or no Taſt at all, and if the Contractive Force of Salts is raiſed into a Higher Expanſive by Fire and Diſtillation, their Taſt is ſtill Stronger; thus alſo, Muſte has a weaker Taſt than Wine, and that, than Brandy, which are only ſeveral Degrees of Exalting Salt or Earth, into the Expanſive, by Vegetation, Fermentation, and Diſtilling with Fire.

Salts are affirmed to be of Three Sorts, the Fixt, the Volatile, and Eſſential; The Fixt are Evidently thoſe of a Contractive Force almoſt Entirely; Volatile are the Fixt raiſed into a Degree of the Expanſive by Fire; and Eſſential are ſuch likewiſe raiſed into a certain Degree of the Expanſive by Vegetation; It was our Intention to have Examined particularly into each of theſe, in the ſame Manner, as we have done into the Spirits and Oils of the Chymiſts; as alſo into Calcination, Chryſtallization, Precipitation, Coagulation, Condenſation, Diſſolution, Rarefaction, Pulverization, Inflammation, Diſtillation, Sublimation, Digeſtion, Extraction, and Colour; and we have ſome Papers written by us Concerning ſeveral of them; we would alſo have Inquired into the Particular Conſtitution of Gold, Silver, Tin, Copper, Lead, Iron, and Mercury, into Minerals, Vegetables, and Animals, according to the Chymical way of Analyzing them; but as the Sheets would Riſe to an Expence too Great, and the Encouragement which is Given to my Proceeding in theſe Matters is too Small, and as I have Propoſed my Notions in General in this Science, which may be eaſily Purſued thro' all the Particulars Above-mentioned by a Diligent and Laborious Hand, I ſhall Excuſe my ſelf any farther Trouble on this Head, and Leaving what Remains to thoſe, who are Willing to take the Pains I have done, Go on to another Science we Propoſed to Treat of, which was Anatomy.

CHAP. III.

Concerning the Phænomenons in Anatomy, and Firſt of the Common and Proper Containing Parts of the Abdomen, *the* Cuticula, *the* Reticulum Mucoſum, *the* Cutis, *the* Membrana Adipoſa *and* Carnoſa, *the* Communis Membrana Muſculorum, *the* Peritonæum *and* Omentum.

Mr. Rolfe's Syllabus Enterologiæ, Prælect. 1.
Dr. Gibſon's Anatomy, Chap. 3. Book 1.
Dr. Keill's Chap. 1. §. 3.
Dr. Drake's Anthropologia Nova, Chap. 2. Book 1.
Blancard's Anatomia Reformata, Cap. 34. Pag. 742.

§. 1. ANATOMY may be Diſtinguiſhed into Three Parts, Enterology, Myology, and Oſteology, to each of which we ſhall Aſſign ſome Chapters, and in our Treating of Them, we ſhall Purſue the ſeveral Parts of an Human Body, according to the Order of Diſſection, and Endeavour to Explain them by our Doctrine of the Expanſive and Contractive Forces.

§. 2. THE *Abdomen* is Firſt Diſſected, as containing the Entrails, which are the moſt liable to Putrefaction and Corruption, the Integuments or Coverings of which, as alſo of the whole Body, or moſt of the Parts of it, are the Ἐπιδέρμις, the *Cuticula*, or Scarf-Skin, the *Parenchyma*, or *Reticulum Mucoſum*, the Δέρμα, or *Cutis*, the *Membrana Adipoſa* and *Carnoſa*, and the Common Membrane of the Muſcles.

§. 3. THE *Epidermis* or *Cuticula* Inveſts the whole Body, and is ſaid to be Raiſed by an hot Iron from the Heel, where it is the Thickeſt, and to be made by the *Reticulum Mucoſum*, or by a Viſcous and Oleous Vapour of the Blood, Condenſed by the External Air or Cold, or by a Tranſparent Juice Iſſuing from the Capillary Nerves, and Coagulating at the Extremities of them; Others will have it Proceed from a Seminal Principle, becauſe it is found on Infants New-Born, which cannot be owing to a Condenſation from Cold; It is more Compact than the Skin, becauſe the Serous Humour, which Paſſes thro' the Laſt is ſtopt by the Firſt, as in Puſtules and Bliſters; It is yet full of Pores for Sweat and Perſpiration, wants Nerves and Blood Veſſels, and therefore is void of Senſe, can hardly be Separated from the Skin by a Knife, but may eaſily by a Veſicatory or Cautery; It Peels off in Scarlet or Burning Fevers, and the Small Pox, but a new one Preſently ſucceeds it; It appears by Microſcopes to be made up of ſeveral Lays of Exceeding Small Scales, which Cover one another, more or leſs, according to the Different Thickneſs of the *Cuticula* in the ſeveral Parts of the Body, and in the Lips, where the Scales appear Plaineſt, becauſe the Skin is Thinneſt, they only in a Manner touch one another; Theſe Scales are ſuppoſed to be either the Excretory Ducts of the Glands of the Skin, as is thought to be Evident in Fiſhes, or elſe theſe Glands have their Pipes opening between the Scales; *Lewenhoeck* reckons, that in one Cuticular Scale, there may be Five Hundred Excretory Channels, and that a Grain of Sand will Cover Two Hundred and Fifty Scales, ſo that one Grain of Sand will Cover One Hundred Twenty Five Thouſand Orifices, thro' which we daily Perſpire; He thinks the *Cuticula* to be an Expanſion of the ſaid Excretory Ducts of the Glands of the *Cutis*, or Skin, and, as is ſaid, with Great Probability; The Humour, which is Separated by thoſe Glands, being Pent in between the Scales, cauſes frequent Itchings, to the Removing of which, Nature Directs us to Rubbing, Waſhing, or Bathing; It ſticks cloſe to the Surface of the Skin, to which it is alſo tied by the Veſſels which Nouriſh it, tho' they are ſo Small, as not to be ſeen.

IF inſtead of Raiſing it by a Cautery on a Dead Body, we Examine that, which is Raiſed by Cantharides, or any other Veſicatory, we ſhall find it to Conſiſt of ſeveral Membranes exceedingly Thin and Fine, and not deſtitute of Bodies Reſembling

Glands, which in that State are Viſible to the Naked Eye, and therefore, it is Imagin'd, muſt have Veſſels belonging to it, tho' not Diſcoverable by Microſcopes.

The Solution of the ſeveral Phænomenons of it, from the Doctrine of the Expanſive and Contractive Forces.

§. 4. THIS is a full and ſhort Account, which the Anatomiſts give of the *Cuticula*, which ſeems to Ariſe from the Expanſive Force of the Blood and Spirits on the one Hand, and the Contrary Expanſive of the Air on the other, which in Reſpect of the Former is Contractive; for from hence it follows, that a Denſe, Continued, and Membranous Subſtance will be Produced, as the *Epidermis* or *Cuticula*, namely, from Two Oppoſite Forces, which are nearly Equally Balanced, as the Expanſive and Contractive in this Caſe are, and in the *Fœtus* in the Womb, the Liquor of the *Amnion*, in which it Swims, ſupplies the Place of the Contractive; For this Reaſon it is, that ſome have Thought the *Cuticula* to be made by a Viſcous and Oleous Vapour of the Blood, others by a Tranſparent Juice Iſſuing from the Capillary Nerves, and both of them, that it is Condenſed by Cold, becauſe it is Actually formed by the Expanſive Force of the Blood and Spirits, and the Contractive of the Air Reſiſting and Repelling their Action; If the Expanſive Force on one Side is Increaſed by a Cautery or Veſicatory, or by an Inflammation, or if the Contractive of the Air is on the other Diminiſh'd, as in Cupping Glaſſes, the *Cuticula* is Raiſed and Expanded from the *Cutis*, and Bliſters and Puſtules are Cauſed; This likewiſe gave an Handle to ſome to Imagine it was Derived from a Seminal Principle, becauſe the Blood and Spirits are ſuch, and are Different and Peculiar in Men, and by Conſequence, the *Cuticula*, from what they are in Brutes; *Lewenhoeck*'s Notion alſo of it's being an Expanſion of the Excretory Ducts of the Glands of the Skin Receives from hence a Solution; It Peels off in Burning Fevers, and the Small Pox, by an Exceſs of the Expanſive above the Contractive, and is again Renewed by an Equal Poiſe of thoſe Two Forces; It is not Neceſſary, that it ſhould be full of Pores for Sweat and Perſpiration, but that it ſhould be Separable only by an Increaſe of the Expanſive Force, when the Blood and Spirits are Excited by Heat or Exerciſe; It is void of Senſe, when Divided from the Expanſive Force of the Spirits, as any other Part of the Body would be, but whilſt United with it, as in it's Natural State, it is the Inſtrument of Feeling; It's Surface conſiſts of Innumerable ſmall Aſperities, or little Scales, becauſe the Expanſive Force of the Blood and Spirits and the Contractive of the Air do not Act againſt each other by one Uniform Diffuſion, but in Punctual and Unequal Exertions, as Common Fire and Flame does, by which Liquors, in Boiling or Growing Hot, Contract a like Uneveneſs in their Surface.

THERE is no occaſion for Veſſels to nouriſh it, or Nerves to make it Senſible, all that is Required for both is it's Adherence to the Syſtem of the Expanſive Forces of the Blood and Spirits; It may be Divided into ſeveral Membranes, and may ſeem to have Glands from the Application of Different kinds of Expanſive Forces to it, as Water is Raiſed by Heat into Cuticles and Bubbles; And the *Cuticula* appears to be nothing elſe than an Animal Fluid Agitated by the Expanſive Force of the Blood and Spirits, and Condenſed and Congealed by the Contrary Expanſive or Contractive Force of the Air, and in the Womb by the Liquor of the *Amnion*; which ſhews the wonderful Providence in Nature, in Preparing ſuch a Liquor, ſince, without it, the Syſtem of the Expanſive Forces in a *Fœtus* would be Diſſipated and Diſſolved, having nothing to Counter-Act to it, from whence no Production would Enſue, but an Entire Abortion and a Corruption of the whole *Fœtus*.

How Hair is Produced and the Reaſon of it's Different Colours, Curlings, and Figures.

WHERE the Expanſive Force of the Blood or Spirits is the Greateſt, by which it over-balances the Contractive of the Air, there is a Protruſion of the *Cuticula* into Hair, as near the Brain, the *Medulla Spinalis*, and the Heart, and in the Armpits, where the Contractive Force of the Air is Diminiſhed by the Continual Adheſion of the Arms to the Body, and where it is the Leaſt, as in the Hands and Feet, there is no ſuch Protruſion, or a very Small one; According to the Different Nature and Degree of theſe Expanſive Forces of the Blood and Spirits, the Colour of theſe Protruſions alter; Red ariſes from an hot Conſtitution, or from the Greateſt Expanſive Force of the Blood and Spirits; White from a Cold one, or from the Leaſt Expanſive Force of it, from whence old Men grow Grey, and younger Perſons upon a ſudden Paſſion of Fear, or by Immenſe Care or Study, by which the Expanſive Force of the Blood and Spirits is Weakened and Enervated; and Black or the Deepeſt Red from a Great Degree of the Expanſive, mixt with a Great Degree of the Contractive of the Blood and Spirits; the Firſt are conſequently, Cholerick, Briſk, and Lively in their Parts; the Second, Calm, Sedate, and Cool; and the Laſt, Melancholick, Quick, and Vigorous, but Solid, Judicious, and Grave: It is generally Streight in Cold Countries, and Curled and Contorted in Hot, becauſe the Contractive Force of the Air is more Certain, Uniform, and Determined in it's Reſiſtance in the Firſt Caſe, and more Deſultory, Various, and Unequal in the Laſt; and in the ſame Climate, where the Expanſive Force of the Blood and Spirits is leſs Regular and Uniform, the Hair from thence becomes likewiſe Curled and Contorted, and where it is Streight, it is a Sign of a Greater Certainty, Unalterableneſs, and Immutability in their Action; It is Triangular, or Four-ſquare, or Round in it's Figure, as the Expanſive Force of the Blood and Spirits Exceeds more or leſs, or is Equal to the Contractive of the Air, which ſurrounds it; if more, it Exerts it ſelf in Three Angles, if leſs, in Four, and approaches nearer to a Circle, if Equal, it is Circular.

Why Plants have Different but Regular Forms in their Leaves and Stalks.

Which alſo will give an Account of the Different Forms of Plants, and the Stalks of Them, which come nearer to a Circle, or depart farther from it, as the Proper Expanſive Forces of them, Derived from their Seminal Principle, are nearer to an Equilibrium with the Contractive of the Air, or are more Removed from it; and the Figures will be always or moſtly Regular, becauſe the Superiority of Action in the Expanſive above the Contractive of the Air muſt Exert it ſelf alike, and therefore in Three, Four, Five, or an Hundred Equidiſtant Angles from each other.

Why Men are of Different Statures from one another, and in the Various Periods of their Lives, as alſo why Animals are of Different Bigneſſes from Men.

From this Doctrine likewiſe is Determined the Different Stature and Bigneſs of Men in the ſeveral Periods of their Lives, and Compared with one another, as alſo the Various Proportions of Animals and Inſects; Thus the Expanſive Force of the Blood and Spirits in Inſects being Small, the Syſtem is Extended but a ſhort way before the Contractive of the Air becomes an Equal Balance to it; in Birds and the Smaller kind of Animals the Expanſive Force is Increaſed, by which means the Syſtem is Extended farther, before it is weak enough to be Reſiſted and Equi-Poiſed by the Contractive of the Air; and in larger Animals, as the Lion, the Horſe, the Ox, and the Elephant, the Expanſive Force of the Blood and Spirits is ſtill Augmented, from whence the Syſtem of them is more Dilated before it's Force is Diminiſhed to an Equilibrium with the Contractive; and thus it is in Men, ſo that the Greater Stature any one Acquires, it muſt be from thence Inferred, that the Expanſive Force of his Blood and Spirits is Greater, and that in young Men it is Greater than in Infants and Children, till it obtains it's utmoſt Force in Perſons of Maturity, when there is no farther Growth or Expanſion of the Syſtem, the Extreme Parts of it being in an Equal Balance with the Contractive of the Air, with which it is Encompaſs'd, or in Fiſhes with the Contractive of Water; and the ſame kind of Reaſoning obtains in Plants and Trees, if for that of the Blood and Spirits in Animals, we ſubſtitute the Expanſive Force of the Nutritious Juices and the Vegetating Quality of Them.

Why it is not Impoſſible but Men might have Gigantick Forms before the Deluge, and Plants and Animals might be Greater than we now find them.

See alſo Chap. 5. §. 46. Book 1.

Lastly, If the Expanſive Force therefore of the Blood and Spirits in Men and in Animals, and of the Nutritious Juices and their Vegetating Quality in Plants and Trees, in the Antediluvian World, was Greater than in the Preſent, and the Contractive Force of the Air Leſs, which in a Different Craſis and Temper of Things is not Impoſſible, and particularly, ſuppoſing the Surface of the Earth was much Higher and more Removed from the Center of it, when all Beings would have a Leſs Force of Gravitation and Contraction, and a Greater of Expanſion, than in this lower and more Contracted Form, it is not Inconceivable, that Men and Animals, and Plants and Trees, might be much Larger, and more Longæval and Durable, than we now find and Experience them to be, and that for ſome Ages, after the Diſſolution of the Earth's Original Frame by the Flood, ſuch Gigantick Proportions might be in ſome Degree Continued, till they ſunk in Proceſs of Time to the ſettled Standard of Magnitude and Duration, which is agreeable to the Modern Conſtitution of the Earth we Inhabit. This we ſay in Anſwer to the Cavills of Irreligious Men, who Think ſuch Matters Incredible, which do not agree with the Modern Frame and Structure of Beings.

Thus far we have conſidered the *Cuticula* of the Anatomiſts, which is the utmoſt Term and Boundary of the Animal Syſtem, and how it comes to be Defined by certain Limits from the Nature and Degree of the Expanſive Force of the Blood and Spirits, and the Contractive of the Air, which hinder it's Dilatation *in Infinitum*.

§. 5.

§. 5. THE next Subſtance, which lies Immediately under the *Cuticula*, and above the *Cutis*, or Skin, is the *Reticulum Mucoſum*, or *Parenchyma*, which in the *Europeans* is a White Slime, and in the *Æthiopians* a Black, ſcraped off from the Inner Side of the *Cuticula* Raiſed, and which ſerves to fill up the Interſtices made by the *Nervous* or *Pyramidal Papillæ*, Jetting out from the Surface of the *Cutis* or Skin; Of which there is little more to be ſaid, excepting, that it ſeems to be a Matter Prepared for a ſupply of the *Cuticula*, upon any Accidental Defect of it, that it is thrown out from the Expanſive Syſtem of the Blood and Spirits, as an Excrement of it, and more particularly from the *Nervous* Juice, which is of a Contractive Nature, and therefore more eaſily ſubmits to the Contractive Force of the Air, when it is Expoſed to it, which Blood, or Fat, or Spirits, would not do, and conſequently is Immediately Condenſed by it.

Concerning the Reticulum Mucoſum, *or* Parenchyma.
Syllabus Enterologiæ.

Dr. Keill's §. 4. Chap. 1.
Dr. Drake's Anthropologia Nova, Chap. 3. Book 1.
Blancard's Anatomia Reformata, Cap. 34. Pag. 742.

§. 6. THE *Cutis* or Skin, beſides it's own Proper Subſtance, which is made up of *Nervous Fibres* very cloſely Interwoven one with another, and of a *Parenchyma*, which fills up the Inequalities and Interſtices thereof, has it's *Nervous* or *Pyramidal Papillæ*, which are ſmall Strings ſeen to break off by pulling the *Cuticle* from the *Cutis*, and are thought by *Malphigius* to be the Ends of the Nerves Perforating the Skin, and not Raiſed from the Skin's proper Subſtance, but theſe *Pyramidal Papillæ* cannot be ſeen without Optick Inſtruments, and can hardly be ſhewn by the Common way of Diſſection; It has alſo, lying betwixt the ſaid *Papillæ*, the *Glandulæ Miliares*, or *Sudoriferæ*, which Convey the Sweat thro' the Skin, and Separate it for it's Excretion; It has likewiſe certain Bulbs or Protuberances, in which the Roots of the Hair are fixt, and it's Veſſels are *Sanguineous*, *Nervous*, and *Secretory*; It is Thin in the Forehead and Sides, and under the Heel it is Thickeſt; It is Thinner in Children and Women than in Men, and in thoſe that Live in Hot Countries, than thoſe that Live in Cold; From whence, according to *Spigelius*, thoſe who are born in Cold Countries, when they come under the Equinoctial Line, are often taken with Fevers, becauſe the Great Heat there Excited in the Body by the External Air cannot Exhale thro' the too Thick Skin; It is Imagined to be full of Pores, and that thoſe, who Deny them, oppoſe not only Reaſon but ocular Demonſtration; the Paſſing of Quick-ſilver thro' a Sheep-skin, we are Told, Evidences this, and that Mr. *Boyle* has Tried the ſame in a Piece of the Skin of a Man's Arm, and this is ſtill farther Proved, it is Thought, by the Iſſueing out of Freſh Sweat from a Man's Fingers, when the Former is wiped off; It is ſaid to be of a moſt Exact Temperature, neither too Hot, nor too Cold, that it might judge more Accurately of the Temperature of Tangible Things, It's Nervous Part, which is naturally Cold, being ſomething Warmed by the Arterial Blood, for it has many both Capillary Arteries and Veins Diſtributed thro' it, as alſo abundance of Nervous Twigs, which Endue it with a moſt Exquiſite Senſe; Each of the Miliary Glands Receives a Nerve and an Artery, and ſends out a Vein or Excretory Veſſel, which laſt Paſſes to the *Cuticula* for the Diſchargeing the Matter of Sweat and Inſenſible Perſpiration, and for the Moiſtening the *Cuticula*, and the *Pyramidal Papillæ*, that they may not be Dry, which would very much Hurt the Senſe of Touching; The Skin is Six Times Thicker than the Scarf-Skin, and ſerves for an Emunctory of the whole Body, and it is ſaid, that the Sum of the Particles, ſtrained thro' the Cuticular Glands, is by *Sanctorius* reckoned to amount to about 50 Ounces a Day, ſo that, ſuppoſe a Man's Body to weigh 160 Pounds, in 51 Days we Perſpire a Quantity Equal to the Weight of the whole Body, but in what Time, or if ever, the whole Subſtance of the Body is Changed, is no Eaſy Matter to Determine. And thus far the Anatomiſts.

Concerning the Cutis, *or Skin, with a particular Account of it, Extracted from the Anatomiſts.*
Syllabus Enterologiæ.
Dr. Gibſon's Anatomy, Chap. 3. Book 1.
Dr. Keill's §. 4. Chap. 1.
Dr. Drake's Anthropologia Nova. Chap. 3. Book 1.
Blancard's Anatomia Reformata, Cap. 34. P[illegible] 742.

§. 7. THE Expanſive Syſtem of the Blood and Spirits, being now Freed from the Impreſſions and Contractive Force of the External Air, is more at Liberty to Exert it's own Actions.

A Solution of the Preceding Phænomena of the Cutis *from the Doctrine of the Expanſive and Contractive Forces.*

AND Firſt, the Syſtem of the Spirits or the Nervous Fluid Expanding it ſelf, as far as it can, is ſtopt at the *Cuticula* by the ſaid Contractive Force of the Air, and from thence Divaricates into a Thouſand Streams Croſſing and Interſecting each other, which Conſtitutes the Subſtance of the Skin, and Forms thoſe Nervous Fibres, of which it Conſiſts, and which are ſo cloſely Interwoven one with another; Hence alſo come the *Pyramidal Papillæ*, and the ſmall Nervous Strings, which break off by Pulling the *Cuticula* from the *Cutis*; On the other Hand, the Syſtem of the Blood, *How the Nervous Fibres, the Arteries, and Veins of it are Formed, as to the Various Rivulets of the Fluids.*

Expanding it's ſelf likewiſe, is ſtopt at the *Cuticula* and the Contractive Force of the External Air, and made to Diffuſe it's ſelf into Innumerable Rivulets, which Compoſe the Blood Veſſels, and which are Diſperſed by that means thro' the whole Skin, and thus all the Arteries of it ſeem to be Formed, in which the Blood Retires from the Heart; This Expanſive Force of the Syſtem of the Blood continuing, and the Blood not being able to Proceed any farther, is by it's ſaid Expanſive Force Returned back and Repelled from the *Cuticula*, and the Contractive Force of the Air, towards the Heart, by which the Veins are Produced; But the Nervous Fluid, being of a Cold and Contractive Nature, Terminates in the Skin, without any Circulation, or Recourſe, or Repulſe from it.

Whence Sweat ariſes, and how made from the Contractive Force of the Nervous Fluid being Weakened.

INTERMEDIATE to the *Pyramidal Papillæ* Lie the Miliary or Sudoriferous Glands, and the Mouths of the Ducts, which open into them, and which are made by the Sweat; which ariſes from a Conteſt betwixt the Contractive Force of the Spirits, or the Nervous Syſtem, and the Expanſive of the Blood; for tho' they are both of them taken together of an Expanſive Nature, in Reſpect of the External Air, yet in Compariſon with each other, the Nervous Syſtem is of a Cold or a Contractive Temperature, and the Blood of an Hot or an Expanſive; and therefore it is, that all Heat Diſſolves and Enfeebles the Nerves and Spirits, and all Cold Contracts and Envigorates them; And on the Contrary, all Heat Excites and Inflames the Expanſive Force of the Blood, and all Cold Weakens and Impairs it: When theſe Two Syſtems are Equally Balanced, the whole Human Frame or Compoſition is in Exact Order; but if the Expanſive Force of the Blood is too much Increas'd by Exerciſe or Heat, or the Contractive Force of the Spirits is too much Diminiſh'd by Labour or the Depreſſion of them, as in Faintings, or in Sleep, Sweat Enſues; which is neither a Nervous nor a Sanguineous Fluid, but a Nervous Weakened and Diſſolved, by which it becomes more Liquid than the Nervous, but Retains a Degree of it's Contractive by it's Saltneſs, as all Salts are of a Cold and Contractive Temper.

How it Paſſes thro' the Cutis.

AND from hence it is, that the Sweat can Force it's way thro' the Subſtance of the *Cuticula*, without the Suppoſition of any Pores in it, when the Nervous Fluid and the Blood cannot; becauſe the Nervous Fluid is of too Contractive, Conſiſtent, and Cold a Nature to do it, and the Blood's Expanſive is Reſiſted and Repelled by the Contractive of the Air; whereas the Sweat, being a Contractive Excited by the Expanſive of the Blood, is Leſs oppoſed by the Contractive of the *Cuticula* and the Air, and, Approaching more to it's own Nature, is more eaſily Admitted and Received by it.

THUS far we have Conſidered the Fluids, which Enter into the Skin, of which the Firſt or the Nervous is ſenſible, and ſeems to be of the like Subſtance with the Brain, and to be ſeveral Proceſſes from it, but the Blood and Sweat do not appear to be Endued with that Power.

How the Coats of the Veſſels, or the Solids, in the Cutis *are Produced.*

THE next Thing to be Examined and Accounted for is the Solids, which are made up of the Veſſels, which Contain and Circulate, or Secrete the Fluids, and are Derived from the Contractive Force of the Nervous Fluid, and the Expanſive of the Sanguineous; for as the *Cuticula* is Formed from the Expanſive Force of the Animal Syſtem and the Contractive of the External Air, which Acts againſt it, ſo by the Expanſive Force of the Blood being Acted againſt by the Contractive of the Nervous Fluid, the Coats of the Blood Veſſels are Produced, and thoſe of the Nerves by the Expanſive Force of the Blood, and the Heat ariſing from it, Acting againſt the Contractive of the Nervous Fluid; from which Contractive Force it is, that they and all the Membranes of the Body are ſaid to Deduce their Original from the *Meninges*, or the *Pia* and *Dura Mater* of the Brain, and from whence they come to be Furniſhed with ſuch an Exquiſite Senſe; Thus alſo we ſee, by the Expanſive Force of Fire and the Contractive of Water Acting againſt each other, a Film or ſmall Membrane is Conſtituted and Framed.

How the Circulations of the Fluids in the Cutis *and the Animal Syſtem are Performed by the ſame*

To theſe Two Oppoſite and Contending Forces is likewiſe owing the Circulation of the Fluids in the Skin, and thro' the whole Body; and the Revolutions of the Humours in the Animal World are Accounted for in the ſame Manner, and upon the ſame Principles of the Expanſive and Contractive, as thoſe of the Heavenly Bodies in the Material; For the Contractive Force in the Nervous Syſtem, to which is annext the Expanſive Force of Senſe or Intelligence, Acting continually againſt the Expanſive in the Sanguineous, which in Reſpect of the Mind is Contractive, is the ſame, as the Almighty Intelligence and the Expanſive of the Sun Acting againſt the Contractive of a Planet; for the Action of the Mind or of Senſe being Superior in the Nervous Syſtem, ſince the Counter-Action, or Contractive Force, in the Sanguineous cannot prevail againſt it, it muſt Circulate about it, for the ſame Reaſon, as a Planet about the Sun; Thus, The Blood Acts by it's Force againſt the Nervous Coats of the Veſſels, which Contain it, and the Nervous Coats Contract themſelves againſt that Force, which, being too Weak to Reſiſt the Contraction, Proceeds forwards in the Arteries, from whence ariſes the Progreſs of the Fluid in it's Proper Channel, and the Pulſation, by which it is Promoted; From hence alſo it is, that every Artery has a Nerve, which Attends it, to fortify and ſtrengthen the Contractive Force of the Nervous Syſtem, in order to Propagate the Motion of the Sanguineous, and the Blood is carry'd back without the Aſſiſtance of ſuch Contraction, by Protruſion only thro' the Veins, and by Valves, which hinder it's Regreſs, and therefore has no occaſion of ſuch Nerves to accompany them, nor is there found any Pulſation in Them.

Laws, as thoſe in the Heavens, namely, of the Expanſive and Contractive Forces.

THUS Rivers alſo are Probably made to Circulate about the Earth by an Oppoſition betwixt the Expanſive and Contractive Forces; for Water having an Expanſive Force in Reſpect of Earth, which is Evident from it's being eaſily Raiſed into Exhalations and Vapours, would Exert it's Activity that way, if it were not ſurmounted by the Contractive of the Earth, which therefore ſpends it ſelf Side-ways by a Revolution round it; ſince, if there was nothing, but the Gravitation of it, it ſhould Tend to the Center and be bound down towards it in a Perpetual Stagnation, unleſs we ſuppoſe a Declivity in the Channel, which is not Evident in a Sphere, as the Earth.

That Rivers Circulate about the Earth the ſame Way.

THE Thickneſs or Thinneſs of the Skin depends upon Two Cauſes, the External Air, and the Internal Syſtem of the Blood and Spirits; The Greater the Contractive Force of the Internal Syſtem is in certain Parts, the Thicker will the Skin be, and the Greater the Expanſive, the Thinner; 'tis Thickeſt therefore in the Head and Back, becauſe it lies next to the Brain, and the *Medulla Spinalis* or *Oblongata*, which are Cold and Contractive, and under the Heel, becauſe the Expanſive Force of the Blood is Leſs in thoſe Parts; In the Fore-head, Palm of the Hand, and Lips, it is Thinneſt, becauſe the Contractive Force is Leaſt there from the Brain and Nerves, and the Expanſive the Greateſt from the Blood, as is Evident from the Redneſs and Floridneſs we obſerve in Them; And thus it is Thinner in Children and Women than in Men, becauſe the Expanſive Force of the Blood Prevails moſt in the Firſt, and the Contractive of the Nervous Fluid in the Laſt, as is Manifeſt from the Weakneſs, Beauty, and Sanguine Colour of the one, and the Strength, Robuſtneſs, and the Paler or Duller Complexion of the other; But there is likewiſe another Cauſe of this, which we before-mentioned, namely, the External Air, for the more Cold and Contractive the Temper of that is, the Skin will be thereby made Thicker, and the more Warm and Expanſive, the Thinner; Men therefore being more Expoſed to the Cold and the Contractive Force of the Air than Women or Children, their Skin is upon that Account more Denſe and Thicker, and for the ſame Reaſon Their's who Live in Colder Climates, than Their's who Live in Hot ones; And, that an Expanſive Force of Blood or Heat ſhould Diſſolve Continuity, and a Contractive one of the Nervous Juice or Fluid, or of Cold in the External Air, ſhould Contribute to it and Increaſe it, is not any ways hard to Imagine.

The Cauſe of the Different Thickneſs and Thinneſs of the Cutis *Derived from the ſame Principles.*

As to the Pores of the Skin there is no occaſion for them, as we have ſhewn there is not in the *Cuticula*, ſince the Conſiſtency of it is ſuch, as to Permit a Paſſage to any Forces, which it is convenient to Nature ſhould be Tranſmitted thro' it, and it is Confeſſed, that the Famous Dr. *Gliſſon* denied any ſuch Pores to belong to it; Thus a Pin or a Needle can make it's way thro' a Solid or a Fluid, when Acted with a ſufficient Force, and there is no Greater Difficulty in Apprehending, how any Fluid of the Body ſhould obtain the ſame Effect in Reſpect of the Skin, where it is Expelled by the Expanſive Force of the Animal Syſtem and Protruded thro' it, which is the Caſe of Sweat, and therefore can be no Proof of ſuch Pores; and as for Quick-ſilver Paſſing thro' a Sheep-Skin, or the Skin of a Man's Arm, it is only an Evidence of what I have been Affirming; Beſides upon ſome Extraordinary Strainings even Blood has Iſſued thro' the Skin, for which yet it never was ſuppoſed, that any Pores were Formed, and conſequently, it's very Subſtance muſt be capable of Yielding

Not neceſſary that there ſhould be any Pores in the Cutis, *the Tranſmiſſion of Sweat being otherways Accounted for.*

ing to and Allowing the Tranſmiſſion of a Force, which is Superior to it, that is, of an Expanſive Superior to it's Contractive.

Concerning the Fat, the Membrana Adipoſa, and Muſculoſa, with a Summary Account of Them.

Syllabus Enterologiæ. Dr. Gibſon's Anatomy, Chap. 3. Book 1. Dr. Keill's Chap. 1. §. 6. and 7. Dr. Drake's Anthropologia Nova, Chap. 4. Book 1. Blancard's Anatomia Reformata, Cap. 18. Pag. 392.

§. 8. UNDER the Skin lies the *Membrana Adipoſa*, in the Cells of which the Fat is Contained, and which is allowed to be of an Oily Subſtance Condenſed by Cold, with which the Membranous Cells are filled, as the Cells in the Pulp of an Orange are filled with it's Juice; and Dr. *Gliſſon* ſays, that the *Membrana Adipoſa* is a Part of the *Carnoſa*, the outer Part of which is full of ſuch Membranous Cells; *Malpighius* Informs us, that the Blood Veſſels are Expanded like the Boughs of Trees every where thro' the Membrane, that lies under the Fat, and the Membranous Cells, full of Fatty Globules, Veſicles, or Bladders, hang upon their Ends, like Leaves upon the Boughs; The Cells are of almoſt an Oval Figure, and are like the Lobules of which the Lungs are Compoſed, or rather like a Conglomerate Gland; They are Knit to one another by the Membrane, out of which they are Formed; and thro' the ſame Membrane and Cells, not only Capillary Veins and Arteries, but *Ductus Adipoſi* alſo Run, which Swell with Fat, eſpecially in an Animal newly Killed; This Fatty Membrane Extends it ſelf all over the Body, except in the Lips, the upper Part of the Ear, the Eye-lids, and Fore-head, and ſome few other Places, and the Fat is ſuppoſed to be Bred of an Oily or Sulphureous Portion of the Blood, Sweating, like a Dew, out of the Veins, and afterwards Concreting; It is Different from the Suet or Tallow of the *Omentum* or Caul, in this, that Fat is eaſily Melted, but not ſo eaſily Congealed, whereas Suet is not eaſily Melted, but is eaſily Congealed, Fat is not Brittle, but Suet is; ſome Reckon the Marrow of the Bones to be a Third ſort of Fat. It Defends the Body from the External Air, Preſerves the Natural Heat, Hinders the too Great Diſſipation of Spirits, Fills up the Interſtices of the Muſcles and Wrinkles of the Skin, and thereby Contributes to the eaſy Motion of the Former, and to the Beauty of the Latter, and keeps all Parts from Dryneſs and Breaking; It Beſmears the Extremities of the Cartilages, the Jointings of the Greater Bones, and the Veſſels, that they may Paſs ſafely; *Malpighius* thinks the Principal uſe of it, whilſt it is mixt with the Blood, is to be a continual *Pabulum* or Food of the Natural Heat, whereby the Vital Flame is Perpetuated, Alſo to mitigate the Acrimony of the Blood, and unite the Saline Particles of it, ſo as they may become Aſſimilable to the Solid Parts for their Nutriment, ſerving to thoſe Particles, as Oil to Colours in Painting, or Lime to Stones in Building, and that in Caſe of Famine it Paſſes into the Nouriſhment of the Body, ſo that ſome Creatures Live during a whole Winter without any other Food, and an Atrophy never becomes Mortal, till all the Fat is Waſted; In this Membrane are alſo a Number of Little Glands, which are accompany'd with Lymphatick Veſſels, which carry back any Seroſity, that is, Superfluous; In ſome the above-mentioned Veſicles are ſo full, that the Fat is an Inch, or an Inch and half Thick, and in others they are almoſt Flat.

The ſeveral Kinds of Fat, and it's Uſes, according to Anatomiſts.

What a Membrane is, and the ſeveral Sorts of Them.

MEMBRANES are Webs of ſeveral Sorts of Fibres Interwoven for the Covering and Wrapping up of ſome Parts; Their Membranous Fibres give them an Elaſticity, whereby they can Contract and cloſely Graſp the Parts they Contain, and their Nervous Fibres give them an Exquiſite Senſe, which is the Cauſe of their Contraction, therefore they can ſcarcely ſuffer the Sharpneſs of Medicines, and they are Difficultly united, where there is a Solution of Continuity, or Loſs of their Subſtance; In their Texture there are a Number of ſmall Glands, which ſeparate an Humour fit for Moiſtening the Parts, which they Contain; Thoſe that Cover the Solid Parts are properly called Membranes, as the *Peritonæum*, which Wraps up all that is Contained in the *Abdomen*, the *Pleura*, that, which is in the *Thorax*, the *Perioſteum* the Bones, and the *Pericardium* the Heart; Thoſe, which Form the Coats of Veſſels, and which Contain the Humours, as thoſe of the Veins, Arteries, Stomach, Bladder, Inteſtines, *&c.* are called Tunicles or Coats, and thoſe, which Cover and Embrace the Brain, as the *Dura* and the *Pia Mater*, are called *Meninges*; of all theſe Kinds of Membranes ſome are Thin and ſome are Thick, and the ſame Membrane is Thick in ſome Places and Thin in other, as the *Membrana Adipoſa*, which is Thicker in the Neck than in any other Part of the Body; The uſe in General of Membranes is to Cover and Wrap up the Parts, to Strengthen them, to Save them from External Injuries, to Preſerve the Natural Heat, to Join one Part to another, to Suſtain ſmall Veſſels and the Nerves which Run thro' their Duplicatures, to ſtop the Returning of the Humours in the Veſſels, as the Valves ſtop the Returning of the Blood in the Veins and Heart, of the Chyle in the Lacteals and Thoracick Duct, and of the *Lympha* in the Lymphatick Veſſels.

By the *Membrana Adipoſa* is moſt commonly underſtood that Part of it only, which lies next the Fleſh, and which contains but little Fat in it's Cells, and therefore Appearing more Membranous than the Reſt is ſaid to be the Baſis of the *Cellulæ Adipoſæ*, and even ſome Part of this hath been taken by Anatomiſts for the *Membrana Carnoſa* upon the Account of it's Redneſs, for here the Blood Veſſels lie very Thick, the Veſicles not being Diſtended with Fat.

The Fat, which is a Groſs Whitiſh Oil, is nothing but the Oily Part of the Aliment ſeparated from the Arterial Blood by the Adipoſe Glands, and carry'd by Peculiar Ducts to the Membranous Cells, from whence it is Tranſmitted to the Blood again by the Veins; In Corpulent Perſons, who have their Blood too much Charged and all their Organs too much Clog'd with it, Senſation is Dampt, and they are apt to fall into a Drowſy Lethargick Condition, which ſometimes Ends in ſudden Death, and the Abundance of it ſeldom fails of being Attended with Inactivity and Somnolency.

Under the *Membrana Adipoſa* lies the *Membrana Communis Muſculorum* or *Muſculoſa*, and makes a Duplicature with it; It is Spread all over the Body, except the Skull according to ſome; It is Knit by Fibres to the Adipoſe Membrane that lies above it, and to the Proper Membrane of each Muſcle that lies under it; 'Tis Thin, but Strong, 'tis not Yellow like the Adipoſe, but Whiter and more Tranſparent, and is ſaid by Dr. *Havers* in his *Oſteologia Nova* to be every where Glandulous, by which a Mucilaginous Liquor is Diſtilled upon the Muſcles to Lubricate them; Theſe Membranes receive Veins, Arteries, and Nerves from the Parts which are neareſt to them; As to the *Membrana Carnoſa*, which lies in Brutes betwixt the *Adipoſa* and *Muſculoſa*, It ſeems to be the Cauſe, by it's Expanſive Force, of that General Protruſion of Hair thro' the whole Body, according to the Explanation given §. 4.

How the Adeps or Fat is formed from the foregoing Principles.

§. 9. This being a full Account from the Anatomiſts of the Fat and the Membranes, which lie under it, we ſhall now Conſider them one after another; As to the *Adeps* or Fat, it ſeems to be Formed from the Expanſive Force of the Blood, brought by the Arteries to the Adipoſe Membrane, according to *Malpighius*, and there Meeting with the Nerves, which contain a Contractive Subſtance, there being a Duplicature of Membranes alſo, the upper Red, where the Blood Veſſels Run, and the lower White, where the Nervous ones are Spread and Diffuſed, from their Mutual Action upon each other an Intermediate Liquor is Produced, not ſo Red as Blood, nor ſo White as the Nervous Fluid, not ſo Hot and Warm as the Former, nor ſo Cold and Phlegmatick as the Latter, from whence a Pale Yellowiſh Oil ſucceeds, and which we have before ſaid appears to be the Nature of Sweat, which is an Exuding of this Oil.

How the Veſicles, in which the Fat is Contain'd, are Produced.

The Bubbles and Veſicles are made by the Two Contending Forces, as is done by Heat and Water mixing together, or in the Pulp of an Orange by the Sun's Expanſive Mingleing with the Cold and Contractive Juice of the Fruit and Tree; The Expanſive alſo Exerts it ſelf ſtill in ſome Meaſure in the Oil, and Forms the Contractive into the Bladder or Film, which ſurrounds it, to which the Contractive Force of the External Air, which Penetrates by it's Contrary Expanſive, we may eaſily Imagine, thus far, is Aſſiſtant, and Helps to Conſtitute theſe Veſicles, as it manifeſtly does in the Formation of other Bubbles; and they are like the Lobules, which Compoſe the Lungs, or like a Conglomerate Gland for the ſame Reaſon.

Why no Fat in the Lips, the upper Part of the Ear, &c.

There is no Fat in the Lips, the upper Part of the Ear, the Eye-lids, and Forehead, becauſe in theſe Parts the Contractive Force of the Air, or the Expanſive Force of the Blood is too Great, or the Contractive Force of the Nervous Fluid too Small to Produce a due Mixture for Fat, or a Conteſt or Ebullition betwixt thoſe Forces, which is Requiſite to the Attemperature of the Oil, and the Raiſing of the Globules and Veſicles; hence alſo there is a Sulphureous Quality in the Fat from the Expanſive Force of the Blood, and a Cold or Condenſing one from the Contractive of the Nervous Fluid and of the Air.

How this Account agrees with what we gave before of Chymical Oils.

This likewiſe Agrees with the Account, which we before gave of Chymical Oils, which follow the Spirits, which are of an Expanſive Nature, and riſe before the Phlegm, and the other Principles, which are of a Contractive; ſo that it is a Force

Intermediate to and Compounded of the Expanſive and Contractive, according to what is here Affirmed and Maintained.

Confirmed by Dr. Grew's *Experiment.*

BESIDES which, Dr. *Grew*'s Experiment, quoted by Dr. *Havers* in his *Oſteologia Nova* and his Diſcourſe therein of the Marrow, Admits from what foregoes of a Solution; which Experiment is to ſhew us, how we may Imitate the Fat of an Animal Body: Take Oil Olive, and pour it upon High Spirit of Nitre, then Digeſt them for ſome Days, by Degrees the Oil becomes of the Colour of Marrow, and at laſt is Congealed or Hardened into a White Fat or Butter, which Diſſolveth only by the Fire, as that of Animals, and it hardens moſt upon the Exhalation of ſome of the more Sulphureous Parts of the Spirit of Nitre; from whence the true Congealing Principle is a Spirit of Nitre, and the Making of Fat is but the durable Congelation of Oil, and Animal Fat, but the Curdling of the Oily Parts of the Blood, either by ſome of it's own Saline Parts, or by the Nitrous Parts of the Air mingled therewith.

THUS far Dr. *Grew*, in which Experiment we have all the Ingredients, which we ſuppoſe to be in Animal Fat; for Oil Olive, being a Vegetable Oil, and Convertible into Flame, has Evidently a Sulphureous and Expanſive Nature, which likewiſe is in a Different Degree in the Blood, Spirit of Nitre from it's Salt and Cold has a Contractive Nature, tho' Actuated and Excited by Fire into a Spirit, Anſwerable to the Contractive Temper of the Nervous Fluid, which is alſo of a Cold Complexion, but Raiſed and Animated by the Mind, and to which is joined the Elaſtick and Contractive or Contrary Expanſive of the Air; It Diſſolves by the Fire, becauſe the Expanſive by that means prevails againſt the Contractive, and hardens by an Exhalation of the more Sulphureous or Expanſive Parts of the Spirit of Nitre, becauſe the Contractive then Prevails againſt the Expanſive.

And by the Difference between Common Fat, and the Sevum *of the* Omentum *or Caul.*

FRON whence we may Conclude, that the Common Fat of the Body has more of the Expanſive Force of the Blood in it, and leſs of the Contractive of the Nervous Fluid, and that the *Sevum* of the *Omentum* or Caul, has more of the Contractive Force of the Nervous Fluid in it, and leſs of the Expanſive of the Blood, becauſe the Firſt is hardly Congealed, and the Laſt as difficultly Melted; The Firſt is not Brittle, but Fluid, from the Expanſive Force, the Laſt is, from the Contractive; The Artificial Oil or Fat is Whiter than the Animal, as Oil Olive is much Whiter than Blood, which is a Deep Red, and the Nervous and Nitrous Fluids not extremely Different, or not to ſuch a Degree; Here is therefore no Occaſion to ſuppoſe any Oily Parts of the Blood, nor any Saline Parts of it, but to take the Expanſive or Sulphureous Force of the Blood it ſelf, and the Saline or Cold and Contractive of the Nervous Fluid to form this Production.

The Effects and Uſes of the Fat Conſonant to the Account we have given of it.

HITHERTO we have Conſidered the Nature of the Animal Fat, and are now to Examine the Uſes and the Effects of it; It Defends the Body from External Air, for Penetrating thro' the *Cuticula* and Skin, it is met and oppoſed by the Blood and Spirits, from which very Conteſt or Mixture the Fat and it's Veſicles are Produced, as we before obſerved, and therefore it is not reaſonable to Think it can go much farther, beſides the very Nature of Oil is in ſome Meaſure Reluctant to the Impreſſions of Air, the Firſt being Expanſive, and the Laſt Contractive; by being of a Middle Temper betwixt Blood and the Nervous Fluid, that is, by being neither too Hot nor too Cold, it is well Fitted to Lubricate, Supple, and Moiſten the ſeveral Parts; but as to it's being a *Pabulum* or Food for the Blood, before it's Secretion out of the Maſs of it, is not ſo Evident, becauſe it is not Manifeſt, that it is not made, as above-mentioned, by a Mixture of the Blood and the Nervous Fluid Principally; After which, as in Famine or an Atrophy, it is not unlikely, but it may be Converted to ſuch a *Pabulum*, it being eaſy to Imagine, that the Oil by Increaſing the Expanſive in Circulation may be Changed into ſuch a Subſtance; That Fat ſhould Incline Men to be Lethargick, and to a Somnolency, is no Wonder, according to the Account we have Given of it, ſince it Ariſes from the Contractive Force of the Nervous Fluid, being Diminiſhed by the Expanſive of the Blood, but by how much more the Force of the Spirits is Depreſs'd, by ſo much Greater muſt the Propenſity be to Drowſineſs and Sleep, thus the Expanſive Force of Fire, Wines, and Strong Liquors Acting upon the Contractive Force of the Nervous Fluid, Produces the ſame Effect, and all Narcoticks, which are of an Hot and Expanſive Nature; and therefore it is, that when we are Warm in our Beds, that is, when the Nervous Fluid and it's Contractive Force is in ſome Meaſure Diſſolved by the Expanſive of Heat, we ſink into Slumbers, which are not ſo readily Induced upon us, when we are Cold in Them; And on the Contrary, Froſt and Cold Agreeing with and Exciteing the Contractive Force of the Nervous Fluid, the Mind is Exhilarated and Enlivened by it; By the Firſt the Nerves Tremble and are Enfeebled, and by the Laſt Envigorated and Strengthened.

Why Fat Perſons are leſs Active and Lively in their Minds.

HENCE alſo it is, that where the Veſicles are Flaccid, and where Men are of a Thin and Lean Complexion, the Contractive Force of the Nervous Fluid is too Strong and Powerful for the Expanſive of the Blood, which therefore is not capable of Diminiſhing it's Force, ſo as to Produce an Oil, or a Fat, or very Little, which is the Reaſon, that Perſons of ſuch a Craſis and Temper are generally more Quick and Lively in their Senſe, than others, who are more Fat and Corpulent.

How the Membranes of the Body are Formed.

§. 10. AFTER the Fat, we are to Examine into the Adipoſe Membrane, and the other Membranes of the Body, which are formed chiefly by the Cold and Contractive Force of the Nervous Syſtem, from whence is Derived their Solidity and Continuity; This is Evident from the Web of Nervous Fibres, which Conſtitute them and from their Elaſtick and Contractive Force, ſuch as we Experience in an Elaſtick, Froſty, and Cold Air, as alſo from their Exquiſite Senſe; And as the Expanſive Force contributes to Fluidity, and to a Diſſolution of Parts from each other, when joined together by the Contractive Force, ſo the Contractive Force Cements, Unites, and Continues Them, when Diſſolved and made Lax by the Expanſive.

Why the Parts of a Membrane upon a Separation of them are difficultly United, and in General why Hard Bodies are, but Soft or Fluid ones not.

THIS Contractive Force, by which every Part Contracts towards it ſelf, and it's own Center, makes them upon Separation to be difficultly United, whereas the Expanſive Force Tending from it ſelf, and it's own Center, to that of another, Renders the Cement and Union more eaſy, becauſe there is an Inclination to it; Hence a Fluid, as Water, readily Unites, but Ice, which has a Contractive Force, do's not; The Contractive Force, which is Endued with an Elaſtick, as Glaſs, or Ice, or the String of an Harp or a Violin, Reſults to any Impreſſion from the Expanſive it has Joined to it, by which it Cloſes with any Expanſive Force or Percuſſion, which is Impreſſed, But if the Contractive Force is Broken or Interrupted, it is hard to Unite it upon the Account of it's Contractive Quality; And thus it is in the Human Syſtem, a Membrane or a Fibre, which has a Contractive Force is not eaſy to be Cemented, but a Fleſhy Subſtance, which conſiſts of an Expanſive Force of the Blood, and approaches towards a Fluidity, endeavours at a Re-union; and Bodies, which have a Contractive Force, as Glaſs, Ice, *&c.* are Cemented only by Introducing an Expanſive, and Melting them again into a Fuſion, but then after this Re-union, it is the Cold or Contractive Force, which gives them their Solidity and Tenacity, by which they become leſs Penetrable to any Expanſive Force or Impreſſion made upon them; From whence it follows, that there muſt be a Warmth or Expanſive Force from the Sanguineous Syſtem, to diſpoſe the Parts of a Membrane to a Union with each other, and a Cold and Contractive Force from the Nervous Syſtem, to make them Solid, Senſible, and Tenacious, and which in Fact and Experience is the Frame and Compoſition of a Membrane, which has it's Nerves, it's Fibres, and it's Blood Veſſels, and a Cold and Contractive Force attending the one, and an Expanſive and Warm one, the other.

THIS gives a Solution, as before, why Anatomiſts have Thought, that all the Membranes and Coats, diſperſed thro' the Body, owe their Origine to the *Meninges*, or the *Pia* and *Dura Mater*, ſince it is manifeſt, that the Brain, and the Nervous Syſtem Derived from it, has a Peculiar Efficiency in Forming of Them.

The Grand Cauſe of all the Motions in the Animal Frame is the Contractive Force of the Nervous Syſtem, and the Expanſive of the Sanguineous.

WE are likewiſe by this Theory Informed of the Grand Cauſe of all the Motions in an Animal Body, namely, the Contractive Force of the Nervous Syſtem, and the Expanſive of the Sanguineous; for we have before *Chap. 6. §. 20. Book 1.* ſhewn it to be an Univerſal Law of Nature, that where Two oppoſite Forces Subſiſt and Act againſt each other, the Conteſt or Motion will be continued, till the one or the other Prevails, and if the Forces are in an Equal Balance, the Motion will become Perpetual, till that Æquilibrium is Deſtroyed; Thus the Heart and the Brain are the Two Chief Seats of the Expanſive and Contractive Forces, and are joined to each other, and to all the Parts of the Body by Innumerable Arteries ſent out from the Firſt, and by Nerves from the Laſt; Theſe Act againſt one another by their Expanſive and Contractive Forces, and Produce the Circulations obſervable in the Human or Animal Frame; and if the Expanſive Force of the Blood is too much Increaſed by Heat or Violent Exerciſe, or High Meats, or Spirituous Liquors, the Contractive Force of the Brain, or the Nervous Syſtem, Languiſhes, and if the Contractive Force of the Brain and the Nervous Syſtem is too much Promoted by Cold Applications of Air or Water, and by a Thin and Meagre Diet, Rheums, Catarrhs, Defluctions, and Agues are Cauſed, by which the Expanſive Force of the Blood is Diminiſhed; and nothing Tends more to Health, than the Preſerving both theſe Syſtems in a due and regular Poiſe with each other, and in which Conſiſts the whole Art and Science of Phyſick, after we have Conſidered the Nature of the Mind.

Not Improbable that the Semen *of the Male Parent is the Source of the Contractive and the* Ovum *of the Female, of the Expanſive.*

IT is not farther Improbable, that the Principles of the Brain in the *Fœtus* are Derived from the *Semen* of the Male Parent, which ſeems to be a Matter Endued with Senſe, as the Brain and the Nervous Fluid is, and has been Obſerved by *Lewenhoeck* to be made up of Millions of Animalcules; This therefore Impregnating the *Ovum* of the Female Parent, which we may juſtly ſuppoſe is of a Warm and Expanſive Nature, Firſt cauſes that Beating Red Speck, which Anatomiſts have Imagined to be the Heart; from which Two Subſtances, mixt in the *Ovarium*, the Contractive and Expanſive Forces of the Brain and the Heart appear to take their Origine, tho' the *Fœtus* afterwards receives in the Womb, by the means of the *Placenta*, an Acceſſion to the Latter of theſe Forces, from the Blood Veſſels of the Mother, albeit, others will not allow ſo much as that.

Why the Fœtus *comes into the World with it's Head foremoſt.*

THIS may however give an Account, why a *Fœtus* comes into the World with it's Head foremoſt, ſince the Brain being of a Contractive Nature Tends downwards, and the Expanſive Syſtem of the Blood upwards, when looſ'd from the Womb, ſuitable to all other Contractive and Expanſive Forces.

How the Mind is Proved to be Diſtinct from the Nervous and Sanguineous Syſtems, tho' United and Connected with them.

WE have hitherto only conſidered the Nervous and Sanguineous Syſtems in the Compages and Structure of an Human Body, in which we have made the Firſt to be of a Contractive Force, and the Laſt to be of an Expanſive; but as it is Evident, that the Nervous Syſtem has a Prodigious Force of Action and Expanſion Exerted by the Muſcles in a Quick, Lively, and Nimble Motion and Agitation of all the Limbs, we muſt ſuppoſe a Power Independent of, and Superior to, the Contractive Force of the foregoing Syſtem, which we call the Mind, and is the Spirit, which Actuates and Informs it.

Becauſe thoſe Syſtems, tho' they may Account for the Circulation of the Fluids, and the Conſiſtency of the Solids, they cannot Account for our Voluntary Actions.

THE Circulations of the Humours may be Performed in an Animal Syſtem from the Expanſive and Contractive Forces in them, but thoſe Expanſive and Contractive Forces cannot Account for the Free and Arbitrary Motions and Exertions of the whole Frame to one Part of Space or another, without any Previous Determination, unleſs from a Voluntary and Intelligent Agency, annext to the Syſtem it ſelf; But if we join a Spirituous or Expanſive Force from the Mind to the Contractive Force of the Nervous Syſtem, it may then have an Expanſion Superior even to that of the Blood; for thus Nitre, as all Salts, is of a Contractive Nature, and Wine of an Expanſive, and yet when Nitre is Exalted and Volatilized into a Spirit by Fire, and the Operations of Chymiſtry, it's Force is Mightier and Stronger than Alcohol, or the Fineſt rectify'd Spirit of Wine, which is Weak and Languid in the Compariſon.

Alſo becauſe if it Reſided as an Active Property in the Brain and Nerves, it would Exert it ſelf every where alike.

THAT the Mind, which Actuates the Nervous Syſtem, is Diſtinct from, tho' Joined and Connected with it, is manifeſt from hence, that if it Reſided, as an Active Property in the Brain and Nerves, it would Exert it ſelf always, and every where, in the Nervous Syſtem alike, and the Nervous Subſtance would be in it's own Nature Expanſive and not Contractive, as Spirit of Nitre is, and every Portion of that Subſtance would be Endued with the ſame Degree of Thought, Senſe, Perception, and a Freedom and Liberty of Action; On the Contrary, the Brain, and the Nervous Subſtance Derived from it, is in its own Nature Contractive, and is Expanſive only as the Mind Inſpirits and Envigorates it; nor does the Active Quality, Communicated to it by the Mind, Exert it ſelf alike in the Brain and Nerves, but Arbitrarily and at Pleaſure, ſometimes one Part or Member of the Body being moved by the Expanſive Force of them, and ſometimes another; neither yet is there the ſame Degree of Senſe, Thought, Perception, and a Freedom of Acting, in every Portion of the

Nervous Subſtance; For tho' we Feel and Perceive at our Fingers Ends, we do not Think there, and tho' all the Nervous Matter or Subſtance is furniſhed with Senſe, by which there is a Communication of it with the Mind, yet there is not the Mind, there is not the Reaſon, the Will, and Underſtanding in every Part of ſuch Nervous Subſtance, which reſides in the Brain only; which ſhews, that the Mind is not a Property of the Nervous Matter, but a diſtinct Being and Subſtance annext to it.

AGAIN, The Mind has both an Expanſive and a Contractive Force in the Properties and Affections of it, for it has Qualities belonging to it, as we have before ſhewn, which are directly Oppoſite and Contrary to each other; It has the Vertues of Sobriety, Humility, and Goodneſs, of Application and Study, Frugality and Prudence, and Wiſdom, which are Impreſſions upon it of a Cooler Temperament and Nature, and fall in with the Contractive Force of the Nervous Matter, or Subſtance; whilſt it is not Incapable of the Warmer and more Vicious Paſſions of Intemperance, Pride, Cruelty, Licentiouſneſs of Thought, Extravagance, Indiſcretion and Folly, which Ariſe from the Expanſive Force of the Sanguineous; Since therefore the Nervous and Sanguineous Syſtems are perfectly Repugnant and Oppoſite to each other, and cannot Conſiſt together in one, the Mind, which is capable of Receiving and Admitting the Impreſſions of Each, muſt be Different and Diſtinct from Both.

Likewiſe becauſe the Mind has an Expanſive and Contractive Force, which are Single and Divided in the aforeſaid Syſtems.

MOREOVER it is known, That Diſtempers, of a Contractive and of an Expanſive Nature, may both of them begin in the Mind by Paſſions raiſed there; Thus Grief, or Immenſe Study, or a Sudden and Panick Fear, may cauſe Melancholy and an Entire Depreſſion of the Contractive Force of the Nervous Syſtem; and Pride, an Intemperance of Paſſion, and a Vehement Emotion of the Mind, Madneſs and a Violent Fever in the Sanguineous; On the Contrary, if theſe Diſtempers have their Origin from the Animal Syſtem, the Firſt begins in the Nervous, and the Laſt in the Sanguineous; which ſeems to be a Demonſtration, that the Mind is a Subſtance Different from Both, and Adapted to Either, by it's Union and Conjunction with Them.

It admits of Diſtempers, which are Single and Divided in thoſe Syſtems.

LASTLY, The Mind, tho' Diſorder'd, continues Firm and Strong in it's Perceptions in both theſe Caſes, whilſt the ſeveral Syſtems of the Body are Impair'd and Weaken'd, and ſeems then only to Affect a Diſſolution from them, when it finds it's ſelf out of a Capacity, and unable any farther, to Govern the Irregular and Tumultuous State Introduced into Them.

The Mind is Strong, when thoſe Syſtems are Weakened.

THUS far we have ſpoke of the Membranes in General, and how they are Formed; And as to the uſes of them, there is nothing Alledged on that Head, which is not agreeable to the Account we have Given: We ſhall only therefore farther obſerve, that thoſe Membranes are the Thinneſt, which Encompaſs and Lie neareſt to the Contractive Forces in the Body, as the *Meninges*, or the *Pia* and *Dura Mater*, which Intercede betwixt the Scull and the Brain, the Coats of the Nerves, and the *Perioſteum* which Inveſts the Bones; and thoſe are Thickeſt, which Encompaſs or Lie neareſt to the Expanſive Forces in the Body, as the *Peritonæum*, the *Pleura*, the *Pericardium*, and the Coats of the Blood Veſſels; Becauſe the Contractive Force Tends Inwards, and therefore Diminiſhes the Thickneſs of the Former, but the Expanſive Force Dilates and Extends it ſelf Outwards, and by that means Swells and Increaſes the Thickneſs of the Latter; as alſo becauſe the Expanſive Force requires a Greater Contractive to Balance it, and a Contractive a Leſs.

Why the Membranes are the Thinneſt, which encloſe the Contractive, and the Thickeſt, which encloſe the Expanſive.

ALSO the Adipoſe Membrane is Thicker in the Neck, than in any other Part; ſince we have ſhewn, that the Air is Aſſiſting to the Forming of Fat in Conjunction with the Blood and the Nervous Subſtance, of all which there are Great Quantities; for there is not only the External Air, but that, which Paſſes thro' the *Pharynx* and *Larynx* into the Stomach and Lungs; there is likewiſe the *Medulla Spinalis*, and the ſeveral Cervical Nerves, which are Derived from thence in the Number of the Contractive Forces; and the Variety of Blood Veſſels Propagated from the Heart to the Head, which belong to the Expanſive; from which Quantities of the Contending Forces it is Rational to Think, there will be a Greater Portion of Fat Elaborated and Made.

Why the Adipoſe Membrane is Thickeſt in the Neck.

OF the Membranes, there is nothing therefore now Remaining for us to ſpeak to, excepting the *Membrana Carnoſa*, which lies above the *Membrana Communis Muſculorum*, or the *Muſculoſa*, and beneath the *Adipoſa*, and which is not to be found in Men,

Why the Membrana Carnoſa *is not in Men, but in Brutes.*

Men, and is obſervable in Brutes only; the Reaſon of which ſeems to be, that the Nervous Subſtance or the Contractive Force is more Powerful and Predominant in Men, and the Sanguineous or Expanſive in Brutes, by which, in the Former, the *Carnoſe Membrane* is Thinner and more Contracted, and in the Latter, more Dilated and Thicker; and upon the ſame Account, as the *Meninges* and *Perioſteum* are Thinner than the Coats of the Blood Veſſels, or the *Peritonæum*, *Pleura*, or *Pericardium*: From this Membrane and the Exceſs of the Expanſive Force ſeems to Ariſe that Great Protruſion of Hair obſervable in Brutes.

Why the Structure of the Animal Compages conſiſts of Fluids, and of Solids, which are Vaſcular.

LASTLY, This Theory of the Expanſive and Contractive Forces exactly Correſponds with what the Beſt and Lateſt Anatomiſts have Affirmed concerning the Compages and Structure of an Human Body, that it conſiſts Entirely of Fluids and Solids, the Laſt of which are ſaid to be Vaſcular; That is, however Solid any Part may Appear, it is yet Aſſerted, that it is nothing elſe than a Congeries of Hollow Tubes and Veſſels, containing ſome Liquors or other, which are Proper and Peculiar to them; For the Coats and Veſſels we have ſhewn are owing to the Contractive Force of the Nervous Syſtem, and poſſibly to the Internal Air of the Body, and the Humours of which they are the Conduits, to the Expanſive of the Blood and the Contractive of the Nervous Fluid, or to a Various Mixture of Them.

Concerning the Peritonæum *and* Omentum. Syllabus Enterologiæ. Dr. Gibſon's Anatomy, Chap. 4. & 5. Book 1. Dr. Keill's Chap. 2. §. 3. & 4. Dr. Drake's Anthropologia Nova, Chap. 6. & 8. Book 1. Blancard's Anatomia Reformata, Cap. 33. & 18.

§. 11. IN Diſſection, next under the *Membrana Adipoſa* and the *Membrana Communis Muſculorum* lie the Muſcles, of which there are Five Pair; the Outermoſt are the Obliquely Deſcending, the Next are the Obliquely Aſcending, the Third the *Recti*, the Fourth the Pyramidal, and the Inmoſt, the Tranſverſe; which being Removed, the *Peritonæum*, or the Inmoſt Coat of the Belly, called the Rim, Appears; It adheres above to the Midriff, below to the Share- and Flank- or Hip-Bones, in the Fore-Part firmly to the Tranſverſe Muſcles, but chiefly to their Tendons about the *Linea Alba*, behind to the Fleſhy Heads of theſe Muſcles looſely; It's Figure is Oval, and it's Subſtance Membranous, and it's Origin, according to *Fallopius* and Dr. *Gliſſon*, from the Superior and Inferior *Plexus* of Nerves of the *Abdomen*, for from them it cannot be Separated without Tearing; others Derive it from the Ligaments, by which the *Vertebræ* of the Loins and of the *Os Sacrum* are Knit one to another; It is Double every where, but appears to be ſo chiefly about the *Vertebræ* of the Loins, and in the *Hypogaſtrium*; For in the Former Place, between it's Membranes, lie the *Vena Cava*, the *Aorta*, the Receptacle of the Chyle and the Kidneys, and in the Latter the Bladder, and in Women the Womb.

IT has Three Perforations Above, where it adheres to the Diaphragm or Midriff; the Firſt on the Right-Side, for the Aſcending Trunk of the *Vena Cava*; the Second on the Left, for the Gullet to Deſcend by, with the Nerves of the Eighth Pair inſerted into the upper Orifice of the Stomach; and the Third, for the Deſcent of the *Aorta* and the Intercoſtal Nerve, and for the Aſcent of the *Ductus Chyliferus*; Below, It has Paſſages for the *Rectum*, for the Neck of the Bladder, and in Women for the *Vagina* of the Womb, Alſo for the Veins, Arteries, and Nerves, which Proceed down to the Thighs; Before, in a *Fœtus*, for the Umbilical Veſſels; It has likewiſe Two Proceſſes in Men, and Two in Women, which there is no occaſion here particularly to Deſcribe; If it breaks, it Cauſes a Rupture, either in the Groin or Navel: It has Arteries and Veins from the Mammary and Epigaſtrick, and from thoſe of the Midriff, and from the Phrenick, and has ſlender Threads of Nerves from the Pairs of the *Vertebræ* of the Loins, and it's uſe is to aſſiſt the Contraction of the Belly for the Expulſion of the Excrements, and to give an outer Coat to the Inteſtines.

UNDER the *Peritonæum*, in Diſſection, lies the *Epiploon*, *Omentum*, or Caul; It is compoſed of Two Membranes, betwixt which the Veſſels run, and the Fat and Glands are placed; They are very Thin, and, where the Fat hinders not, Tranſparent; It is compared by Dr. *Gliſſon* to a Woman's Apron, when the lower Part of it is Turned up, and Tuck'd under the Girdle; For it conſiſts of Two Leaves, whoſe upper Edges are Knit to Different Parts, but it's Bottom is Continued, and Reſembles a Pouch or a Satchel; The Fore-Leaf, beginning at the little Lobe of the Liver, which it Involves, Adheres to the Under or Hollow Side of the ſaid Liver, to the *Duodenum* or *Pylorus*, ſomewhat towards their Fore-Side, to the Bottom of the Stomach, and to the Suture of the Spleen; The Hinder or Inner Leaf is Continued from the Former, and, Paſſing from the Spleen backwards, Returns towards the Right-Side again, by the way

Adhereing to the *Pancreas*, to that Part of the *Colon*, which runs under the Stomach, to the Back, to the *Duodenum*, ſomewhat towards it's Back-Side, and at laſt is Joined or Continued to the Fore-Leaf at the aforeſaid little Lobe of the Liver; as for it's Bottom, it is knit to no Part, but hangs Looſe upon the Inteſtines, Reaching commonly a little below the Navel, and ſometimes to the very Bottom of the Belly; It alſo Cleaves to the *Peritonæum*, it aboundeth with Veſſels of ſeveral Sorts, which do not Terminate in it, but are carried thro' it to other Parts, namely, Arteries, Veins, and Nerves, which it is not Requiſite here particularly to Deſcribe; *Malpighius* thinks he has Diſcovered a fourth Sort, which he calls *Ductus Adipoſi*, but this is very uncertain, and there is nothing but Conjecture and Diſputed Obſervations for them; According to Dr. *Wharton*, in his *Adenographia*, there are Lacteal Veſſels paſs thro' it from the Stomach to the Common Receptacle of the Chyle; It has likewiſe Glands, which are ſaid to contain much Fat, and into one of which, that is joined to the *Pylorus*, the Lacteals are Inſerted; The Fat is unequally Spread over it, and is gathered chiefly there, where the Veſſels run, the Spaces betwixt being only Membranous; It is Collected in little Membranous Cells, Included betwixt the Two Inveſting Membranes, and it's Matter is Derived from the Blood Veſſels, according to the Common Opinion, but according to *Malpighius* from the *Ductus Adipoſi*; the Fore-Leaf has more Fat than the Hinder, and the upper Part of the Fore-Leaf, that is knit to the Stomach, is the Fatteſt of it: In very Fat Perſons, this Part grows to a Great Bulk, but in Conſumptive, there is little left beſides the Membranes and Veſſels; And *Peyerus* ſays, that in all Hydropick Perſons, that he ever Diſſected, the Caul was always Extenuated and Putrid.

The Uſes of it are, To Cheriſh the Heat of the lower Part of the Stomach, and the Inteſtines; To Miniſter Nouriſhment to the Parts, in a long Want of Food, it's Fat being received into the Veins, and mixt with the Blood; To convey Veſſels ſafely to other Parts; To keep the Inteſtines Moiſt and Glib; And to knit looſely together, the Stomach, Liver, Spleen, *Pancreas*, *Colon*, and *Duodenum*.

Thus alſo the *Syllabus* divides the *Peritonæum* into the *Lamina Exterior* and *Interior*, the *Proceſſus*, from whence is derived the *Tunica Elythroides*, or the *Vaginalis Teſtium*, and the Umbilical Veſſels, that is, the Veins, Arteries, and *Urachus*, And the *Omentum* into the *Ala Superior* and *Inferior*, the *Burſa*, the *Lamellæ*, the *Adeps in Cellulis*, and the Veſſels, namely, the Arteries, Veins, and Nerves.

§. 12. This is the Account, which the Anatomiſts give of the *Peritonæum* and *Omentum*; We have therefore, in Philoſophy, ſcarcely any Reaſon to add more, than what has been ſaid concerning the Fat and the Membranes; however we ſhall go on to ſhew, how theſe Phænomenons of an Human Body Conſiſt and Agree with our Doctrine of the Expanſive and Contractive Forces.

The ſeveral Phænomenons ſolved Relating to Them.

The Muſcles lie under the Adipoſe Membrane, and are entirely Formed, as to the Subſtance of Them, of Nervous Fibres and an Heap of Capillary and Infinitely ſmall Blood Veſſels; For the External Air, being now hinder'd by the Fat, and it's Membrane, from Proceeding any farther into the Human Frame, the Syſtems of the Expanſive and Contractive Forces of the Sanguineous and Nervous Matter are at full Liberty to Exert themſelves againſt each other; and by that Means are Spread and Diffuſed into a Thouſand Streams and Rivulets of Blood on the one Hand, whilſt the Nervous and Contractive Matter on the other Surrounds and Inveſts them with Coats, againſt which the Expanſive Force of the Blood Acting ſhapes them into Round and Hollow Canals, and the Contractive Force of the Nervous Matter Repelling ſuch Expanſion, the Blood becomes Progreſſive, and the Canals Tubular; whilſt in the mean Time the Nervous Matter is likewiſe carried in Oppoſition to the Sanguineous into Innumerable Filaments and Threads, which have alſo a Force and Power of Contraction.

How the Muſcles, lying over the Peritonæum, *are Formed.*

How the Blood Veſſels are Produced and why Tubular.

And from hence is derived the True and Natural Action of a Muſcle, which is the ſame, as that of the Heart, or any Artery, namely, that of a Syſtole and a Diaſtole, or of a Contraction and Dilatation; the Firſt Ariſing from the Cold or Contractive Force of the Nervous Matter, and the Laſt from the Hot or Expanſive of the Sanguineous; and it is a wrong Opinion of Anatomiſts, to Imagine, that the Proper Action of a Muſcle is Contraction only, ſince Dilatation is as Peculiar and Eſſential to it;

The Action of the Muſcles, whence derived, and what.

the One Proceeding from the Real Contractive Force of the Fibres of the Muſcle and the Coats of the little Blood-Veſſels, that is, from the Contractive of the Solids, and the Other from the Expanſive of the Blood, and the Fluids.

Why we are more Lively and Brisk in Cold Weather, than in Hot.

THIS Theory of the Muſcles again, ſuitable to what we have ſaid before, gives us a Reaſon, why Cold and Froſty Weather makes us more Active and Lively, as alſo Cold Bathing; when Hot and Sultry Weather, or the Warmth of a Fire, or the uſe of Spirituous Liquors, Renders us more Faint, Languid, and Unactive; Becauſe the Firſt Strengthens and Corroborates the Contractive Force of the Nervous Syſtem, and the Laſt Weakens and Diſſolves it.

How the Peritonæum *is Cauſed.*

UNDER the Muſcles, when Removed, the *Peritonæum* is Diſcovered, which, being a Membrane, does chiefly conſiſt of a Contractive Force, and is Evident from the Origin, which Anatomiſts aſcribe to it, that is, the Superior and Inferior *Plexus* of Nerves of the *Abdomen*, and the Ligaments, by which the *Vertebræ* of the Loins, and of the *Os Sacrum* are Knit one to another; by it's Adhereing to the Midriff, and to the Share- and Hip-Bones, and to the Tendons of the Tranſverſe Muſcles, which are all of a Cold, Solid, and a Contractive Nature; and by it's Looſe Adheſion to the Fleſhy Heads of the ſame Muſcles, which are of a more Sanguineous and Expanſive one; The Action alſo is from hence Contractive, by which it is aſſiſting to the Periſtaltick Motion of the Inteſtines, and to the Expulſion of the Excrements from Them: The Contractive Force of the Internal Air, it is Probable, obtains ſome Effect in the Conſtitution and Conſolidation of this Membrane, but being leſs Contractive than the External Air, and the Expanſive Force of Heat from the Blood being Greater, and the Contractive Force of the Nervous Syſtem being ſpread thro' it, It is of a Tenderer Nature than the *Cuticula*, or outward Skin, as well as of a more Senſible.

Why it is Double about the Vertebræ *of the Loins more eſpecially.*

IT is Double, eſpecially about the *Vertebræ* of the Loins, and the *Hypogaſtrium*, from a neceſſary Diviſion of it by Superior Forces; in the Former Place, by the Expanſive Force of the Blood in the *Aorta*, and the *Vena Cava*, and of the Chyle, in the Receptacle of it, by the Blood alſo in the Emulgent Arteries, and the Expulſion of the Serum by the Kidneys; and in the Latter, by the Deſcent of the Serum into the Bladder, and ſo to it's Excretion from the Human Syſtem.

The Reaſon of it's Perforations.

IT's Perforations are owing to the ſame Cauſe of Superior Forces, the Expanſive Force of the Blood in the *Aorta* and *Vena Cava*, of the Protruſion of Meat thro' the Gullet, and of the Chyle thro' the *Ductus Chyliferus*, of the Expulſion of Excrement thro' the *Rectum*, of the Blood which paſſes down thro' the Arteries to the Thighs, and up thro' the Veins from thence, the Nerves by it's Oppoſite and Contractive Force continually Attending them, and laſtly, of the Blood in the Umbilical Veſſels; And by a Superior Force, Ruptures are Cauſed, or an Enlargement of certain Perforations: It gives an outer Coat to the Inteſtines from a Diffuſion of it's Contractive Force, by which thoſe Coats likewiſe obtain their Periſtaltick Motion, as will be ſhewn afterwards.

The Phænomenons of the Omentum *Explained.*

THE *Epiploon, Omentum*, or Caul, lies next under the *Peritonæum*, and immediately covers the Inteſtines, which conſiſts of Fat and a Membrane, the Laſt of which is derived from a Diffuſion or Extenſion of the Coats of the Numerous Veſſels, which Paſs thro' it, which makes it ſo Exceeding Thin, and from the Coats of the Entrails to which it Adheres; The Firſt ſeems to be made, as before, from a Mixture of the Expanſive Force of the Blood, and of the Contractive of the Nervous Matter, and of the Internal Air, which is the Reaſon, that it is chiefly gathered there, where the Veſſels Run, and is found in the Greateſt Plenty in the upper Part of the Fore-Leaf, where it is Joined to the Stomach, which Abounds with Veſſels of it's own, and is Repleniſh'd with Air, which Enters with the Aliment; There is little of it in Conſumptive Perſons, becauſe the Expanſive Force of the Blood, and the Contractive of the Nervous Matter, is too much Weakened and Impair'd to be capable of Producing it; and it is Groſſer, and leſs Oily and Fluid, than the Fat of the Adipoſe Membrane, upon the Account of the Internal Air being more flat and leſs Spirituous and Springy than the External, and of the Contractive Force of the Nervous Matter being Greater; from which firſt Cauſe it is, that there are fewer Veſicles or Bladders in This, than in That.

CHAP. IV.

Concerning the Oeſophagus *or Gullet, the* Ventricle *or Stomach, the* Inteſtines *or Guts; and of the Mouth and Palate.*

§. 1. AFTER the *Abdomen* is laid open, and the *Omentum* is taken off, the Inteſtines appear, which being continued to the Stomach, and That to the Gullet, it will be neceſſary to Diſcourſe of Them together.

An Account of the Gullet, Stomach, Guts, and of the Mouth and Palate, by Anatomiſts. Syllabus Enterologiæ. Prælect. 2. Dr. Gibſon's Anatomy, Chap. 6, 7, 8. Book 1. Dr. Keill's Anatomy, § 5, 6, 7. Chap. 2. Dr. Drake's Anthropologia Nova, Chap. 9, 10, 11. Book 1. Blancard's Anatomia Reformata, Cap. 19, 20, 21. Tauvry's Rational Anatomy, Chap. 1, 2, 3. Part 1.

The Gullet.

THE *Oeſophagus, Stomachus, Gula,* or Gullet, begins at the Root of the Tongue behind the *Larynx,* which Part of it is called the *Pharynx,* and Deſcends from thence between the Wind-pipe and the *Vertebræ* of the Neck, and the Four Firſt *Vertebræ* of the *Thorax,* in a Direct Line; at the Fifth *Vertebra* it bends a little to the Right-ſide, by giving way to the Deſcending Trunk of the Great Artery, which it Accompanies to the Ninth *Vertebra,* and then Turns a little to the Left and Climbs upon the Artery, and about the Eleventh *Vertebra* Paſſes thro' the Midriff a little on the Left-ſide of it's Nervous Centre, at a Hole Diſtinct from the Great Artery, and is Inſerted or Continued unto the Left Orifice of the *Ventricle* or Stomach, which is Situate immediately under the Midriff; in the Fore-part on the Right-ſide it is Covered with the Hollow-ſide of the Liver, on the Left-ſide it is Touched by the Spleen; it's Back-ſide upon full Feeding bears againſt the *Vena Cava* and *Spine,* and to it's Bottom Length-ways is the Caul knit; the Back-ſide of it's Bottom reſteth on the *Pancreas,* and the Fore-ſide on the *Colon,* all which promote it's Heat; It is Longiſh and Pretty Round, very much Reſembling a Bag-pipe in Shape; It hangs Croſs the Body, and it's Two Orifices, by which the Meat is Received in from the Gullet, and let out into the Guts, ſtand higher up than it's Middle, ſo that it's upper Part makes, as it were, the Concave of an Half-Moon. The *Cardia,* or Left Orifice, hath Orbicular Fibres, that it might be exactly ſhut leſt Fumes, and the Heat, ſhould break out to the Hindrance of Concoction, and Annoyance of the Head. The *Pylorus* has it's Inmoſt and Nervous Coat full of Wrinkles, and it's Middle or Carnous has Two Ranks of Fibres, Annular or Tranſverſe, to ſtreighten or ſhut up this Paſſage upon Occaſion, and ſuch as run Length-ways, which draw the reſt of the Stomach towards this Door, for the Diſtribution of the Chyle into the *Duodenum;* but if they draw the Contrary way, Vomiting is Produced, and the Choler and Pancreatick Juice ſometimes pumpt into the Stomach.

The Stomach.

THE *Ventricle,* or Stomach, is more Capacious on the Left-ſide than on the Right; It's Left or Upper Orifice is Continued from the Gullet, by means whereof it is knit to the Midriff; and it's Right or Lower Orifice is Continued to the *Duodenum;* It's Bottom, in the whole Length of it, has the upper Edge of the Fore-Leaf of the Caul adhereing to it, by whoſe Mediation it is joined to the Liver, Back, Spleen, *Colon* and *Pancreas;* the Upper Orifice is called *Cardia,* and the Lower is termed *Pylorus.*

The Guts.

THE *Inteſtines* or Guts are Continued from the *Pylorus* to the *Anus,* and are knit together by the *Meſentery,* by which, and by the Intervention of the *Omentum,* part of which Adheres to the Beginning of the *Duodenum* and the Middle Part of the *Colon,* they are tied to the Back, and fill the Greater Part of the Cavity of the *Abdomen;* and the Length of them is about Six Times the Perſon's Length, whoſe they are; They have a Periſtaltick, Vermicular, or Worm-like Motion, which begins at the Left Orifice of the Stomach, and is Promoted quite thro' them.

THEY are Divided into Two Sorts, the Thin or the Small, and the Thick or the Large; the Firſt are placed Above, are Long, Equal, Round, Rolled about in Wreaths, Full of Wrinkles, Interwoven with Innumerable Veins, and Chyle is found in them; On the Contrary, the Thick are placed Below, are Short, Anfractuous, without Twiſting Wreaths, Endued with Fewer Veins, and the Wrinkles or Folds in the Guts are Expanded, and there Reſult from them certain Receſſes or Cells, and the *Fæces* are found in them; The Thin poſſeſs the Umbilical *Region* and *Hypogaſtrium,* and are diſtinguiſhed into the *Duodenum, Jejunum,* and *Ileon;* The Thick are the *Cæcum, Colon,* and *Rectum,* at the Extremity of which is placed the *Sphincter.*

The Duodenum. THE *Duodenum* is ſo called, from being ſuppoſed by the Antients to be about Twelve Inches Long, which in Sheep is ſo, but in Men not above Four Fingers; It reaches to the *Pancreas*, and is not knit to the *Meſentery* but the *Omentum*; It is Thicker in it's Membranes, than the *Jejunum* and *Ileum*, but it's Paſſage ſtraiter; Towards it's Lower End it has commonly Two Ducts Leading into it, the *Ductus Choledochus Communis*, by which the Bile enters this Gut from the Liver, and a little below the *Ductus Pancreaticus*, by which the Pancreatick Juice is convey'd into it from the *Pancreas* or Sweet-Bread; tho' ſometimes theſe Two Ducts are joined into one, and open by one Mouth into this Inteſtine.

The Jejunum. THE *Jejunum* is ſo called, becauſe it is for the moſt Part empty, both upon the Account of the Multitude of Lacteals, which are Inſerted into it, by which the Chyle is carried off from it, and of the Fermentation of the Acrimonious Choler with the Pancreatick Juice, which are brought into the Inteſtines juſt before it's Beginning; It is about Eight Feet in Length, and begins on the Right-ſide, under the *Colon*, where the *Duodenum* Ends, and the Guts begin to be Wreathed, and is Continued to the *Ileum*; From which it is Diſtinguiſhed by it's Emptineſs, and by it's Greater Number of Veins and Arteries, from which it looks Reddiſh; as alſo by the nearneſs of the Folds or Wrinkles of it's Inmoſt Coat one to another, which are but about half an Inch Diſtant, whereas in the *Ileum* they are a whole Inch, or more; and laſtly, by it's Coats, which are Thicker than thoſe of the *Ileum*.

The Ileum. THE *Ileum*, ἀπὸ τȣ̃ εἰλεῖσθαι, is ſo called from it's many Turnings and Windings, is in Length about Twenty Feet, and is the Narroweſt of all, being about a Finger's Breadth in Diameter; It is Diſtinguiſhed from the *Cæcum* or *Colon*, which make one continued or ſtrait Canal, the Lower-ſide of which the *Ileon* aſcending Pierces, and Enters Tranſverſely to it, and into the Latter whereof it's Inner Coat hangs looſely the Length of half an Inch, Forming the Valve it ſelf of the *Colon*, and is the Limit, that divides the *Cæcum* from it: When this Inteſtine falls into the *Scrotum* it Cauſes a Rupture, and when there is a Contortion of it, or an Obſtruction in it, or an Intruſion of one Part into another, the Iliack Paſſion, in which the Excrement is voided by the Mouth.

The Valvulæ Conniventes. THE Wrinkles in the Inſide of theſe Inteſtines are, what the Modern Anatomiſts Term the *Valvulæ Conniventes*, which are made from the Inmoſt Coats being longer than the Two other, and which therefore ſtreighten the Paſſage, and detain the Chyle, that the Lacteals may have more Time to Imbibe it; Theſe Wrinkles are neceſſary, that the Inmoſt Coat may comply with the Outward and Muſcular, upon it's Diſtention and Dilatation, which, when Contracted, Determines it into theſe *Plicæ* or Folds, the Inner Coat being, like the Outward Skin or *Cuticula*, without any Senſe or Motion in it ſelf, as having neither Nervous nor Fleſhy Fibres.

The Cæcum. OF the Thick Guts the *Cæcum* is the Firſt, being only a Continuation of the *Colon*, and is called the *Blind*, becauſe one End of it is Cloſed, and the other is Joined with the Cavity of the *Colon* by a large Mouth, which opens into it, tho' in Men it is only about as Thick, and half as Long, as a Larger Earth-Worm ſtretched out at Length; It is Bigger in Infants than in Men, and in a *Fœtus* is a Repoſitory for the *Fæces*, and in Sound Perſons is generally Empty; In Four-footed Beaſts it is always full of Excrements, in Apes it is Larger than in Men, in Dogs than in Apes, and in Conies, Squirels, and Rats, Largeſt of all, in Proportion to their Bodies.

The Colon. THE *Colon*, ſo called from κῶλον or κοῖλον, becauſe it is the Holloweſt and Wideſt, or ἀπὸ τȣ̃ κωλύειν, from Detaining the Excrements, begins at the *Os Ilium* on the Right-ſide, and Aſcending by it's *Spine*, Arrives at the Right Kidney, to which Parts it is joined by a Membranous Connexion; From thence bending Left-ways it Creeps under the Liver, by the Gall-Bladder, to the Bottom of the Stomach, to the whole Length of which it is tied by the Mediation of the Fore-Leaf of the Caul, as it is to the *Pancreas* and Loins by the Mediation of the Hinder-Leaf; Then it comes to the Lower Part of the Spleen, to which it is likewiſe Joined, and afterwards Touching and firmly Adhereing to the Left Kidney by Fibres, it comes to the Left *Os Ilium*, from which Deſcending by the Left Groin to the *Pelvis*, it embraceth the Bottom of the Bladder behind on each Side; Then it Aſcends upwards by the Right Groin near the Place, from whence it Firſt took it's Riſe, and thence Marching back again towards the Left-ſide, and Running it ſelf in betwixt the *Ileum* and the Back-Bone, it Reaches to the Top of the *Os Sacrum*, and there Unloads it ſelf into the *Rectum*; It is about Seven Feet Long, and goes almoſt quite Round the *Abdomen*, next to the Muſcles, that it may better be Compreſſed by Them for Avoidance of the Excrements; It is Furrowed on the Outſide, and Ridged in the Inner, by which it becomes Divided into Cells, which Proceeds from the Inmoſt Coat Exceeding the Outward in Length, but chiefly from the Ligament, which is half an Inch Broad, that Runneth on the Upper and Middle Part of this Gut, and is much ſhorter than the Membranes of it; Theſe Cells hinder the Excrements from flowing into one Place, which would Compreſs the Parts Adjacent, and keep the *Fæces* from Deſcending too haſtily, that we may not have a continual Need of going to Stool; On it's Outſide, eſpecially from it's Paſſing by the Spleen to it's Joining to the *Rectum*, it has a Great many Fatty Knots, which ſerve to Moiſten and Lubricate it, that the *Fæces* may Paſs more eaſily; The *Rectum* has the like for the ſame Reaſon: The *Valve*, which, as before Expreſſed, is the Inmoſt Coat of the *Ileum* Propending or Hanging out Flaggy into the *Colon*, Cauſes that Flatuoſities cannot Aſcend from this Latter into the Former, much leſs Excrements Regurgitate; but if the Periſtaltick Motion be Inverted, as in the Iliack Paſſion, ſo that the Inmoſt Coat of the *Ileum* be drawn back from it's Depending into the *Colon*, the Excrements of the *Colon*, and Clyſters themſelves, may Aſcend up thro' the Small Guts into the Stomach, and be thrown up by Vomit.

The Rectum. THE *Inteſtinum Rectum*, or Strait Gut, begins at the Firſt *Vertebra* of the *Os Sacrum*, where the *Colon* Ends, and Paſſes directly Downwards to the Extremity of the *Coccyx*; 'Tis faſt tied, on it's Back-ſide, to both theſe Bones, by Mediation of the *Peritonæum*, to keep it from Falling out; and on it's Fore-ſide in Men it grows to the Neck of the Bladder, from whence, in the Pain of the Stone there, a *Teneſmus* or a Continual Inclination to go to Stool happens, but there is a Muſculous Subſtance comes between; It is a Foot in Length, not ſo Wide as the *Colon*, but it's Membranes Thicker.

The Sphincter. THE *Sphincter* Muſcle is placed at the very Extremity of the *Rectum*, by which it is cloſe Purſed up to hinder the Continual Exit of the *Fæces*, and is Forced open by a Voluntary Relaxation, and the Compreſſion of the Guts, and their Contents, by the Contraction of the *Abdominal* Muſcles; by too much Straining, or by Aloetick Purges, the *Rectum* ſometimes is ſo far Protruded, as to require an Artificial putting up again.

Three Tunicks. THIS is a ſhort Account from Anatomiſts of the Inteſtinal Paſſage from the *Pharynx* to the *Anus*, as to the Windings, Turnings, and the Various Situation of it; The next Thing to be Deſcribed is the Subſtance and Contexture of it; And in this all the ſeveral Parts of it Agree, *viz.* in being Compoſed of Three Tunicks or Coats, the Common, the Muſcular, and the Nervous or Tendinous, which laſt conſiſts of Blood-Veſſels, Little-Glands, and a Cruſt or a kind of *Cuticula*, with a ſort of Down or Velvet upon it; beſides which, the Stomach and Inteſtines, in General, have their Blood-Veſſels, their Nerves, and their Secretory Ducts.

The Common. THE outmoſt Tunick, or the Common, is very Thin, being only Endued with Membranous Fibres, and thoſe very Slender, and in the Gullet is ſuppoſed to be Derived from the Midriff, or the *Pleura*, or the *Peritonæum*, or from the Ligaments of the *Vertebræ* of the Neck and Breaſt, upon which it Reſteth, or from all of them: In the Stomach, it's Fibres, being Nervous, are Strait, Running from one Orifice to the other, and Encompaſſing both it's Bottom and Sides in their whole Longitude, and they Croſs, at Right Angles, the Carnous ones lying next under: In the Inteſtines it is of the ſame Fibrous and Membranous Texture, and is Derived mediately from the *Peritonæum*, but immediately from the Membranes of the *Omentum*, and of the *Meſentery*.

The Muſcular. THE Second Tunick, which lies under the Former, is the Carnous or Muſcular, which, In the Gullet, conſiſts of Two Ranks of Fleſhy Fibres, which Aſcend and Deſcend obliquely, Spiral-wiſe, and do mutually Intercuſſate, or Croſs, one another, ſo as that the Fibre, which, before it met with another to Interſect, did lie underneath another, Rides upon that which it Interſects, and ſo continues uppermoſt, till it comes to a Second, under which it Paſſes again, and ſo on by Turns: In the Stomach,

mach, it alſo Conſiſts of Two Ranks of Fleſhy Fibres; the Outer of which are the more Numerous, and are Tranſverſe, Running Croſs, or Round, the Stomach; the Inner go ſtrait from the Left Orifice to the Right on the Top of the Stomach, and the Remainder of Them tend along each Side of it, obliquely forwards toward the Bottom, and meet one another there: In the Inteſtines, it likewiſe conſiſts of Two Ranks of Fleſhy and Moving Fibres, the Outer is of ſtrait ones, which reach along the whole Length of the Inteſtines, and cut the Circular ones under them at Right Angles, and their Tendon ſeems to be the outmoſt Coat, which being wholly Nervous, or as it were Tendinous, is wrapt about the whole Rank of theſe Fibres; the Inner is Annular or Tranſverſe, or, as others, Spiral, which, Encompaſſing the whole Cavity of all the Inteſtines in very cloſe Order, is Inſerted into the Hem or Selvedge of the *Meſentery*, as into it's Tendon.

The Nervous. THE Third Tunick or Inmoſt is Nervous, Lined with a Velvet or Downy Subſtance, and, In the Gullet, the Fibres are ſtrait, according to the Ancients, but according to Dr. *Willis*, they are variouſly Interwoven one with another, it is continued to the Membrane, which covers the Mouth, Jaws, and Lips, and Deſcends Three Fingers Breadth below the Mouth of the Stomach, from whence Proceeds that Great Conſent among theſe Parts in Vomiting: In the Stomach, it is the ſame, Nervous, Lined with a Downy Cruſt, and it is Endued with all Sorts of Fibres, but the ſtrait are the moſt Numerous; It is beſet with abundance of Small Ring-like Glands, which appear, when the Down is taken off, which is called the Glandulous Coat, and which when Removed, the Nervous one is Diſcovered, along which Abundance of Arteries and Blood-Veſſels Run, that Terminate in it's Inner Superficies, which Adheres to the Glandulous Coat; There is alſo a *Parenchyma*, which ſome think wholly Glandulous, which is Diſperſed, eſpecially in it's Middle or Muſcular Coat, and is not Sanguineous, but of a Slimy Nature; it fills the Inequalities, which ariſe from the Texture of the Fibres, and is ſcraped off from the ſmall Guts in Great Plenty, by thoſe, who make Strings for Muſical Inſtruments; and it is Evident, the Subſtance of the Stomach and Guts is the ſame: In the Inteſtines, the Downy Coat ſerves as a Filtre for the Chyle, before it Enters into the *Vena Lactea*, and hinders Excoriation from ſharp Humours.

Blood-Veſſels, and Nerves. ALL theſe, The Gullet, Stomach, and Inteſtines, have Arteries, Veins, and Nerves, Communicated to them from the Adjacent Parts, and which are Spread and Diſperſed thro' their whole Subſtance.

Glands. THERE are alſo the Glandules, called the *Tonſillæ* or Almonds, which lie in the Throat, at the Root of the Tongue, next to the Gullet, and Two more on the Backſide of it, which have their Arteries, Veins, and Nerves, likewiſe belonging to them; The *Tonſillæ* are ſaid to be of a Yellowiſh Colour, and their Subſtance to be like Concreted Honey, only of a firmer Conſiſtence; They have a Large Duct or *Sinus*, which opens into the Mouth, and Diſcharges into it the Liquor Separated in Them.

IN the Inmoſt Coat of the Inteſtines, Anatomiſts, and *Peyerus* in Particular, have Obſerved abundance of Glands, beſides thoſe, which Form the Glandulous Coat of Dr. *Willis*; They appear like little Teats with a ſmall Pore at the Top towards the Cavity of the Gut, and their Baſes, or Back-ſides, have Blood-Veſſels and Nerves Inſerted into them, and there Iſſues out of the Pore a Clammiſh Humour; There are few of them in the *Duodenum* or *Jejunum*, and they are the moſt Numerous in the *Ileum*.

Actions. THE Two Chief Things obſervable in theſe Parts, are the Chylification of the Stomach, and the Periſtaltick Motion of the Inteſtines. This is a ſuccinct Account of the Inteſtinal Paſſage, as to the Situation, Subſtance, and Action of it; but ſince we are to Diſcourſe of Digeſtion, and the Chyle, before we leave this Subject, it will be Requiſite to ſubjoin here a Deſcription of the Palate and Mouth, to which the ſaid Inteſtinal Paſſage is continued, and which conſiſts of ſeveral Parts.

Concerning the Mouth and it's Parts. THE Teeth and Gums we omit, as commonly known.

The Palate. THE Palate, or Roof, of the Mouth is Concave like a Vault, and Formed in the *Os Sphenoides*, which is covered with a peculiar Glandulous Fleſh, and a Thick Tunicle full of little Holes for the *Saliva*, which is ſeparated by the Glands, to Paſs thro' into the Mouth; There are ſaid to Spring out of it Innumerable ſlender Ducts, which Perforating the Membrane make it like a Sieve.

The Uvula.

THE *Uvula* is a Red, Spongy, and Longiſh *Caruncle*, which, being ſomewhat Broad at it's Baſis, hangs down from the Middle of the Palate, where the Noſtrils open into the Mouth, with a Small but Bluntiſh End.

The Tongue.

THE Tongue has Two Membranes, The Outer, which covers the upper Part only, and is pretty Smooth in Men, but Rough in Brutes with Cartilaginous Prickles riſing out of it, and ſtanding, like the Teeth of Wool-Cards, towards the Root of the Tongue; The Inner covers the whole Tongue, is Thin and Soft, and has many *Papillæ* Protuberating out of it, which in the upper Part Intrude themſelves into the Pores of the Outer; this Inner *Malpighius* calls a Nervous and Papillar Body: The Subſtance of the Tongue is ſaid by ſome to be That of a Gland, by Others to be Peculiar to it ſelf, and by Dr. *Wharton*, *Spigelius*, and *Malpighius*, to be That of a True and Real Muſcle; the Laſt of whom Informs us, that immediately under the aforeſaid Membranes, there lie ſtrait Fleſhy Muſcular Fibres, whereby the Tongue is drawn Inwards, and Shortened, but that the Center of the Tongue conſiſts of a manifold Kind of Fibres, Long, Tranſverſe, and Oblique, which, Riding one upon another, are Interwoven like a Mat; and yet Dr. *Gibſon* thinks it cannot be Properly called a Muſcle, becauſe no Muſcle ſerves to Move it ſelf, but ſome other Part, and becauſe one Muſcle is not Moved by another, as the Tongue is by ſeveral Pair; It is Connected to the *Os Hyoides*, *Larynx*, and *Fauces*, and by a Membranous Ligament to the Parts under it; It has it's Veins, Arteries, and Nerves, derived into it from the Adjacent Places.

Glands, The Parotides.

BESIDES the Glands above-mentioned, there are the *Parotides*, the Conglobate, and Conglomerate, which are both Seated in the Hollow under the Ear, and were formerly Reputed Emunctories of the Brain; but now the Conglobate are ſuppoſed to ſeparate the *Lympha* from the Arterial Blood, and convey it by Lympheducts into the Jugular Veins; the Conglomerate have not only Inſerted into them Veins, Arteries, and Nerves, but there alſo Springs out of each a Salival Duct by many ſmall Roots, which Running along opens into the Cavity of the Mouth, into which it Diſcharges the *Saliva*, which it Receives from the *Parotis* of it's own Side, and is called *Ductus Salivalis Stenonianus* from it's Inventor *Steno*.

Nuckianæ.

THE Second Glands, called *Nuckianæ* from Dr. *Anthony Nuck* a Dutch-Man, are ſeated in the Orbit of the Skull, wherein the Eye is placed, their Figure is Various in Different Perſons, Oblong, Oval, or Triangular, they have Arteries, Veins, and Nerves Inſerted into them; Each has a Salival Duct, which Deſcending downwards comes to the upper Part of the Gum in the upper Jaw, near to the Second Double Tooth, Reckoning from behind forwards, where it Empties it ſelf very near that of *Steno*'s.

The Maxillar.

THE Third Glands are the *Maxillar*, which are External or Internal; The External are ſmall and of little Moment, they are ſeated outwardly about the Middle of the Lower Jaw, where an Artery, a Vein, and a Nerve, Aſcend into the Muſcles of the Face, they ſeparate a *Lympha*, and Convey it into the Neighbouring Jugular Veins; The Internal are ſeated immediately within the Lower Jaw, their Hinder-ſide is next to the *Parotides* and Jugular Glands, and is Thicker, Rounder, and Redder; They grow Thinner by Degrees, and are Extended betwixt the Jaw and the Muſcles of the Tongue, as far forward as to the Chin; They are Conglomerate, and have each a proper Salival Duct belonging to them, which Spring by many Roots out of the Thicker and Hinder Part of the Glands, and run ſtrait forwards to the Middle of the Chin, where they End juſt within the Gums, and have a certain *Papilla* affixt to their Orifice, whereby they can eaſily Diſcharge themſelves, and yet nothing Return out of the Mouth into them.

The Sublingual.

THE Laſt Glands are the *Sublingual*; They lie underneath the Tongue on each Side, and each of them ſends forth a Salival Duct, which, Running Parallel with thoſe of the Internal Maxillar Glands, open in the ſame *Papillæ*, but have a peculiar Orifice of their own, ſtraiter than that of the other.

THE uſe of all theſe Glands is to ſeparate the *Saliva*, and to convey it into the Mouth by the Salival Ducts; the Origin of the *Saliva* is ſaid to be moſt Probably derived from the Arterial Blood, the Serous Part of which, the Gland beſtowing a ſubacid Quality upon it, is made into Spittle, to the Compoſition whereof ſome think a Nervous Juice is Contributed, becauſe Larger and more Numerous Twiggs of Nerves are Communicated to the Glands, than to moſt other Parts, which yet have a more Exquiſite Senſe than theſe; againſt which Dr. *Nuck* alledges, that if the Nerve, that Runs to any Gland be either hard tied or cut in Sunder, the Secretion of the *Saliva* will not thereupon Ceaſe, but only will proceed more Slowly; The *Saliva* is eſteemed to be a Ferment, and by ſome to be an Univerſal one for Meats and Drinks, and it is Thought to have Acids, Volatile Salts, and Oleous Particles, in it.

How the Fœtus *is Formed in the Womb, by the Intervention of the Expanſive and Contractive Forces.*

How the Mouth is Formed.

§. 2. To Account in Philoſophy and Nature for the Cavity of the Mouth and the Inteſtinal Paſſage, we muſt ſuppoſe, that in a *Fœtus* in the Womb, which has a Brain, or a Nervous Subſtance chiefly from the *Semen*, or a Nervous Juice, Imparted by the Male Parent, and a Heart or a Red Beating Speck from the *Ovum* of the Female, as before Explained, which Acting againſt each other by their Contractive and Expanſive Forces, and Exciteing the Animal Motion in the Syſtem, that is a-Forming, Produces by Degrees that Syſtem, we muſt I ſay neceſſarily ſuppoſe, that there muſt be an Aliment to ſupport, and Mature the growing *Embryo*, which making it's way by it's Expanſive Force, opens a Paſſage to it ſelf, and is the occaſion of that *Foramen*, we call the Mouth; For there being now Two oppoſite Forces contending in the *Ovarium* the Contractive and Expanſive, and the Contractive being the ſtrongeſt, by which the *Ovum* is Impregnated and Actuated, and is brought down thro' the *Tubæ Fallopianæ* into the Womb, and the Human Syſtem endeavouring to Preſerve it's own Æquilibrium, the Expanſive Force of the Nutritious Juices in the Female Parent is Directed towards the Contractive, which is Derived into it from the Male, in order to Preſerve an Equal Balance betwixt them.

Why the Head and Brain in the Embryo, *is Larger in Proportion to the Reſt of the Parts of the Human Syſtem, and how the* Fœtus *is Expelled from the Womb.*

For which Reaſon the Head, and the Brain, in the *Embryo* is Exceeding Large in Proportion to the other Parts of the Body, that is, the Contractive Force is much Greater than the Expanſive; but the Expanſive Force of the Nutritious Juices of the Female Parent, being ſtill ſent in to Counterpoiſe the Contractive, the Body and it's ſeveral Members Increaſe, till the Contractive and Expanſive are *in Æquilibrio*, when the Infant is come to Maturity, and preſently after is by the Superior Expanſive Force of the ſaid Parent Expelled from the Womb.

Why the Mouth is in the Head, and at that Diſtance from the Fore head rather than in it.

From hence it is Manifeſt, why the Mouth is in the Head, and at that Diſtance from the Fore-head, rather than in it, becauſe the Contractive Force in the Brain is too Great to admit the Expanſive Force of the Nutritious Juices from the Mother, but yet the Expanſive Forces of thoſe Juices exert themſelves, as near to the Contractive, as Poſſible, in order to Balance and Oppoſe it.

How the Cavity of the Palate is Formed, and the Tongue.

The Nutritious Juices, Entering here, lie for ſome Time, and Expand themſelves againſt the Contractive of the Nervous, by which means the Cavity of the Mouth and Palate is Formed; and the *Os Sphenoides*, being the Boundary of theſe Forces, is Acted upon by both, and is beaten and hardened into a Cartilage, and from thence into a Bone: A way being now made for the Expanſive Force of the Nutritious Juice into the New Syſtem, there is a continual Acceſſion of it, by which the Former is protruded Downwards, and Forms the Tongue, which Acting againſt the Contractive, Adheres to the *Os Hyoides*, and afterwards by Reverberating againſt the Contractive Force of the Brain, and the Contractive Acting againſt it, gives it that Facility of Motion we Experience in it, and which is alſo the Reaſon, why the Under Jaw is Expanſive and Moveable, whilſt the Upper is Contractive and Quieſcent; The Nutritious Juices ſtill Continuing their Influx to Balance the Contractive Force of the Brain, Form the Fleſh of the Gums and Palate, which are ſtill oppoſed by the Contractive Forces of the Brain, from whence are Produced the Cartilages or Bones under them.

How the Nerves and Blood Veſſels betwixt the Heart and Brain are Formed.

And all theſe Nutritious Juices are ſtill Aſſiſtants, and come in, as Auxiliaries, to the Expanſive Force of the *Ovum*, and the Red-Beating Speck, the Heart, which is the Seat of the Expanſive, which in the mean Time Exerts it ſelf in Streams or Radius's againſt the Contractive of the Brain, whilſt that Oppoſes it, by ſending out Nerves and a Nervous Subſtance againſt it, by which the Nerves, and the Nervous Coats of the Blood-Veſſels betwixt the Heart and Brain are Formed, and the Blood is Incloſed and Reſtrained within them.

How the Inmoſt Coat of the Gullet, Stomach, and Inteſtines is Formed.

THE Aliment and the Expanſive Force of it Preſſing on, and not being able to Proceed upwards, by Reaſon of the Repulſion of the Contractive Force of the Brain, nor forwards, by Reaſon of the *Medulla Oblongata* and *Spinal* Marrow, which is a Dilatation and Extenſion of the Brain in order to Reſiſt the Expanſive Force from the Maternal Juices; and the Aliment alſo coming to the Aſſiſtance of the Heart, and it's Blood, and the Expanſive Force of them, Tends downwards, and Proceeds towards the Heart; The Contractive Force of the Brain and Nervous Subſtance at the ſame Time is not Idle, but Exerts it ſelf from the Brain, the above-mentioned *Medulla Oblongata*, and *Spinal* Marrow, againſt the ſaid Expanſive of the Aliment and Nutritious Juices, and by that Contraction Inveſts and Surrounds them with the Nervous Coat before Deſcribed, or the Inmoſt Coat of the Gullet, Stomach, and Inteſtines.

Concerning the Infant, when Born, and how the Down or Velvet is Induced upon the Innermoſt Coat of the Inteſtines.

§. 3. AFTERWARDS, when the Infant is Born, and Produced into the open Air, this Coat, being extremely Senſible and Tender, is the occaſion of thoſe frequent Pukeings and little Vomitings of Children, even upon Receiving only the Milk of the Mother into the Stomach, and of the Convulſions and Inquietudes ſo Common to them; but by Degrees from the Contractive Force of the Air, which Enters every Day with the Aliment, the *Cruſta* is Induced upon it, and a kind of Down or Velvet, from the Shootings out of the Nervous Subſtance of the Coat, which are hardened by the ſaid Contractive Force of the Air into Small Iceicles, which, together with the *Cruſta* thus Congealed and Condenſed by the Air, Form a kind of *Cuticula* to the Gullet, Stomach, and Inteſtines, which Defends the Nervous Coat from any Internal Injuries, as the Real *Cuticula* does the *Papillæ* of the Nerves of the *Cutis* from External ones; That the Air has ſuch a Contractive, and Congealing or Condenſing, Force is Evident, not only from it's Effects upon the *Cuticula*, but upon Bread, Clay, Mortar, Stone, and a Thouſand other Bodies, which it Reduces from Soft and Pulpous Subſtances into Hard and Conſiſtent ones, and even Fluid ones into Ice, where, as in Winter, the Contractive Force is Increas'd by an Abſence of the Sun's Expanſive, and the Greater Influence of the Moon's Contractive.

That the Moon has a Cold or Contractive Force, and is of a Globular Figure, Demonſtrated from a Total Eclipſe of the Sun.

WE ſuppoſe here the Moon to have a Cold and Contractive Force, not only for the Reaſons Alledged, *Book* 1. *Chap.* 5. §. 21. but becauſe in a Total Eclipſe of the Sun, there is an Apparent Coldneſs and Chillneſs Introduced into the Air, which cannot be ſo well Accounted for by a bare Interception of the Sun's Rays, which we Experience in the Warmeſt and Darkeſt Nights, as by an Actual Impreſſion of Cold from the very Body and Subſtance of the Moon, which was very Senſible in that Famous Eclipſe, which was Total at *Cambridge*, where I now Write, and which happened on the 22*d* of *April* 1715. betwixt 9 and 10 of the Clock in the Morning; And when, by Looking upon it thro' a Small Teleſcope, without any Smoak't Glaſs, My ſelf, as well as ſeveral Others, in the Garden of this College, Diſcerned the Body of the Moon, as it came under the Sun, to be not of a Flat, but, Manifeſtly and Apparently, of a Globular Figure, which perhaps will be ſcarcely Credited by our Preſent Philoſophers; Tho' there are Arguments enough to Think it ſhould be ſo; Since, when the Side of the Moon, which is Obverted towards us, is ſtrongly Irradiated, there is a Wide Diſtance of it's Extremeſt Parts Obſervable by us, as in the Full Moon; And why it ſhould not be, in the other Two Sides, where the Rays of the Sun Paſs by them to the Eye, and therefore Receive Impreſſions from them, cannot be eaſily Imagined, or why we ſhould not ſee the Moon Globular, as well as any other Nearer and Leſſer Globe would appear ſo, if Interpoſed betwixt us, and a Lamp or a Candle. There was nothing Remarkable here in the Laſt Eclipſe, *May* the 11*th* 1724. betwixt 5 and 6 in the Afternoon, by Reaſon of the Clouds, which Intervened, unleſs a Gloomy Darkneſs, like that before Snow, and ſomething of Cold, which ſtill Confirms the Cold and Contractive Force of the Moon. But to Return to Anatomy.

THAT this is ſo, is farther Evident, becauſe, if this Contractive Force in the *Cruſta*, and the Downy Coat, is Diſſolved by the Expanſive one of ſtrong Liquors, Vomitings in the Stomach, and Diſorders in the Inteſtines, and a Dejection of Appetite Enſue, which cannot be owing to any Thing elſe, excepting to the Inmoſt and Nervous Coat, being from thence made bare, and thereby rendered too Tender to admit

mit the Impreſſions of any Expanſive Force, even from the Common Aliments only, which we take in for our Suſtenance.

Concerning the Conteſt betwixt the Expanſive and Contractive Forces in Forming the Coats of the Inteſtines.

§. 4. THE next Tunick, or Coat, which lies Immediately above the Nervous, or Inmoſt, is the Carnous or Muſcular, which conſiſts chiefly of a Fleſhy, Sanguineous, and Expanſive Subſtance, and runs over the Nervous Coat, which is of a Contractive one in order to be a Balance and Poiſe to it, after which comes the outer Coat, which is of a Nervous and Tendinous, and therefore of a Contractive Nature, and there the Oppoſition Ends; in which the Contractive has the Prevalence, or Superiority, which is Derived from the Brain and from the Male Principle, as the *Ovum*, the Aliment, the Blood, and the Nutritious Juices, are the Female Principle of our Animal Conſtitutions: And this ſeems to be the Reaſon of this Alternation of Forces; Firſt, there is the Brain from the *Semen*, and the Heart or Red-Beating Speck from the *Ovum*, the one Contractive, the other Expanſive, which begin the Competition of the Two Forces, by which the Animal Syſtem is Formed; After which there is the Aliment or Nutritious Juice ſupplied from the Mother, which is Expanſive, to Balance which the Brain or Contractive Force Extends it ſelf into the Nervous and Inmoſt Coat; which is again Counter-Acted by the Expanſive Force of the Carnous and Muſcular Coat; to Balance which the Nervous and Tendinous, and Outer, is Formed, and then the Æquilibrium is Perfected; in which, as the Contractive Force began, ſo it Ends the Conteſt; when the Expanſive has ſufficiently ſupported it ſelf againſt it, by a continual Infuſion of New Aliment and Nutritious Juices, which are all of an Expanſive Force: The Outer, Nervous, or Tendinous, Coat is very Thin, becauſe the Contractive Force in this Ferment or Contraſt is now Spent and Exhauſted, and therefore is ſparingly Spread upon the Expanſive of the Carnous or Muſcular.

How Dr. Gliſſon's, *and* Steno's *Notions of Fibres are Accounted for by this Doctrine, and the Reaſon of the Different Direction of Them in the ſaid Coats.*

§. 5. The Fleſhy or Muſcular Fibres, which are obſerved in the Second or Carnous Coat, and the Different Direction of them, are alſo Derived from the Contractive Force of the Nervous Subſtance; upon which Account Dr. *Gliſſon* Defines them in a Muſcle, to be in Figure like a Thread, Slender, Tenacious, Tenſile, and Irritable, and made of Spermatical Matter, which Deſcriptions agree with the Contractive Force of the Nervous Subſtance; and that which is properly Fleſh, is either a Sanguineous *Parenchyma*, Flowing thro' the Intervals of the Fibres, and Coagulated by their Cold or Contractive Force; or elſe, according to *Steno*, the Fibres are Vaſcular, knit cloſely together in the Tendon, and hanging more looſely in the Fleſhy Parts, and filled with a Fluid, I ſuppoſe a Sanguineous one; Be it, which it will, here are Evidently the Foot-ſteps of the Two Contractive and Expanſive Forces Contending with each other, and the Contractive or Nervous is Confeſs'd to be of a Spermatick Nature, as the Expanſive, of a Sanguineous, in Fleſhy or Muſcular Fibres: As to the Directions of theſe Fibres, the Outer Rank, in the Inteſtines, is of Strait ones, and the Inner of Circular or Spiral, and, in the Gullet and Stomach, they are nearly Analogous to the above-ſaid Directions, either by Spirals Interſecting each other, as in the Gullet, or by Strait or Oblique ones Interſecting the Circular, as in the Stomach; The Reaſon of which ſeems to be, that as the Aliment and Nutritious Juice or Blood is Progreſſive Downwards, upon the Account mentioned above, and at the ſame Time, by it's Expanſive Force, Exerts it ſelf into a Circumference from a Center, ſo, accordingly, the Nervous Subſtance by it's Contractive Force, Attending and Oppoſing the Former, is carry'd down in Strait Fibres, and caſts it ſelf likewiſe into Circular or Spiral ones to Balance and Poiſe thoſe Strait and Circular, or Spiral, Actions in the Expanſive.

The Reaſon of the Increaſe of the Nervous Subſtance, ſo as to Form the Brain, the Medulla Oblongata, *&c.*

§. 6. As to the Increaſe of the Contractive Force of the Spermatick or Nervous Subſtance, by which it is Enlarged into the Brain, the *Medulla Oblongata*, the *Spinal* Marrow, the Nerves and Nervous Coats, that ſeems to be owing to the *Albugineous* Liquor, that Sweats out of the Inmoſt Membrane of the *Uterus*, which is a Nervous one, and is Imbibed by the *Chorion*, which is Soft and Spongy, and from thence Convey'd into the *Amnion*; as alſo by the prevailing Force of the Contractive, by which it Converts ſome of the Nutritious Juices into it's own Nature, as the Contractive Force of Cold, or the Expanſive of Heat can do other Subſtances, which is Evident in Froſt and Fire, by which thoſe Forces are Exemplified.

§. 7. AFTER

The foregoing Reaſonings Confirmed by Dr. Harvey's *Experiments.* Dr. Gibſon's Anatomy. Chap. 33. Book 1.

§. 7. AFTER I had gone thus far in Explaining theſe Matters upon my own Principles, and from what Appeared to Me to be Rational, I was ſurprized to ſee my Reaſonings ſo exactly Confirmed from the Obſervations of the Great and Celebrated Dr. *Harvey*, the Firſt Aſſertor of the Circulation of the Blood, who, Diſcourſing concerning the Order of the Generation of the Parts in a Chicken, Says; There appears at the very Firſt, a Red Leaping *Punctum* or Speck, a Beating Bladder, and Fibres Drawn from thence containing Blood in them, and, as much as one can Diſcern by Accurate Inſpection, Blood is made before the Leaping Speck is Formed, and the ſame is endued with Vital Heat, before it is ſtirred by the Pulſe; and becauſe the Beating Bladder and the Sanguineous Fibres, that are Produced from it, appear Firſt of all, it is Conſentaneous to Reaſon, that the Blood ſhould be before it's Receptacles; Namely, the Content before its Container, and that this is made for the ſake of the other; He confeſſes it to be a Paradox, that Blood ſhould be made and moved, and endued with Vital Spirit, before any Sanguifying or Motive Organs are in Being, and that the Body ſhould be Increaſed before the Organs appointed for Concoction; namely, before the Stomach and Bowels are Formed; but neither of theſe are Greater Paradoxes, than that there ſhould be Senſe and Motion in the *Fœtus*, before the Brain is Compoſed, and yet he ſays the *Fœtus* Moves, Contracts, and Stretches out it ſelf, when there is nothing Conſpicuous for a Brain, but clear Water; 'Tis alſo owned, that the Mouth, Gullet, Stomach, *&c.* are gradually Formed in a *Fœtus*, that the Nutritious Juice enters by the Mouth, that it Receives no Blood from the Mother, nor is nouriſh'd by it; all which agrees Perfectly with what has been before Argued from the Contractive and Expanſive Forces, and which Paradoxes I have Endeavoured to Explain.

The Reaſon of the Different Cavities of the Gullet and Stomach.

§. 8. THE next Thing to be Conſidered in the Mouth, Gullet, Stomach, and Inteſtines is their Various Cavities, that of the Palate and Mouth we have already Accounted for; The Aliments or Nutritious Juices, being Repuls'd from the Contractive Force of the Brain, and the *Medulla Oblongata*, and *Spinal* Marrow, Deſcend down towards the Heart, or the Red Beating Speck; and by the Contractive Force Inveſting them, the Coats of the Gullet are Formed, with a Cavity not Conſiderable, by Reaſon of the Perpendicular Deſcent of the Aliment; but when in it's Progreſs it comes near the Heart, it is Detained by the Expanſive Force in ſome Meaſure, by it's Inclination and Propenſity towards it, being of a like Nature with it, yet being Repelled by the Contractive, which Attends it, and which ſtill Inveſts it with Coats and Membranes, it in part Circulates about it, and makes the Figure of the Stomach Lunar from the *Cardia* to the *Pylorus*, with the Concave bending towards the Heart; This Detention of the Aliment in it's Paſſage muſt neceſſarily Amaſs it together in Greater Quantities, and conſequently muſt Enlarge the Cavity of the Stomach; and for the ſame Reaſon it is more Capacious on the Left ſide, which is neareſt the Heart, than on the Right: And that Forces of the ſame Nature, whether Expanſive or Contractive, do Propend and Incline to each other, is Plain from the Magnet, Electrical Subſtances, and Glaſs, Attracting, and being Attracted by, Bodies of the like Kind; From Fire Drawing Flame to it, and the Eaſy Propagation of it thro' Hot Bodies, and the more Difficult thro' Cold; as alſo from the Mutual Gravitation of Heavy Bodies to each other, which have a Contractive Force, and from the Eaſy Propagation of Froſt and Cold thro' Phlegmatick and Groſſer Subſtances, and the more Difficult thro' Hot and Fiery ones, which have an Expanſive.

The Reaſon of the Small Guts, Venæ Lacteæ, *and* Meſentery.

§. 9. THE Contractive Force now Prevailing, after the Expanſive of the Aliment is driven from the Heart, thro' the Stomach, to the *Pylorus*, it Streightens it's Coats, Thickens it's Folds and Wrinkles, and Preſſes the Chyle, the more Expanſive Force of the Aliments, thro' it's Sides, into new Derivations, which being ſtill ſurrounded by the Contractive, the *Venæ Lacteæ* are Produced, and the Guts become Small in the *Duodenum*, the *Jejunum*, and *Ileum*; And to Fortify and Strengthen the Contractive of the Guts, Freſh Auxiliaries are ſent out from the *Spinal* Marrow, which Joining to the Contractive Force of the Guts, which is of the ſame Nature with it, the *Meſentery* is Formed and Connected with the Inteſtines; On the Contrary, to Balance in ſome Meaſure theſe Contractive Forces, the Bile, an Hot and Expanſive Liquor, is conveyed into the *Duodenum* from the Liver, together with the Pancreatick Juice from the Sweet-Bread, which, as Sweet, is of an Expanſive Nature, and Innumerable

Veins and Arteries from the Heart are Interſpers'd in the *Jejunum* and *Ileum*, which ſerve to the ſame Purpoſe, all which, in Conjunction with the Aliments, keep the Contractive Force from cloſeing the Guts, and ſhutting up the Inteſtinal Paſſage, by their Oppoſite and Expanſive Forces, which was almoſt done at the End of the *Ileum*, which hangs Lank and Flaccid into the *Colon*, as before Deſcribed.

The Reaſon of the Large Guts, of the Expulſion of the Fæces, *and why the Male Principle Prevails againſt the Female.*

§. 10. The Aliments now coming into the *Colon*, after the former Conteſt is Ended, being Deprived of their Principal Expanſive Force, the Chyle, are Changed into *Fæces*, which being of a more Contractive Nature, the Contractive Force of the Coats Acts leſs againſt them, becomes more Compliant, Widens their Paſſage, and Expands their Wrinkles and Folds; and there are Fewer Blood-Veſſels, becauſe there is leſs Occaſion to ſupport, from the Heart, the Expanſive of the Aliment, which is now Fæculent and Groſs, neither fit for the Sanguineous, nor the Nervous Subſtance, and therefore Ready and Prepared for Expulſion by them both.

But it muſt be Obſerved, that the Contractive Force, has from the Firſt to the Laſt, from the Entering of the Aliment into the Mouth, to the Excretion of the *Fæces* from the *Rectum*, by it's Inveſting and Incloſeing it, by Repelling it from the Heart, by Contracting it in the Small Guts, and giving a Greater Space and Room to it in the Large, ſtill Prevailed; That is, the Male Principle above the Female; and which is Agreeable to what is certain Matter of Fact, that the Solids, which are of a Contractive Force, are Greater, in Proportion, than the Fluids in the Animal Syſtem, and that Children, generally ſpeaking, more Reſemble the Father in their Features and their Diſpoſitions than their Mother; tho' the *Albugineous* Matter from the *Uterus*, may, when very Contractive, and the *Ovum* from the Mother, when very Expanſive, have a Different Effect, and make them carry ſtronger Impreſſions of the Maternal Qualities, where the *Seminal* or Male Principle is Weaker.

The Reaſon of the Circumvolution of the Small Guts, and the Circuit of the Colon *thro' the* Abdomen.

§. 11. As for the Circumvolution of the Small Guts in the *Umbilical Region* and *Hypogaſtrium*, it is agreeable to the Expanſive Forces ſtill Exerting themſelves, and the Contractive Forces Acting againſt them, the Firſt of which, when Reſiſted by the Laſt, muſt of Courſe find out new Turns and Ambages to avoid the Inſults of the Former.

The *Colon*, which is the Beginning of the Large ones, takes the whole Circuit of the *Abdomen*; for the Remaining Parts of the Aliment having ſtill an Expanſive Force, and the Contractive Force being Diminiſh'd, Tend again towards the Heart, Aſcending up on the Right ſide of the *Abdomen*, then Bending to the Left, and Running along the Bottom of the Stomach, and being Repelled once more from the Heart, by the Contractive Force of the Coats, they now Deſcend down the Left ſide of the *Abdomen*, Paſs from thence to the Right, and preſently after are carry'd into the *Rectum*, where they are at Length finally Excluded from the Human Syſtem by the abovesaid Contractive Force.

The Reaſon of the Blood-Veſſels and Nerves, and the Nature of the Glands.

§. 12. And ſuitable to the foregoing Account of the Inteſtinal Paſſage, the Brain ſends it's Nerves to ſupport the Contractive Force, and the Heart it's Arteries and Veins to ſtrengthen the Expanſive, thro' the whole Canal. As to the Glands already Deſcribed, the *Tonſillæ* or Almonds, the *Parotides*, the *Maxillar*, and *Sublingual*, it is Plain they are chiefly of a Contractive Nature, both by their Conglobations and Conglomerations, by their being ſuppoſed to ſeparate the ſerous Matter of the Arterial Blood, and to beſtow an Acid Quality upon it; and by the Large and Numerous Twigs of Nerves, which enter into their Compoſition; The Glands therefore are ſtrong Efforts of the Contractive Force, Derived from the Brain and Nervous Syſtem, and the Arteries found in them are Efforts of the Heart, and the Sanguineous, which are but Small in the Compariſon; and the Liquor, or Fluid, ſeems on that Account to be of a Cold and Contractive Temper, which is Derived from them, and not Separated from the Blood, which only Enters them to Oppoſe and Qualify their Contractive Force, but Made and Diſtilled from the Brain, and Convey'd into the Mouth to oppoſe the Expanſive of the Aliment there; and from whence Ariſes the Fermentation ſo much Celebrated, and almoſt univerſally Affirmed by Anatomiſts, and is the Beginning of Chylification, which is afterwards Perfected in the Stomach, and the *Duodenum*; To give an Account of which we ſhall now Proceed.

How Chylification is Performed.

§. 13. IT muſt therefore be Firſt obſerved, that the Aliments, which we take in at our Mouths, are endued with a certain Degree of Force, in Order to become ſuch; If the Expanſive is too Great, as in Fire, or the Contractive, as in Metals or Stones, it is Evident, that Subſtances of this Nature are no ways Adapted to give us any Nouriſhment, ſince we can neither Eat Fire, nor Digeſt Gold or Marble.

Subſtances of too Expanſive or too Contractive a Nature not fit for Chylification, but thoſe of a Middle Temper betwixt both.

FARTHER, any Hot or Spirituous Liquors on the one Hand, or any Cold and Phlegmatick Juices, as thoſe of Cucumbers, ſome kinds of Melons, *&c.* on the Other, are alſo Prejudicial to the Animal Frame; From whence it is Plain, that Liquids and Solids, of a Middle Temper betwixt both, and which have a due Proportion of each, are the moſt Agreeable to our Natures and Conſtitutions; And ſo they ought to be, If what we have before alledg'd is true concerning them, which, we have ſaid, Conſiſt of an Equal Balance of the Expanſive and Contractive Forces.

Fruits better than Meats, and Meats Boiled or Roaſted than Raw.

THUS the Fruits of Trees, in our own Climate, are Generally eaſily Digeſted, becauſe, as they Receive a Contractive Force from the Earth, out of which they Spring, ſo do they likewiſe an Expanſive one from the Sun, by which they are Raiſed to a certain Elevation above the ſaid Earth; and if ſome of them are of too Contractive and Cold a Nature, they are found to be more Wholeſome, by an Application of the Expanſive Force of Fire to them; Thus alſo Grain, which has a leſs Expanſive Force, and Riſes to a leſs Height from the Earth, wants the Grinding and the Baking, which adds to that Expanſive, before it is thought to be a proper Nutriment for the Body; 'Tis the ſame in Salads, which are Eſteemed to be of too Cold and Contractive a Temper, unleſs ſomething Warm, as Oil and Muſtard, which are of an Expanſive Force, are Joined with them. And in Meats or Fleſh, it is Evident by what foregoes, that they Conſiſt of a Nervous and Sanguineous Subſtance, that is of a Contractive and Expanſive Force, and the Reaſon, why Fire is apply'd to them, in the Boiling or the Roaſting of them, in order to make them more Conſonant and Agreeable to the Animal Oeconomy, is to Exalt the Expanſive Force of them, which are too Contractive from their Nervous Fibres; Roaſted are more Spirituous, Expanſive, or ſooner Digeſted than Boiled, becauſe the Expanſive of Fire is Greater than that of Hot Water; Hence alſo it is, that Fiſh, which have a Cold and Contractive Nature, Require the Expanſive of Wine.

Small Beer or Small Ale Preferrable to Strong Ales or Wines, or to Water.

THUS alſo in Liquids, Water is Eſteemed of too Cold and Contractive a Temper, Strong Ales, Wines, Spirits and Brandies, of too Hot and Expanſive a one, and both of them Prejudicial to our Conſtitutions; whereas Small Beers, and Small Ales, and Cyders, and other Liquors, which are Gently Fermented, that is, which Conſiſt of a Small Contractive Force, as Water, and which are Exalted into a Moderate Degree of the Expanſive, by the Infuſion and Fermentation of Grain, or Fruits, with it, which from Vegetation and the Sun's Influence are Endued with an Expanſive, are Allowed to be the moſt Wholeſome, and the moſt Friendly to our Natures.

Wines Preferrable to Brandies, and Red Wines more Eligible than White.

AND for the ſame Reaſon, Wines are Preferrable to Spirits or Brandies, and the Red Wines more Eligible than the White; Becauſe the Former, we ſpeak of Red Wines and White, have a Greater Degree of the Contractive Force mixt with their Expanſive, that is, are Cooler, and Leſs Hot and Expanſive, than the Latter; which may not be only Collected from the Red, having more Tartar than the White, but from the Taſt, which is more Rough and Subacid, and not ſo Sweet, Hot, or Spirituous; from the Colour, which is Deep and Purpleiſh, and is an Indication, all other Things being alike, that the Force is leſs Violent and Active, the White or Yellow, on the other Hand, Explains the Force to be more Fiery and Expanſive; as alſo from the Effects, the Firſt is Coſtive, the Laſt, Diuretick and Laxative, the Firſt drank Soberly occaſions no Diſorders, but comforts the Head and Bowels, the Laſt Heats the Blood, makes ſtronger and more laſting Impreſſions on the Brain, and deſtroys the Tone of the Stomach; and both Spirituous Liquors and Wines are always better, when Mingled, and Qualified, with the more Contractive Force of Water: This therefore ſeems to be a ſettled and fixt Rule for the Aliment of the Animal Syſtem, that it ſhould be Compounded of a Moderate Contractive Force joined with a Moderate Expanſive; ſo that in every Thing, which we take in for our Suſtenance, there are the Foundations and Principles of Fermentation and Diſſolution, and conſequently, in ſome Meaſure, of Chylification.

How the Aliment acquires a Greater Degree of the Expanſive, and is Oppoſed by the Contractive, from whence a Fermentation Ariſes and the Saliva is Produced.

Afterwards, when the Aliment is Received into the Mouth, if Solid, it is Chewed, Comminuted, and Macerated in ſome Meaſure by the Teeth, and in the Grinding acquires a certain Degree of the Expanſive Force, which Promotes and Aſſiſts that, which is Innate to it; In Fluids, where the Expanſive Force is Greater, there is no occaſion for ſuch Maceration or Comminution; the Expanſive Force in both is likewiſe advanc'd by the Heat and Expanſive Force in the Mouth, ariſing from the Fleſhy Muſcles of the Tongue, and the Carnous and Sanguineous Subſtance, with which the whole Cavity of the Mouth is Lined, which is all of an Hot and Expanſive Nature; On the other Hand, from the Brain and the Glands before Deſcribed, there is a Juice Imparted thro' the Salival Ducts, and thro' the little Glands of the Palate, which is of a Cold and Contractive Temper, which being Heated and Warmed by the Expanſive above-mentioned cauſes a Gentle Ebullition and Fermentation, as Water Boils with a Fire, or an Acid Ferments with an *Alkali*, and Raiſes the *Saliva* into little Bubbles, and a Froth, which mixing with the Aliment, a new Diſſolution enſues from the Intimate Fermentation Produced betwixt theſe Two oppoſite Forces, and with which it Proceeds thro' the Gullet into the Stomach.

That the Juices, which Diſtill from the Brain and Glands, which we have ſhewn to have a Contractive Force, are likewiſe of a Contractive one, is manifeſt from the Saltneſs and Coldneſs of them, and that Conſiſtency, which is Obſervable in the Phlegmatick or Purulent Matter, which is Derived from them, and is Excreted by our Noſtrils, or our Mouths, and which is a certain Proof of what Kind and Temper thoſe Juices are, of which this is the Excrement.

How the Aliment is ſo ſoon Diſſolved by the Mixture of theſe Expanſive and Contractive Forces.

That theſe Juices, mixt with the Expanſive Force of the Aliments, have ſo quick and ſudden an Effect in the Diſſolution of them, Proceeds from their being, tho' of a Contractive Nature, yet Exalted into a Degree of the Expanſive by the Spirituous Force of the Brain, from whence they Flow, and from whence they become leſs Contractive than Common Water, and put on a more Forcible Quality in Diſſolving the Aliment, which is already Expanſive, than Spirit of Nitre has in the Solution of Metals, which are vaſtly Contractive; On the Contrary, the Expanſive Force of Heat from the Blood Operates more Effectually upon the Aliment to the Fuſeing of it, than Fire can do in the Boiling of Meat in Water, becauſe it's Expanſive Force Ariſing from Blood, is more Fitted and Adapted to Diſſolve Blood, or Fleſh, or any other Aliment of the like kind of Expanſive Force, than Fire is, which is too Strong, and too Diſproportioned to it.

Why Spirituous Liquors or Hot Herbs are Prejudicial to Chylification.

From hence we may be able to give a Reaſon, why Spirituous Liquors, and high Seaſoned Meats, and Smoaking or Chewing of hot Herbs, are Detrimental to Digeſtion, becauſe they Spoil and Deſtroy the Nervous, Spirituous, and Contractive Juices, which Flow into the Mouth from the Brain, and Raiſe the Expanſive of the Heat and Blood to too Exorbitant a Degree for an Equal and Juſt Fermentation with the Contractive.

Why the Salival Juices are not an Univerſal Menſtruum.

Hence alſo we may be Informed, that theſe Juices are not an Univerſal *Menſtruum*, or Diſſolvent, but Adapted only to Aliments, which have certain Degrees and Proportions of the Expanſive and Contractive Forces; Likewiſe, that theſe Juices, being Formed from the Brain, and being of a Gentle, Spirituous, and Contractive Force, and meeting with the Expanſive, and from thence Producing a Fermentation and Diſſolution of the Aliment, are not to be conſidered, as a Spirit of Nitre, ſo that any Injury ſhould Ariſe from them to the Coats of the Stomach; Becauſe their Spirituous and Contractive Force cannot be Greater than the Nervous Syſtem, from which they are Produced, and from whence the Coats of the Stomach are alſo made; whereas Spirit of Nitre is a vaſt Saline and Contractive Force, Exalted into a Prodigious Degree of the Expanſive, and thereby capable of Diſſolving Metals, which theſe Juices cannot Stir or Move; Beſides which, the Diſſolution of the Aliment is not Performed barely by the Diſſolving Forces of theſe Juices, as a *Menſtruum*, but by their Fermenting with the Expanſive Force of the Aliment, and the Heat of the Sanguineous Syſtem.

How Digeſtion is Performed in the Stomach.

The Stomach is now Cloſed up, and the Aliments, which conſiſt of Meats Boiled and Roaſted, that is, of a Moderate Expanſive and Contractive Force, Moiſtened with the Fermented *Saliva*, and Mixt with the Small Beer taken in at our Meals, which has alſo a Gentle Fermentaceous Quality, are left to Digeſt in the Cavity of it; The

Heat of the Heart above, and of the Inteſtines below, and particularly of the *Colon*, which is filled with a warm Excrement, and which runs along the Bottom of the Stomach, very much Contribute likewiſe to the Maceration and Diſſolution of the Aliments into a Pulp, and ſo into a Chyle, by their Expanſive Forces; That is, Firſt of all, there is a Principle of Diſſolution in the Solid Aliments themſelves, both from the Contractive Force being Small, and from the Expanſive Force, which is Contained in them; Second, being Received into the Mouth, they are Broken and Comminuted by the Teeth, by which the *Saliva* Enters into their Subſtance, and again Rends and Tears it by it's Contractive Salts, Actuated by it's Spirit, Moiſture, and Fluidity, which are Expanſive, and thereby Repreſents a Milder Spirit of Nitre, which is alſo a ſtronger Salt, or a Contractive, Raiſed into a ſtronger Spirit and Expanſive by Fire; Third, the Expanſive of the *Saliva* is Increas'd by Fermenting with the Heat of the Mouth and Palate, and the Diſſolution of the Solid Aliments is farther thereby Promoted; Fourth, the Liquids Poured into our Stomachs at our Meals, by their Fermentaceous and Expanſive Force, and by their Fluidity, forward the ſaid Diſſolution, and the Heat of the Stomach, Heart, and Bowels, by their Expanſive, Compleats it, and Turns the Whole into a White Chyle, like Barley Broth, or a Milky Liquor; For all Expanſive Forces Act towards a Diſſolution, as all Contractive ones towards a Coagulation; Attrition therefore has nothing to do in this whole Proceſs, which is only a Creature of that Abſurd Philoſophy, the Atomical or Corpuſcular.

Why the Chyle is White, and how it is Gradually Changed into an Higher Expanſive in it's Paſſage from the Stomach, and Jejunum, to the Subclavian *Vein.*

THE Chyle is White and Milky from an Equal Balance betwixt the Expanſive Forces and the Contractive, that is, betwixt the Oily or Expanſive Forces of the Aliments, and the Saline and Contractive of the Nervous Juices, from whence no Particular Colour enſues, but a White, which is Indifferent to all, as we have ſhewn in our Philoſophy of Light and Colours; Thus an High Spirit of Nitre, mixt with Oil-Olive, and digeſted in a Gentle Heat for ſome Days, becomes of the Colour of Marrow, and afterwards Changes into a White Fat or Butter, according to Dr. *Grew*'s Experiment before Recited: The Chyle, being thus Formed in the Stomach, Paſſes thro' the *Pylorus* into the *Duodenum*, at the Bottom of which, and before it's Entrance into the *Jejunum* and the Lacteal Veſſels, the Bile from the Liver, and the Pancreatick Juice from the *Pancreas*, or Sweet-Bread, mixes with it, which are both of an Expanſive Nature, and the Former of them of an Hot and Fiery Temper; the Expanſive Force of the Chyle is therefore ſtill Augmented, with which it Tends to the Common Receptacle of it, and from thence it is carry'd thro' the *Ductus Thoracicus* to the Subclavian Vein, and ſo thro' the *Vena Cava* to the Heart, where it becomes of the Higheſt Expanſive Nature, and is Transformed into Arterial Blood to be diſpens'd thro' the whole Body.

How it is from thence Exalted into Blood, and Proceeds to the Heart.

FROM which it is manifeſt, that as the Contractive Force of the Aliment is Diminiſh'd, and the Expanſive Increas'd, it gradually Tends to the Common Receptacle, and the Thoracick Duct, and from thence to the Venal Blood, which Raiſing again it's Expanſive Force in the Subclavian, it urges it's way thro' the *Cava* to the Heart, the Seat of the Expanſive; and which is a Confirmation of what we before Alledged, that the Expanſive Force of the Aliment in the Stomach Tended towards the Heart, but was hindered in it's Progreſs to it from the Contractive and Nervous Syſtem, which Formed the Coats of it; The more Expanſive Forces of the Aliment being Directed this way, the more Contractive conſtitute the *Fæces*, which remain in the *Colon*, and are Expelled by the Periſtaltick or Vermicular Motion of the Guts, which we ſhall now Conſider.

The Periſtaltick Motion of the Inteſtines Accounted for from this Doctrine.

§. 14. IT has been ſhewn, that the Coats of the Inteſtines are Alternately Muſcular and Fleſhy, or Nervous and Fibrous, that the Fleſhy are Interwoven with Nervous Fibres, and the Nervous with Fleſhy ones, that they are likewiſe Endued beſides with Nerves, and Blood-Veſſels, both Veins and Arteries; from which Temperature and Complexion of them, it is manifeſt, that they conſiſt of a Sanguineous or an Expanſive Force, and of a Nervous or Contractive, which being nearly in an Equal Balance, and Acting againſt each other from the neceſſity of their own Natures, the Firſt from the Center or towards the Surface of the Body, and the Laſt from the Surface of the Body or towards the Center, cauſe a Reciprocation of Motion, by which the Cavity of the Inteſtines is Enlarged and Contracted by Turns; from whence in the Firſt Caſe, the Contents are Permitted to Deſcend, or Urge forwards, being Protruded by an Acceſſion of new Aliment behind, and in the Laſt they are Squeezed and Compreſs'd, ſo that one Part of them Proceeds, and the other Retires back, which upon a Second Enlargement and Dilatation or Expanſion of the Inteſtines, is again Urged forwards, and ſo thro' the whole Inteſtinal Pipe or Canal; which gives alſo an Account of what *Peyerus* has obſerved in all his Live Diſſections, that there is a Reciprocation of Motion in the Guts, Upwards and Downwards, and of the acknowledged Undulation of them; The Aliment alſo, and the Fermentations it undergo's, as before Deſcribed, makes this Periſtaltick or Vermicular Motion ſucceſſive from one Part to another, as it is Promoted forwards by it's Expanſive and Fermentaceous Force, and the Protruſion of New.

This Motion Agreeable to that of the Arteries, Muſcles, &c.

SUCH a kind of Motion, as this, is likewiſe Agreeable to what will be afterwards ſhewn to be that of the Arteries and Muſcles, and the other Parts of the Body; being a Gentle Pulſation, Ariſing from the Action of leſs Expanſive and Contractive Forces, as the other is a more Strong and Violent one, Derived from Greater.

Why the Fibres of the Carnous Coat are Circular or Spiral, and Direct or Linear.

THE Fibres of the Carnous Coat are Circular or Spiral, and Direct or Linear; Becauſe the Motion of the Guts, being Expanſive and Contractive in Circles, and ſucceſſive, Forms thoſe Intermediate Circles or Spirals ſucceſſively, and being Progreſſive or Regreſſive the Direct or Linear ones; For the Contractive or Quieſcent Force, of which Nature the Fibres are, muſt poſſeſs the Intermediate Spaces of Action, as in a Ferment, the Parts, which are the moſt Groſs and Contractive, are Separated from the Fermentation; or in General, as a Leſs Force ſubmits to a Greater; and it is Evident in the Carnous Coat, where the Sanguineous or Expanſive Force Prevails, the Nervous or Contractive muſt ſubmit in thoſe Directions of Circular or Spiral, or ſtrait Lines, which are Preſcribed to it; And in the ſame Manner, the very Creſts or Lines in our Hands are made by the Contraction and Expanſion of them. From this Doctrine it follows, that the Inteſtinal Paſſage in Various Animals may be Infinitely Vary'd, and that in a Worm or Inſect it may be Strait, without the Stomach, or the Circumvolutions of the Inteſtines, there being nothing more Required than ſuch a Paſſage for the Aliment, or the Expanſive Force, to be Diſtributed to the Syſtem.

CHAP. V.

Concerning the Liver, the Gall-Bladder, the Spleen, and the Pancreas.

An Account of the Liver, the Gall-Bladder, the Spleen, and the Pancreas, *by Anatomiſts.*
Syllabus Enterologiæ. Prælect. 2.
Dr. Gibſon's Anatomy, Chap. 11, 12, 13, 14, 15, 16. Book 1.
Dr. Keill's Anatomy, §. 11, 12, 13. Chap. 2.
Dr. Drake's Anthropologia Nova. Chap. 15, 16, 17. Book 1.
Blancard's Anatomia Reformata, Cap. 23, 24, 25.
Tauvry's Rational Anatomy, Chap. 8, 9.

§. 1. THE Liver is Seated in the upper Part of the *Abdomen*, about a Finger's Breadth Diſtance from under the Diaphragm, or Midriff, which Parts the *Abdomen* from the *Thorax*, in the Right *Hypochondre* under the ſhort Ribs, which, being of a Great Bulk, it in a Manner fills, and Reaches from thence towards the Left ſide, a little beyond the *Cartilago Enſiformis*, or Pit of the Stomach; It's Upper Side is Convex or Round, and Smooth, the Under is Hollow lying on the Right ſide of the Stomach and *Pylorus*, it's lower Edge reaches below the ſhort Ribs on the Right ſide, and very near as Low as the Navel before. In Dogs, and many other Brutes, it is Divided into Diverſe Lobes, but in Men it is Undivided and Continuous.

IT has Three Ligaments; Firſt, The *Suſpenſorium*, which Suſpends or Ties it up to the Diaphragm, and is Broad, Membranous, and Strong, Ariſing from the *Peritonæum*, and forming the outer Membrane of the Liver, into which it Deſcends, and is ſtrongly Faſtened to the Common Sheath, or *Involucrum*, of the *Vena Cava*, there where the Umbilical Vein is continued to it; Second, The *Umbilicale*, or Umbilical Vein, which after the Birth Cloſes up, and Hardens into a Ligament; It is Directly oppoſite to the Former, Paſſes out of the Hollow ſide of the Liver by the *Porta*, and Terminates in the Navel; by this the Liver is kept from Aſcending, upon the Motion of the Diaphragm upwards in Reſpiration; Third, The *Latum*, by which the Liver adheres to the *Cartilago Enſiformis*, it is Thin, and Flaccid, but yet Strong, Broad, and Doubled, Ariſing from the Membrane, wherewith the Liver is Encompaſs'd, and is a Duplicature of it; This hinders the Liver from Fluctuating to the one or the other Side, or towards the Back.

The Situation, Ligaments, Coats, and Subſtance of the Liver.

Besides theſe Three Ligaments, it has ſeveral other Connexions to the Neighbouring Parts by the Veſſels, that come into it or go out of it; It's Common Membrane, which is very Thin, Springs, as has been ſaid, from the *Suſpenſorium*, and Cleaves firmly to the Subſtance of the Liver, it is ſometimes Separated from it by a Wateriſh Humour, Iſſuing out of the Capillary Veins, or Lymphaticks, whereby Wateriſh Puſtules are Ingendred, and if theſe Break, and the Water Falls into the Cavity of the Belly, it is in ſome Part the occaſion of the Dropſy, called *Aſcites*; It's Proper Tunick or Membrane is that, which Inveſts each Lobe and Gland, which belongs to it; It's Subſtance, according to *Malpighius*'s Obſervations by the Microſcope, to which the preſent Anatomiſts Agree, Conſiſts of Innumerable Lobules, which commonly have each of them Six Sides like a Die, and are Formed of ſeveral little Hexangular Glands like the Stones of Grapes, and are each Cloathed with a Proper Circumambient Membrane, and are Joined to one another by Membranes continued from the Circumambient, and Running Tranſverſely, yet ſo, as that certain *Rimulæ*, or little Chinks, Reſult from the joining of the Sides of the Lobules together.

Of the Blood-Veſſels and Bilary or Excretory ones, and that they have no Anaſtomoſes, as alſo of the Glands.

The Whole Liver is made up of theſe Little Grape-ſtone-like Glands, and of diverſe Sorts of Veſſels, and therefore Reaſon concludes it neceſſary, that there ſhould be a Commerce betwixt theſe Glands and Veſſels, tho' Senſe cannot Diſcern the very ſlender Extream Twigs of the Veſſels, that are Inſerted into the Glands; It is farther Obſerved by the ſame Perſon, that the little Branches of the *Porta*, *Cava*, and *Porus Bilarius*, do run thro' all, even the leaſt Lobules in an Equal Number, that the *Porta* does the Office of an Artery, and has ſo Great Society with the *Porus Bilarius*, that both their Twigs are ſtraitly tied together in the ſame Cover; Alſo, that the Shoots of the ſaid Veſſels are not joined by *Anaſtomoſes*, by which the one opens into the other, but that the Grape-ſtone-like Glands are a Medium between the Importing and Exporting Veſſels, ſo that by the Interpoſition of theſe, the Importers Transfuſe their Liquor into the Exporters; From whence he Concludes the Liver to be a Conglomerate Gland Separating the Bile, and becauſe it is uſual for the Conglomerate Glands to have, beſides Arteries, Veins, and Nerves, a proper Excretory Veſſel, as in the *Pancreas*, *Parotides*, &c. Diſperſed thro' their Subſtance, Receiving and Carrying away the Humour ſeparated in them, this kind of Veſſel in the Liver is the *Porus Bilarius* with the Gall-Bladder; and tho' ſeveral Lymphatick Veſſels have been ſaid to Ariſe from the Liver, leſt it ſhould have a Double Excretory Veſſel, he thinks, that ſeeing in other Places the Lympheducts have not their Origin from Conglomerate, but Conglobate Glands, therefore they do not Spring from the Liver it ſelf, but from thoſe Conſpicuous Conglobate Glands, that are in the Hollow of the Liver under the *Involucrum* or *Capſula*, where the Trunks of the *Porta* and *Porus Bilarius* Enter into it; for as *Steno* obſerves, the Lympheducts of the *Parotides* do not Spring from them, but from a Conglobate Gland, which is Contiguous to them.

The Vena Cava, *and the* Vena Portæ.

It hath Two Sorts of Veins, in the upper Part the *Vena Cava* Entereth into it, and Spreads it ſelf all thro' it in the Lower, as well as Upper Part; into the Lower Side the *Vena Porta* is Inſerted, whoſe Branches likewiſe Run thro' it's whole *Parenchyma*, and ſerves for an Artery in bringing Blood to it, it's Proper Arteries being very Small and Few.

Of the Vena Portæ *or* Porta, *and the* Vagina Portæ, *or* Capſula Communis.

As to the *Vena Portæ*, or the *Porta*, from the πύλαι, where it Enters the Liver, and the Veins in General, the *Galeniſts* have Affirm'd them, and they ſeem, to have their Root in the Liver, tho' it is more Properly in thoſe Parts, where they Receive their Blood from the Arteries, than in the Liver or the Heart, whither they Convey it; but in Reſpect of the *Porta*, ſome Think, that the *Vena Umbilicalis* ought to be Accounted it's Root or Original, becauſe it is Firſt Formed in the *Fœtus*, and Inſerted into the *Porta*, but the Umbilical Vein, after the Birth, Degenerating into a Ligament, cannot from that Time be Eſteemed the Root or Origin of the *Porta*; Others therefore think, that, becauſe it's Branches, every where Inſerted into the Inteſtines, bring Blood from thence to the Liver, and not *Vice-Verſâ*, thoſe ought to be Accounted it's Roots, and it's Diviſions within the Liver, it's Branches, and ſo, ſtrictly, they ought to be Accounted; As it Enters the Liver, it is Inveſted with another Coat, which is called the *Vagina Portæ*, or Sheath, the *Capſula* or *Involucrum*, or it's Caſe or Cover, and the *Capſula Communis*, becauſe the *Porus Bilarius* is Involved in it, as well as the *Porta*.

A farther Deſcription of the Porta, *and an Account of it's Branches.*

THIS outer Coat it has from the Membrane, that Cloaths the Liver, tho' it is more Denſe and Carnous, with which all it's Ramifications are Inveſted, upon which Account, of it's having a Double Coat, upon it's Bringing Blood to the Liver for it's Nouriſhment, and upon it's being Endued with an obſcure Pulſation, according to Dr. *Gliſſon*, from the *Arteria Hepatica*'s Inſertion into the *Capſula*, it has the Nature of an Artery; A little within the Liver it Forms a *Sinus* or Heart, by it's Smaller Syſtole and Diaſtole belonging to it, and without which, it is hardly thought, the Blood would paſs out of the Larger Branches of the *Porta* into the Narrower, and ſo on into the Roots of the *Cava*; This *Sinus* is more Conſpicuous in an *Embryo*, becauſe the Great Influx of the Nutritious Juice, by the Umbilical Veins, Enlarges it, as is alſo the *Tubulus* or *Canalis Venoſus*, which paſſes Directly out of this *Sinus* into the *Cava*, almoſt oppoſite to the Mouth of the Umbilical Vein, that opens into the *Sinus*; This Canal or Pipe is of the ſame Subſtance and Texture with a Vein, and Enters into the *Cava* juſt as it Penetrates the Diaphragm, where Two other Great Branches out of the Liver are Inſerted into the *Cava*, and in the ſame Place this Pipe is alſo knit to the Suſpenſory Ligament, and after the Birth grows it ſelf into a Ligament; There are no Anaſtomoſes of the Capillaries of the *Porta* into thoſe of the *Cava*, according to Dr. *Gliſſon*, in his Book *de Hepate*, but the Blood Ouzes thro' the Glandulous *Parenchyma* of the Liver out of the Capillaries of the Former into thoſe of the Latter; After the Trunk has paſſed the Liver, it is Divided into ſeveral Twiggs and Branches; Namely, the *Cyſticæ Gemellæ*, the *Pylorica* or *Gaſtrica Dextra*, the *Splenica*, *Meſenterica*, *Ventricularis*, *&* *Coronaria*, the *Epiplois*, or *Omentalis*, *Dextra & Poſtica*, *Gaſtro-Epiplois Siniſtra*, *Hæmorrhoidalis Interna*, *Inteſtinalis* or *Duodena*, &c. ſo named from the Parts, thro' which they are Carried; Their uſe is to bring back to the Liver, from the Stomach and Guts, that Blood which Remains after their Nutrition, and which was brought to them by the Meſaraick Arteries, to be Circulated back by the *Cava* to the Heart.

A Deſcription of the Cava, *and of it's Aſcending and Deſcending Trunks.*

THE *Vena Cava*, from it's Large Cavity is that, into which, as into a River or Common Channel, all the other Veins like Rivulets, excepting the *Pulmonaria*, Empty themſelves; It's Root may be ſaid to be in the Liver, for by it's Capillaries it Receives the Blood, that is Tranſcolated thro' the Glandulous *Parenchyma* of the Liver, from the Capillaries of the *Porta*, and by it's Aſcending Trunk, which forthwith Enters the Diaphragm and Marches up the *Thorax*, Conveys it to the Right Ventricle of the Heart.

THE Capillary Branches of the *Cava*, as thoſe of the *Porta*, are ſpread thro' the whole Subſtance of the Liver; and the farther the Capillaries have their Origin in the Liver from the *Cava*, the Larger their Channel comes to be at their Arrival at it; but they do not all meet together in one Common Trunk within the Liver, as thoſe of the *Porta* do, but Empty themſelves apart into the *Cava* without the Liver.

THE Deſcending Trunk of the *Cava* is ſomething Narrower than the Aſcending, and Paſſing down along with the Great Artery, or the *Aorta*, continues undivided till the Fourth *Vertebra* of the Loins, before which there are ſeveral Branches from it; as, the *Venæ Adipoſæ*, for the Coat and Fat of the Kidneys, the *Emulgents*, which bring back to the *Cava* that Blood which the *Emulgent* Arteries carry'd to the Kidneys with the *Serum*, the *Spermaticks* or *Vaſa Præparantia*, and the *Lumbares*, for the Membranes of the Spinal Marrow; After which it is Divided into Two Equal Branches, called *Iliaci*, becauſe they paſs over the *Os Ileon*, as they go down to the Thighs; juſt about the Diviſion, there Spring Two Veins, the *Muſcula Superior* for the *Peritonæum*, the Muſcles of the Loins, and the *Abdomen*, and *Sacra* for the Marrow of the *Os Sacrum* and the Membranes that Cloath it; Afterwards the *Iliacal* Branches are again Divided into the *Interior*, from whence ariſe the *Muſcula Media* for the Muſcles of the Hip and Buttocks, and the *Hypogaſtrica* for the *Hypogaſtrium*, and into the *Exterior*, from whence the *Epigaſtrica* for the *Peritonæum* and Muſcles of the *Abdomen*, the *Pudenda* for thoſe Parts, and the *Muſcula Inferior* for the Buttocks; and then the Branches of the *Cava*, being paſſed out of the *Abdomen* into the Thighs, begin to be called *Crural*.

Nerves of the Liver.

BESIDES theſe Veins, the *Porta* and *Cava*, the Liver has Nerves alſo, but they are Extended only to the Membrane and Veſſels of it, as the Arteries were, ſo that the *Parenchyma* has but a very Dull Senſe.

Lymphedučts and Valves.

The Lymphedučts have not been yet obſerved to be Diſperſed in the ſaid *Parenchyma*, and *Malpighius* thinks they are not Derived from the Liver at all, but from the afore-named Conglobate Glands; They carry a moſt Limpid and Pellucid Juice from the Liver along the *Meſentery*, and open themſelves into the *Receptacle* of the *Chyle*; for in *Viviſection* make a Ligature about any one or more of them, and we may preſently ſee them Swell betwixt the Ligature and the Liver, but be Empty on the Side towards the Receptacle; Likewiſe there are Valves in them, which open towards the Receptacle and cloſe towards the Liver, and which hinder any Thing from Returning to it, and therefore are not Lačteals Conveying Chyle to the Liver in order to be Sanguify'd, as the Ancients Imagined: Theſe Lymphedučts are alſo obſerved to Cover the External Surface of the Stomach, and are Diſcharged into the Receptacle of the Chyle.

It's Office or Ačtion.

Hippocrates ſays, the Fountain of Blood is the Heart, the Place of Choler is in the Liver, which is thought to come very near the Truth; But the *Greeks* and *Arabs* generally held, that the Meſaraick Veins Received the Chyle from the Guts, and brought it to the Liver, by which it was Turned into Blood, which was carry'd from it into all the Parts of the Body by the Veins, but it is Plain, that none of the *Venæ Lačteæ* are Inſerted into the Liver, and conſequently, no Chyle is Imported into it; It's true Ačtion therefore is to Separate the Bile from the Blood, which is brought to it by the *Porta*, whether by Colature or Fermentation is Undetermined; *Ariſtotle* and the Ancients thought this Bile to be a mere Excrement, and of no uſe but, by it's Acrimony, to Promote the Excretion of the Guts; *Diemerbroeck* and the Moderns, on the other Hand, Eſteem it to be more than a mere Excrement, and therefore believe it to be a Ferment for the Blood and Chyle, made from the Blood Flowing into the Liver by the *Porta*, and Mixing with an Acrimonious, Saltiſh, and Subacid Juice, Formed in the Spleen, of the Arterial Blood Conveyed thither by the Arteries, and of the Animal Spirits by the Nerves, which is brought into the *Porta* by the *Ramus Splenicus*; by the means of which Acid Juice, and the Specifick Vertue or Cočtion of the Liver, the Spirituous Particles, both Sulphureous and Salt, lying hid in the Venous Blood, are Diſſolved, Attenuated, and become alſo a little Acrimonious and Fermenting; the Thinneſt Part whereof, like Clear Water, being Separated by the Conglobate Glands in the Hollow-ſide of the Liver, is carry'd off in the above-mentioned Lymphedučts: But the Fermentaceous Spirits of Greater Acrimony, mixt with the Thicker and more Viſcid Sulphureous Juices, and more ſtrongly Boiling, when they cannot Enter the Conglobated Glands, and yet thro' their Ebullition are Separated from the Blood, as Yeſt from Beer, become Bitter and are called Bile; which, being Tranſcolated thro' the Grape-ſtone-like Glands into the Roots of the *Porus Bilarius*, and Gall-Bladder, paſſes thro' them by the *Dučtus Communis* into the *Duodenum* or *Jejunum*; where mixing with the Pancreatick Juice, and the Alimentary Maſs Diſcharged from the Stomach, a Fermentation is Cauſed, by which the Chyle is Forced towards the Receptacle of it by Innumerable Lačteals in the above-mentioned Inteſtines; but the ſaid Fermentaceous Juice, being palled by Degrees in the following Guts, Chyle is more ſlowly Separated, and the Lačteals are therefore Fewer, and what Remains of this Fermenting Matter mixes with the *Fæces* in the Thick Guts, and by it's Acrimony Irritates them to Excretion; This farther is certain, that tho' the Liver does not Sanguify, yet it cannot be Eſteemed to ſeparate Bile as an Excrement only, becauſe it is a very noble Part, ſeeing the Diſeaſes of it are generally ſo Dangerous, and the Wounds in it are ſo Commonly Mortal; and by conſequence, that Liquor, which it Separates muſt have ſome noble Uſe, and ſuch as is very Neceſſary to Life.

It's ſeveral Bilary Veſſels.

The Bilary Veſſels, belonging to the Liver, are the Κύϛις Χολήδοχος, *Veſica Fellea* or *Bilaria*, or the Gall-Bladder, the *Porus Bilarius* or *Meatus Hepaticus*, the *Dučtus Cyſt-Hepaticus*, and the *Dučtus Choledochus* or *Communis*.

The Veſica Fellea *or* Gall-Bladder.

The *Veſica Fellea* or Gall-Bladder is about Two Inches in Length, and One in Breadth, by it's upper Part it Adheres to the Liver, and the Lower Reſts on the Right ſide of the Stomach and the *Colon*; It has Three Membranes or Coats, the outmoſt is Common with the Liver; the Middle is Thick and Strong, and conſiſts of Three Ranks of Fibres, the Outermoſt are Tranſverſe, the Middlemoſt Oblique, and the Innermoſt

Streight; The Inmoſt Coat is Nervous or Tendinous, Lined with a Glandulous one, and a Cruſt or Velvet upon it, as in the Stomach and Inteſtines; And the Glands ſeparate a Mucous Humour to Defend the *Veſica* from the Acrimony of the Bile: It has a Neck and a Bottom; The laſt is the Largeſt, and Contains the Bile or Choler, and is of the ſame Complexion with it, commonly Yellow, but ſometimes Greeniſh, Blackiſh, *&c.* The Neck, or *Meatus Cyſticus*, is the Narroweſt, being about as Wide, as a Gooſe Quill, and about Two Inches Long; betwixt this, and the *Veſica*, there is a Fibrous Ring, which ſtreightens the Paſſage, and hinders the too haſty Depletion of the *Veſica*; the other End of the Neck is Joined to the *Porus Bilarius*, and they both make the *Ductus Communis*, which is Inſerted into the Beginning of the *Jejunum*, or the End of the *Duodenum*: 'Tis a Controverſy with Anatomiſts, which way the Bile is Convey'd into the *Veſica*; Dr. *Cole*, with the Ancients, thinks it to be by the Neck from the *Porus Bilarius*, and to obviate the Objection of a Reciprocation of Humours in the ſame Veſſel, which is thought to be Abſurd, he ſuppoſes, that the Gall Paſſes out of the *Veſica* only upon the Diſtribution of the Chyle, but at other Times it is Received into it from the *Porus*, and Stored up there againſt the next Occaſion; Dr. *Gliſſon* on the other Hand, and the Moderns, believe that the Bladder is filled by it's Fibrous Roots, that are Diſperſed thro' the Liver, and that the whole Trunk of theſe Roots Enters that Part of the Bladder, where it is ſtreightened by the Fibrous Ring, tho' it is hardly to be Found or Diſcerned, which is not Strange, ſince the Inſertion of the *Ureters* into the Urine-Bladder are very difficultly Diſcovered: The Bile in the Gall-Bladder is Thinner, more Acrimonious and Fermentative, that in the *Porus Bilarius*, Thicker and Milder: The *Ductus Cyſt-Hepaticus* was found out by *Perrault*, whoſe Numerous Twigs are Diſperſed thro' the *Parenchyma* of the Liver, from thence they Aſſemble into Three Roots, and thoſe Unite into one Trunk, which has a Double Implantation, one into the *Porus Bilarius*, and the other into the Middle of the *Veſica*.

The Ductus Cyſt-Hepaticus.

Alphonſus Borellus de Motu Animalium, from the Continual and Speedy Efflux of the Bile by the *Ductus Communis* into the *Duodenum*, believes there is a Circulation of it; becauſe in a Day's Time, from a Perſon Faſting, there paſs Thirty Four Pounds of *Bilious* Juice into the *Duodenum* by the Common Duct, whereas the whole Maſs of Gall Amounts not to above Two Pounds; ſuch a Quantity he thinks cannot be Produced by way of Fermentation in the Liver, but that it is Separated Mechanically by Cribration from the Minute Veſſels of the *Porta*, thro' the Pores of the Glandules of the Liver, as the Urine in the Kidneys, and that this Circulation is Performed thro' the *Abdomen* by the *Vena Meſaraica* into the Trunk of the *Porta*, thence to the Liver, thence thro' the *Bilious* Veſſels into the *Duodenum*, to Return again by the Meſaraick Veins.

Veins, Arteries, and Nerves of the Veſica.

THE *Veſica Fellea* hath Two Veins, the *Cyſticæ Gemellæ*, which Spring from the *Porta*, it hath Twigs of Arteries from the Right Branch of the *Cœliaca*, and a Small Thread-like Sprig of a Nerve from the Meſenterical Branch of the Intercoſtal: Many Times Stones are Found in this Bladder, which are Lighter and more Spongy than thoſe of the Urinary, and will Swim above Water, which thoſe will not do.

The Porus Bilarius.

THE *Porus Bilarius*, or *Meatus Hepaticus*, which carries the Thicker Sort of Choler, paſſes Directly from the Liver to the *Ductus Communis*; within the Liver it's Trunk and Branches are Inveſted with a Double Coat, it's Proper one, which it Retains without the Liver alſo, and it's Common, Derived from the Membrane of the Liver, which wraps up the *Porus* and *Porta* together, and is called the *Capſula Communis*; It's Roots within the Liver are Equally Divided with thoſe of the *Porta* every where, excepting where the Roots of the *Veſica* are Spread, they are more Large and Numerous than thoſe of the *Veſica*, Drawing Choler from all the Parts of the Liver, ſaving whither the Roots of the Bladder Reach, tho' more Thick and Viſcous, and leſs Acrimonious; The *Porus* is Found in all Creatures, but the *Veſica* is Wanting in ſeveral, as Harts, Fallow-Deer, the Sea-Calf, and thoſe which have a whole Hoof, as an Horſe.

The Ductus Communis Choledochus.

THE *Porus* and *Meatus Cyſticus* Joining Form the *Ductus Communis Choledochus*, which, Piercing the outer Coat of the Inteſtine, paſſes betwixt that and the Middlemoſt, about the Twelfth Part of an Inch, and then Piercing that marches down farther betwixt it and the Innermoſt Coat about half an Inch, and at laſt opens with a Round Mouth into the Inteſtine; which oblique Inſertion ſerves Inſtead of a Valve to hinder any Thing Regurgitating out of the Gut into the Duct: There are no Anaſtomoſes or Inoſculations of the Roots of the Bilary Veſſels with thoſe of the *Porta*, they Terminate in the *Parenchyma* of the Liver, and Imbibe the Choler there Separated from the Blood.

THE *Ductus Communis* is ſometimes Inſerted at the Bottom of the Stomach, and then the Party Vomits Choler, and ſometimes at the lower End of the *Jejunum*, from whence follow *Bilious* Dejections; The Bile is generally Yellow, but in a Morbid State Degenerates into Pale-Colour'd, Eruginous, Porraceous, Vitelline, Reddiſh and Blackiſh, which is the Cauſe of very Violent and Acute Diſeaſes, as the *Cholera Morbus*, Dyſentery, Cholick, *&c.*

HAVING gone thus far in Recounting from Anatomiſts their Notions and Opinions of the Liver, the *Porus Bilarius*, and the Gall-Bladder; I ſhall Excuſe my ſelf the Trouble of Entering at preſent into the Deſcription and Uſe of the Spleen, and the *Pancreas*, which may be ſeen in the Authors, and the Places of thoſe Authors, whom I have Quoted, and if we can give ſome Solution of theſe Parts, from our Principles of the Expanſive and Contractive Forces, the ſame may be Extended to an Explanation of the Others.

How the Placenta, *or Womb-Liver is Produced.*

§. 2. To Account for theſe, or any other Parts of the Human Syſtem, it will be Neceſſary for us to look back to the *Ovarium* and the Womb, and the Formation of the *Fœtus* there; 'Tis therefore known, that after the Impregnation of the *Ovum* by the *Semen*, the Firſt of which we make to be of an Expanſive Force, and the Laſt of a Contractive, the *Ovum* is Inveſted with a White and *Albugineous* Liquor, and Two Membranes which Incloſe it, the Inner, which is the *Amnion*, and the Outer, which is the *Chorion*; the Liquor we ſuppoſe to be of a Contractive Nature, and is Aſſembled by the *Semen*, to Balance the Expanſive of the *Ovum*, and the Films or Membranes, which Surround them, are Condenſed into thoſe Coats or Tunicks by the Air, which is Included, and is of a Contractive Nature, having a like Effect upon the *Albugineous* Fluid, as a Colder or a more Contractive has upon Water, when it hardens it into Ice, or as Common Air has upon a *Lixivium*, when it Induces a Film or Cruſt upon it, or as the ſame Air has upon a Tough Phlegm, which it preſently Stiffens into a Skin. The Expanſive Force alſo in the Animal Syſtem Contributes to the ſame Effect, which makes the Contractive Force, if it cannot Diſſipate and Surmount it, to Coaleſce and Unite Cloſer together; That the *Albugineous* Liquor is likewiſe Contractive, ſeems Evident from the White of an Egg, which Coagulates upon the Application of the Expanſive of Fire or Hot Water to it, an Effect, which does not ſo ſoon obtain in the Yelk.

IN the mean Time, by the Glowing Warmth of the Womb, and of the Blood-Veſſels diſperſed in it, a ferment of this *Albugineous* Liquor is Cauſed, that is, by the Expanſive of the one Acting upon the Contractive of the other, from whence a Glandulous Subſtance Ariſes, or a Congeries of Veſicles or Bladders, as in all other Fermentations, and which by Degrees grow into a *Parenchyma*, which is called the *Placenta* or Womb-Liver; and as the Expanſive Force Prevails in this Fermentation, it is Attracted by, and Joins it ſelf to, the Womb and the Blood Veſſels of it; as all Forces of the ſame kind, whether Expanſive or Contractive, Unite with each other.

How the Liver is Formed in the Fœtus, *and it's Hexangular Veſicles or Glands, the* Porus Bilarius *and* Ductus Communis.

§. 3. WHEN the *Placenta* is thus Connected with the Womb, the Blood Contained in the Umbilical Veſſels Iſſues with an Expanſive Force, which is not to be Reſiſted, and is carried thro' the *Chorion* and *Amnion*, and the *Albugineous* Liquor Included in them, to the Expanſive Force of the *Fœtus*, which is afterwards the Liver, and is Removed at ſome Diſtance from the Contractive of the Brain; In this Paſſage the Expanſive Force of the Maternal Blood is Excited by an Oppoſition of the Contractive Force of the *Albugineous* Liquor, and becomes more Fiery and Expanſive from ſuch an Oppoſition, as Fire by an Affuſion of Water, or the Ventilation of Air; and with this Temper it Enters the *Fœtus*, and the Blood is Turned into an Hot Bile or Choler, and from thence Acquires it's Acrimony, and Yellow Colour, which are both Indications of it's Expanſive and Fiery Nature; Such a new Expanſive Force therefore Incurring into the Animal Syſtem, in order to Preſerve the *Æqui-*

librium of it, the Contractive Force is Increaſed by the *Albugineous* Fluid from the *Amnion*, which is conveyed into the Syſtem, and by the Aſſemblage of the Watry or Contractive Humours already in it, which the Brain had Collected for it's Support and Maintenance againſt the Expanſive of the *Ovum* and the Heart, theſe Contrary Forces Meeting, where the Umbilical Vein Enters the *Fœtus*, cauſe a Ferment there, and a Stoppage of both Liquors in the Conteſt, till the Liver is Formed, which from this Mutual Oppoſition Riſes into the Grape-like or Hexangular Glands or Veſicles before-mentioned, as Bubbles in a Fermentation, which, by the Air Included in the Syſtem, and by the Methods of the Expanſive and Contractive Forces before Deſcribed are hardened into Veſſels, which Surround and Contain by their Contractive Force the Expanſive of the Bile, which ſtill pouring in by the Umbilical Vein Proceeds towards the Heart, the Seat of the Expanſive; and being ſtill Reſiſted and Oppoſed by the Contractive Force, it is Inveſted with Coats, by which the *Porus Bilarius*, and it's Branches in the Liver, and the *Ductus Choledochus Communis* are Formed; which yield a Paſſage to the Expanſive Force of the Bile forwards, but Compreſs and Reſtrain it into Small Currents and Channels by their Force of Contraction; and which Coats are made from the Contractive, *Albugineous*, or Watry Humour, Condenſed by the Contractive Force of the Air Included in the Syſtem, and by that of the Nerves, which are Diffuſed in them, as alſo by the Contractive Cloſeing upon the Inſults and Action of the Expanſive.

Why there are Lympheducts found in the Liver, Gall-Bladder, Spleen, Pancreas, *&c. but not in the Guts or Inteſtines, the Reins, or in the Nervous Syſtem.*

§. 4. HENCE likewiſe it is, that the Liver, the Gall-Bladder, the Spleen, and the *Pancreas*, meet with Lympheducts in Great Plenty, being no where found in the Guts or Inteſtines; The Reaſon of which is, becauſe the Bile or Choler, as we before Obſerved, is of a Fiery and Expanſive Nature, and the Pancreatick Juice is Eſteemed by Anatomiſts to Aſſiſt to the ſame End and Purpoſe with the Bile in the *Duodenum* or *Jejunum*; It was therefore neceſſary to Preſerve the *Æquilibrium* of the Human Syſtem, that a *Lympha*, or Water, ſhould be Collected to thoſe Parts, which is of a Contractive and a Cooler Temper, in order to Rebate the Violence and Fury of the Expanſive in them; which Equal Balance in the Syſtem is as naturally Maintained, without ſuppoſing the Forces to Act by Choice or Inſtinct, as one Column of Water, which is Higher than another, Deſcends to a Lower, in the Caſe of Hydroſtaticks; becauſe the Expanſive and Contractive Forces muſt be Equally Poiſed in the Animal Oeconomy, or there will be a Diſſolution of it, and conſequently, if the Expanſive Prevails, as in the Bile, the Contractive, as in the *Lympha*, muſt of Neceſſity flow to it, to ſupport the *Æquilibrium*; upon the ſame Account we find a *Lympha* in the *Pericardium*, which Encompaſſes the Heart, and Lymphaticks Attending the *Arteria* and *Vena Pulmonaris* in the Lungs, but none in the Reins or Urinary Parts, nor in the Nervous Syſtem.

Why the Liver is ſo neceſſary a Part in the Human Syſtem, and why the Wounds in it are ſo Dangerous and often Mortal; and of the Nature of the Bile.

§. 5. As the Choler or Bile paſſes from the Liver into the *Jejunum* or *Duodenum*, and mixes with the Chyle, and is carry'd thro' the Lacteals of the *Meſentery* to the Receptacle of it, ſo the *Lympha* likewiſe is conveyed by it's Ducts from the ſame Bowel, thro' the ſame *Meſentery*, and to the ſame Receptacle, to Qualify and Moderate the Heat and Effervеſcence of the Bile, but ſtill to keep up a Ferment, by which the Chyle is Prepared, to be Exalted into Blood upon it's Mixture with the Venal Maſs in the *Subclavian*, and it's Entrance afterwards into the Heart; which ſhews how neceſſary the Liver is to the Human Syſtem, and Explains the Reaſon, why Wounds in it are ſo Dangerous and often Mortal; for tho' it do's not Sanguify, as the Ancients thought, yet it aſſiſts towards Sanguification, by Produceing the Bile, which is as Requiſite to the Forming of the Expanſive of the Blood, as the Chyle is; This Expanſive Force of the Bile alſo is that, which Precipitates, and Gives an Exertion of, the Chyle into the Lacteals with ſo much Activity and Vigour, as to leave the *Jejunum* commonly Empty, and by which the Aliment, and the Chyle, Receives a new Impreſſion of Volatility, and becomes ſtill more Fluid and Refined; Which, on the other Hand, Mixing with the *Fæces*, Diſſolves, Stimulates, and Urges them to an Expulſion, and if in too Great a Quantity, cauſes the afore-mentioned Bilious Dejections.

Why the Liver is of an Hot Temperature, and it's Colour

§. 6. THE Liver being thus Framed in the *Fœtus*, it is manifeſt it muſt be of an Hot Temperature and Conſtitution, and therefore we find it of a Yellower Colour than any other Entrail, which Approaching neareſt to the Colour of Fire, which is

the

Yellowiſh, and why the Umbilical Vein is Changed into a Ligament.

the Standard of the utmoſt Expanſive Force, is a certain Mark of ſuch a Force Reſiding in it; When therefore the *Fœtus* is ſeparated from the Womb, and the Maternal Blood ceaſes to flow thro' the Umbilical Vein, it is Contracted into the Umbilical Ligament; Becauſe, as we have ſhewn, the Coats of the Vein, or any Blood-Veſſel, have a Contractive Force, by which they Preſs Inwards, and there being no Expanſive Force of the Blood in the Cavity of it to Reſiſt that Contraction, it by Conſequence cloſes; On the Contrary, the Liver being of an Expanſive Force, and Surrounding it by Compreſſing of it, Aſſiſts to it's Contraction, and it is not Evident, that the *Suſpenſorium* and *Latum* might not be Originally Conduits, or, in ſome way or other, upon the Firſt Forming of the *Fœtus*, Receptacles of Blood, and Cloſed and Contracted in the ſame Manner; ſince the *Tubulus* or *Canalis Venoſus*, which Paſſes from the *Sinus* into the *Cava*, and is of the ſame Subſtance and Texture with a Vein, after the Birth is likewiſe Contracted and Cloſed into a Ligament.

The Reaſon, why the Blood Flows from the Inteſtines to the Liver after the Separation of the Fœtus *from the Womb, and how the Bile is ſtill Formed by the ſame Method of Nature.*

§. 7. However this ſeems to be Manifeſt, that, as this Bowel was Firſt made by the Influx of the Venal Blood from the Womb, ſo upon the Stoppage of that Influx, and the Separation of the *Fœtus* from it, it was Neceſſary it ſhould be ſupplied with ſomething Analogous to that Influx, for the Preſervation of the Animal *Æquilibrium*; which is the Reaſon, that the Blood Flows from the Inteſtines in ſmall Canals, and at length Meeting and Conſtituting the Trunk of the *Porta* Enters the Liver, ſince the Bilary Veſſels and Lymphaticks carry every Thing from it, and is a Solution, why the *Porta* does, in this Caſe, tho' a Vein, Perform the Office of an Artery in Conveying Blood to the Liver, tho' Veins in all others Conduct it back from the Parts, in which they are Implanted, to the Heart: And that Bile will ſtill be Produced is plain, ſeeing there is now an Aſſemblage of *Lympha* to this Part, and Lymphaticks Formed, which Contain it, there is likewiſe an Influx of Venal Blood, and moreover there is the Liver, which has an Hot and Expanſive Force belonging to it; and conſequently, the ſame Effect will be Obtained, as before from the Maternal Blood Paſſing thro' the *Lympha* or Liquor of the *Chorion* and *Amnion*, at leaſt by the Help and Aſſiſtance of the Natural Expanſive Force and Heat of this Bowel: Alſo the Blood Flows from the Inteſtines upon this Occaſion, where there is the leaſt need of it; the Conteſt there lying chiefly betwixt the Expanſive Force of the Aliment, and the Contractive of the Coats of thoſe Inteſtines.

Why the Liver is Round and Convex on the Upper-ſide and Concave on the Lower, and as to the Subſtance of it, it was before Explained.

§. 8. The Situation of the Liver, we have hitherto Explained, and ſhewn, that it muſt be Gathered and Contracted about the Umbilical Vein; The ſame Doctrine will alſo give us an Account of it's Figure, which on it's upper Side is Smooth, Round, and Convex, and on it's Lower is Hollow and falls into Edges, ſuitable to ſuch Concretions; for whilſt the Liver is Forming from the Coagulation of the Expanſive and Contractive Forces, and is kept and ſuſtained in the ſame Place, the Parts will Deſcend from above Downwards, and leave the upper Surface Convex and Smooth, and ſhape the Edges and Concavity below by their Natural Gravitation; For thus any Soft or Conſiſtent Subſtance, as Clay or Dough, if Round, and ſupported by the Finger, will fall into the ſame Figure; and that, if it were not for this Gravitation, and it's Support from the *Suſpenſorium*, the Liver would be Round, or Globular, may be Concluded from an Equal Balance of Forces nearly, from whence the Coagulation Enſues.

The Subſtance of the Liver, we have likewiſe ſhewn to be Glandulous and Vaſcular, and to be Repleniſh'd with an Hot Bile or Choler, made by the Paſſage of the Venal Blood thro' the Contractive Liquor of the *Chorion* and *Amnion*, and afterwards by the Venal Blood, and the *Lympha*, and the Liver it ſelf, which has now Contracted a Bilious, Hot, or Expanſive Force; And as to the Glands being Hexangular, that Proceeds from the Nature and Degree of the Contractive Force, which has been upon another occaſion Explained.

Malpighius's *Commerce betwixt the Glands and the Veſſels of the Liver not certain, nor*

§. 9. As to what is ſaid by *Malpighius*, that Reaſon concludes it neceſſary, that there ſhould be a Commerce betwixt the Glands and Veſſels, tho' Senſe cannot diſcern it, that does not appear ſo very certain; becauſe the Glands may be only ſmall Bubbles or Veſicles, Raiſed by the Fermentation, which Conſtitutes the Liver, and the Bile may Run betwixt them, or if it is Contained in them, it may by it's Ex-

that there are any Anaſtomoſes in it.

panſive Force break thro' the Sides of them, (which may again cloſe by their Contractive Force,) and enter into the Veſſels, which convey it to the *Jejunum*, and ſo to the Lacteals, and from thence to the Heart; It is not therefore Requiſite, that the Shoots of the *Porta* and *Porus Bilarius* ſhould be joined by Anaſtamoſes, nor that the Glands ſhould be the Medium betwixt the Importing and Exporting Veſſels, ſince nothing of this is Diſcovered by Obſervation, but it is Rational to Think, that the Bile is Spread thro' the Liver, and betwixt the Veſicles and Glands, as well as Contained in them, and that by it's Expanſive Force it from thence Enters into the Branches of the *Porus Bilarius*, and ſo is carry'd to the Lacteals and the Heart, to whoſe Expanſive Force it Preſſes.

In Relation to the little Branches of the *Porta*, *Cava*, and *Porus Bilarius*, Running in an Equal Number in the Liver, it Agrees with what we have Mentioned; the *Cava* being the Vein, and the *Porta* the Artery, and the *Porus Bilarius* the Conduit of the Bile, it has been alſo Explained, how the *Porta* comes to Perform the Office of an Artery.

Not Evident that the Liver is a Conglomerate Gland.

§. 10. But that the Liver is a Conglomerate Gland, is not Evident or Proved any farther than ſuch, as we have Repreſented it to be; Namely, that it Conſiſts of Glands or Veſicles, and of Innumerable ſmall Veſſels of the *Porta*, the *Cava*, and the *Bilarius* Diſperſed in it; and it is not Improbable but there may be Lymphaticks, tho' ſo Small as not to be Diſcovered by Obſervation, ſince a ſmall Affuſion of *Lympha* will Excite the Blood into Choler, and therefore is neceſſary to the Produceing it; and that this is ſo ſeems Manifeſt, ſince in Livers, which are Diſeaſed, there is not only a *Lympha* Collected on the outward Surface of it, but there are Bladders, filled with it, ſcattered about in it's Subſtance, which Proceeds from a Watry or Dropſical Conſtitution, when the *Lympha* is Aſſembled in too Great a Quantity to the Liver, and the Contractive is Prevalent over the Expanſive.

How the Lympha is ſupply'd to the Liver, and the Lympheducts Formed.

§. 11. We alſo conceive, that the *Lympha* is not chiefly carry'd to the Liver by the *Porta*, and mixt with the Blood, and then ſeparated from it to be convey'd off by the Lymphaticks, but that it is Originally drawn thither from the Liquor of the *Chorion* and *Amnion*, and afterwards ſupplied from the watry Steams of the *Abdomen*, which Ouze thro' and Moiſten the Subſtance of the Liver, and Increaſe the Heat and Ferment of it, and what Remains unuſeful to that Part is ſent in Veſſels to the Receptacle of the Chyle; and conſequently, when, as in an *Aſcites*, the *Abdomen* is full of Water, the Liver is Corrupted with too Great an Affluence of it, and not the *Abdomen* fill'd with a Diſtillation of the *Lympha* from the Liver, as is Taught by Anatomiſts; It is plain there is a *Lympha* in the *Abdomen* from the Diſtemper we call the *Aſcites*, and it is very Rational to believe, that in an Healthful State of the Body, there is ſome convey'd into it, which by the Heat of the Liver is Raiſed and Exhaled towards it, as Vapours by the Sun, that is, the Expanſive Force of the one is Ris' againſt and Oppoſed by the Contractive of the other, which coming to the Liver heightens it's Heat and Ferment, but when the Expanſive Prevails, theſe Steams are ſent off in Rivulets of *Lympha*, as Vapours fall down in Showers by the Prevalence of the Sun; And from hence it is, that theſe Streams of *Lympha* Ariſe from thoſe Conſpicuous Conglobate Glands, that are in the Hollow or Under-ſide of the Liver, where the Trunks of the *Porta* and *Porus Bilarius* Enter into it; for the Expanſive Force of the Liver Prevailing, Repells the Aſcent of the *Lympha*, and Determines it to a lower Situation at the Bottom of it's Subſtance, where it is carry'd off in Ducts made by it's obeying the Expanſive Force of the Bile and Liver, and the Contractive Force of the *Lympha*, and Included Air, and Nervous Syſtem.

Why the Parenchyma *of the Liver has but a Dull Senſe, and how the* Porta *is Inveſted with a Second Coat.*

§. 12. The *Parenchyma* has but a dull Senſe, there being few Nerves but what are Spread upon the Surface and Veſſels; which is Agreeable to the Account we have Given of it's Production from a Coagulum of Bile and *Lympha* after a mutual Conteſt betwixt the Expanſive of the Venal Blood and the Contractive of the *Lympha*, which are Liquors, that have no Senſe belonging to them; The Nerves by their Contractive Force aſſiſt to the Formation of the Membrane of the Liver, and the Coats of it's Veſſels, as well as to the Imparting a Senſe to them.

The *Porta*, when it Enters the Liver, is Inveſted with a Second Coat from the Membrane, with which the Liver is Encloſed, by an Adherence of the Contractive

Force of the Membrane to the Firſt Coat of the *Porta*, as Forces of the ſame Nature always Unite with and Propagate each other; and for the ſame Reaſon, the Portal or Arterial Blood, and the Bile, which are of an Expanſive Nature, join in Separate Channels under one Common *Capſula* or *Involucrum* in Oppoſition to the *Lympha*, and the Venal Blood of the *Cava*, which are of a more Contractive Temper.

Why the Porta *has an Obſcure Pulſation.*

§. 13. WHAT Dr. *Gliſſon* Obſerves of the Obſcure Pulſation of the *Porta* is eaſily Accounted for from the Principles we have Alledged for the Solution of the Periſtaltick or Vermicular Motion of the Inteſtines; ſince the *Porta* is Endued with a Double Coat, a Membranous and a Carnous, the Former of which has a Contractive Force, and the Latter an Expanſive, by which they Mutually and Reciprocally are Contracted and Expanded, which is the very Caſe of Pulſation; 'tis yet an Obſcurer one, than in the Arteries, becauſe the Blood, which is Aſſiſting to the Expanſive Force of the Carnous Coat, being Venal, has a leſs Degree of Expanſion than the Arterial, as will be afterwards ſhewn, and the Membranous Coat having but a ſmall Number of Nerves, has alſo a leſs Degree of Contraction, by which the Pulſation becomes Leſs Vehement, and Strong; On the Contrary, that this Obſcure Pulſation is owing to the Inſertion of the Hepatick Artery into the *Capſula*, which Dr. *Gliſſon* Thinks, cannot be Imagined, unleſs we can ſuppoſe, that little Twigs of Arteries are capable of Shakeing a whole Trunk, and Producing a Greater Motion in Larger Veſſels, than what is Experienced in Themſelves, which are Smaller.

Why there are no Anaſtomoſes of the Capillaries of the Porta *into thoſe of the* Cava.

§. 14. THERE are no Anaſtomoſes of the Capillaries of the *Porta* into thoſe of the *Cava* according to Dr. *Gliſſon*, nor ſhould there be according to the Principles above; ſince the Blood is Diſcharged from the *Porta* into the Liver to be Turned into Bile, which could not be, if there was a Continuation of the Capillaries of the *Porta* to thoſe of the *Cava*, and the Blood was carry'd on in one Channel; On the Contrary, when there is a ſufficient Quantity of the Influent Blood from the *Porta*, made into Bile, that is, when the *Lympha* and the Bilious Quality of the Liver, which it has Contracted by the Methods before Deſcribed, have Converted as much Blood into Bile, as their Forces are capable of Doing, the Blood, ſtill Flowing in by the *Porta*, is Returned by the *Cava* and it's Branches, whoſe Mouths lie open in the Liver ready to Receive it, as thoſe Mouths and the Cavity of the Branches were made and formed by the Expanſive Force of the Superfluous Blood, Preſſing towards the Heart, and the Coats by the Contractive of their Nerves, and of the Included Air; and perhaps the *Lympha*, being of a Contractive Force likewiſe, may be Aſſiſting to the ſame Effect.

The Aſcending Trunk of the Vena Cava, *and it's Root Accounted for, and why it is Wider than the Deſcending.*

§. 15. THE Root of the *Vena Cava*, as to it's Aſcending Trunk, it is very Probable, was originally in the *Fœtus* from the Umbilical Vein, which is Continued to it, aud after the Birth is Contracted into a Ligament, from thence the Capillaries of the *Vena Cava*, which Import the Superfluous Blood from the *Porta* into it, may be Accounted the Root of it; The Umbilical Blood went in a Current directly to the *Cava*, and by the Contractive Force of the Nerves had by Degrees a Coat, which Surrounded and Formed that Vein, but afterwards, when the *Porta* ſupplied the Blood to the Liver from the Inteſtines, and was ſpread in ſeveral Currents thro' the *Parenchyma* of it, the Superfluous Blood by it's Expanſive Force Tended back to the Heart in Various Channels, and conſequently Entered the Aſcending Trunk of the *Cava* in Different ones, to which Courſes of the Blood the Contractive Force of the Nerves and the Included Air, and poſſibly of the *Lympha*, gave their Tunicks, and Shaped them into Veins and Conduits for it's Conveyance; The Aſcending Trunk of the *Cava* is alſo Wider than the Deſcending, becauſe the Firſt was originally Formed by the Umbilical Vein, and by one Current and Influx of Blood made thro' the one into the other, whereas the Deſcending Ariſes from ſeveral and various Rivulets Emptying themſelves into it, according to the Diſtinctions of Branches before ſet Down and Deſcribed; which there is no Occaſion here any farther to Conſider, till we come to the Arteries, from whoſe Superfluous Blood theſe Branches of the Deſcending *Cava* are Conſtituted and Formed; in like Manner, as the Branches of the Aſcending are from the Superfluous Blood of the *Porta*, and in all Probability without any Imaginary Anaſtomoſes, which we ſhall then more fully Examine into.

Our Account of the Bile, and it's Sanguifying Quality Confirmed by Diemerbroeck.

§. 16. As to *Diemerbroeck*'s Account of the Bile, it very much Confirms what we have Propoſed concerning it, that it is made from the Blood of the *Porta*; He owns an Acrimonious, Saltiſh, and Subacid Juice Derived from the Spleen, and Formed by the Arterial Blood and Animal Spirits, which is Anſwered by our Contractive Force of the Air, and *Lympha*, Fermenting with the Expanſive of the Blood; He Confeſſes a Specifick Vertue and Coction of the Liver, we a Natural Heat and Expanſive Force of it, as before Explained: As to the Sulphureous and Salt Particles lying hid in the Venal Blood, we Acknowledge no ſuch Latent Qualities, but Think they are Produced, and that the Blood becomes Acrimonious and Fermenting, That is, that the Expanſive Force of it is Exalted, and Render'd more Fiery by the Methods above Specified: We likewiſe Imagine, that the *Lympha* is not only Separated from the *Porta*, but that it is Collected from the Cavity of the *Abdomen*, by which the Heat of the Liver is Increas'd above the Natural Temper or Expanſive of the Blood; that the Conglobate Glands do not Separate the *Lympha* from the Blood by way of Colature, but that the *Lympha*, Paſſing that way and being Excluded and Repelled from the Liver by the Expanſive Force of it, does by it's Contractive Force harden it into a Schirrous Fleſh or a Conglobate Gland, which Fleſh would otherwiſe have had a more Expanſive Force, that is, a Sanguineous one: How the Chyle is Urged towards the Receptacle of it by the Expanſive Force of the Bile, and ſo to the Heart, we have Explained before, which *Diemerbroeck* does not, who only ſpeaks of an Acrimonious and Fermentaceous Quality, in General, in the Bile, but does not Inform us, how that ſhould Protrude and Thruſt the Chyle towards the Receptacle of it: As to the Expanſive Force of the Bile, we Agree with him, that it is Diminiſh'd, the farther it goes from the Liver, and therefore has a leſs Effect in the Thick Guts, than it has in the Small ones, and by conſequence, that there are fewer Lacteals in the Latter than in the Former, and that it aſſiſts by it's Expanſive Force to the Excretion of the *Fæces*, we alſo acknowledge with him that the Bile is not an Excrement; On the Contrary, we ſay it Sanguifies, tho' not in the Liver, yet in Exalting the Expanſive Force of the Chyle upon it's Mixture with it, by which, and it's Entrance into the *Subclavian*, it is Transformed into Venal Blood, and by the Contractive Force of the Air in the Lungs, and the Pulſation of the Heart, into Arterial, as will be afterwards more fully Deſcribed.

The Reaſon of the Veſica Fellea, *or Gall-Bladder.*

§. 17. As to the *Veſica Fellea*, or Gall-Bladder, it ſeems to be Evidently ſupplied by it's Fibrous Roots from the Liver, not only from the Abſurdity of the contrary Opinion, but from this, that the Roots of the *Porus Bilarius* draw Choler from all Parts of the Liver, Excepting, whither the Roots of the Bladder Reach, which is a plain Argument, that the Choler there is Convey'd by thoſe Roots to the *Veſica*; Beſides there is a Reaſon for this *Veſica*, namely, the Conglobate Gland, and the *Lympha* Paſſing that way in a Greater Quantity, which being of a Contractive Force, is Equally Balanc'd by the Expanſive Force of the Bile Paſſing towards it in thoſe Small Roots, and which Collecting to an Head is Inveſted by the Contractive Force of the Air, and *Lympha*, and the Nerves, with it's Mucous and Tendinous Coat, and afterwards with it's Fibrous, to which the Liver adds it's Membranous; This alſo gives an Account why the moſt Active Part, and therefore the moſt Subtile and Acrimonious, of the Bile is Engaged in this Encounter, and Lodges in the *Veſica*, whilſt the more Viſcid, and Groſſer, is carry'd from the Liver by the *Porus Bilarius* to mix with the Chyle.

An Account of Borellus*'s Circulation of the Bile.*

Borellus De Motu Animalium, Prop. 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153. Cap. 10. Par. 3.

§. 18. I Think there is little more neceſſary to be ſaid in Reſpect of the Liver, the Bile, and it's Veſſels, as to Philoſophy, unleſs we conſider *Alphonſus Borellus*'s Circulation of it, which we ſhall now Inquire into: His Notion is, that the Glands are certain *Faſciculi* of Veſſels of ſeveral Kinds, of Arteries, Veins, Excretory Ducts, and Nerves; that there are no Anaſtomoſes of Arteries into Veins, becauſe there could be nothing then Separated from the Blood, which would Run in one continued Canal, nor yet of Arteries into the Excretory Ducts, becauſe then the Superfluous Blood could not be Received into the Veins; and that therefore it is neceſſary there ſhould be ſome Repoſitory of the Blood and Juices Different from the Veſſels, which Import or Export them; that the Imported Juices are mixt in theſe Repoſitories, and afterwards the Veins and Excretory Ducts Receive and Convey off thoſe, which are

Suited and Adapted to them; The Queſtion is, whether theſe Repoſitories of the Juices are mere Receptacles of them, or whether they obtain a Fermentative Quality, by which they Change and Alter the Blood Imported to them: Againſt their having a Fermentative Quality it is Objected, that Fermentation requires ſome Time to perform it in, and cannot poſſibly be Raiſed and Effected in the Momentany Paſſage of the Blood or Juices thro' them; that, by the Continual Flux of the Blood or Juices into the Glands, ſuch a Fermentative Quality would by Degrees be Impaired and Weaken'd, and at laſt be wholly Deſtroy'd, as a Vinegar Veſſel by a Continual Affuſion of Water looſes it's Acrimony; On the Contrary it is thought, that a Separation is made of Heterogeneous Fluids in the Glands Mechanically, thro' the Small *Foramina* of the *Faſciculi* of Veſſels, by way of Incuneation or Colature, where the Orifices of the Veſſels are Excavated Conformably to the Figure of the Blood or Juices, which they Receive.

As to the Bile, that it is made by the Liver is Confeſſed by all the Modern Anatomiſts, but whether by Fermentation, or Colature and Incuneation, is Diſputed; For the Firſt Opinion there are Two Reaſons Aſſigned: Firſt, Becauſe the Bilious Particles are very cloſely Embraced by the Blood of the *Vena Portæ*, and are not united by ſimple Contact; For in *Oximel*, the Vinegar, which is mixt with the Honey, by the ſimple Contact of Parts is ſenſible to the Taſt, whereas the Bitter and Bilious Juice, which is mixt with the Blood in the *Abdomen*, is not, it's *Aculei* being Entangled in the Glutinous Parts of the ſaid Blood, as Diſtilled Vinegar is Dulcified by Lead, or Powder of Coral; Second, Becauſe the Blood is not carry'd into the Liver with an Impetuous Motion, as it is in the Reins from the Emulgents, but Proceeds by a Gentle Diſtillation from the *Porta* into it, and conſequently, ſince a firm Connexion of Parts requires Time and Fermentation to ſeparate them, it is not Unlikely, but Nature may have taken that Method in Separating the Bile.

THE Laſt Opinion, that it is done by Incuneation or Colature is thus Defended; ſince, if it was Effected by Fermentation, there ſhould be a Fermentaceous Juice in the Liver, as Bitter as the Bile it ſelf is, or ſuch a Juice ſhould be Convey'd to it from other Parts; On the Contrary, the Liver is of a Sweet Taſt, and there are no ſuch *Vaſa Deferentia* in Experience or Obſervation; Beſides it ſeems very hard to Imagine, that a Fermentation ſhould be Raiſed in the ſmall Veſſels of the *Porta*, and in the ſtreight Pores of the Hepatick Glands.

BUT for the Mechanical Secretion of the Bile by Incuneation or Colature many Things may be ſaid; in the Firſt Place there is a *Vis Motiva*, namely, the Impulſe of the Blood from the Compreſſion of the *Abdomen* and the Air drawn in by our Breath; there is alſo a Continued Motion; there are the Small Canals of the *Porta*, and the Pores of the Glands; and there are Two Orders and Kinds of Veſſels for the Reception of the Different Fluids, the Venous, and the Bilary.

THIS being Premiſed, in order to Prove the Circulation of the Bile, he goes on to ſhew: FIRST, That only one Part of Blood, which is Leſs than the Twenty-Fifth Part of the whole Sanguineous Maſs, Paſſes thro' the Liver in one Circulation; Becauſe there is no other Blood enters into the *Vena Portæ*, and goes out of it, in the Time that one Circulation of the Blood is performed thro' the Heart, beſides that which is ſent into it by the Meſenterick and Cæliack Arteries; but the Diameters of thoſe Arteries are but $\frac{1}{5}$*th* of the Diameter of the Trunk of the *Aorta*, as it comes out of the Heart, and ſince the Circular Orifices are in a Duplicate Proportion of the Diameters, the Orifices of the Meſenterick Arteries will be $\frac{1}{25}$*th* of the Trunk of the *Aorta* Proceeding from the Heart; and the Bulk or Quantity of the Fluids, Circulating with the ſame Velocity, and in the ſame Time, have the ſame Proportion with the Orifices, thro' which they Paſs, that is, the Blood Flows with an uniform Velocity thro' all the Arteries.

SECOND, That the Bile, which is Collected by the Bilary Veſſels, does not ſeem to be Separated from the Sanguineous Maſs, out of, or which is Exterior to, the *Abdomen*; For if the whole Sanguineous Maſs, which does not uſually Exceed in Weight 20 *l.* was uniformly Tinged by the Bilious Juice, which does not commonly Exceed 2 *l.* That Part of the Sanguineous Maſs, which Paſſes thro' the Liver in one Circulation, can only be Purged of it's Bile, and therefore, by what foregoes, there can be only $\frac{1}{25}$*th* Part, or one Ounce of the Bile Separated from the Blood in the

Firſt Circulation, as there is only $\frac{1}{25}$*th* Part of the whole Maſs of Blood Paſſes thro' the Liver in that Circulation; and ſince that Part of the Blood, which is Purged of it's Bile, mixes afterwards with the whole Maſs, which is ſtill Tinged with it, in the Subſequent Circulations, there will be ſucceſſively $\frac{1}{25}$*th* Part of the Remaining Bile Purged or Separated from it.

If therefore a Calculation is made in the ſame Manner, as is done in the Excretion of the Urine, it will Appear, that after Six Hours, in the 100*th* Circulation of the whole Blood, $\frac{1}{250}$*th* Part of the whole Bile will be Separated by the Liver, that is, Leſs than $\frac{1}{10}$*th* Part of an Ounce; and after Twelve Hours, in the 200*th* Circulation, there is not Separated by the Liver more than 1000*th* Part of the whole Bile, or the 80*th* Part of an Ounce; and ſince the Bile is not Repaired, unleſs by taking in new Aliments, and what is Separated in the Liver is continually carry'd off by the *Porus Bilarius* and the *Ductus Cyſticus*, it would follow, that, after a Day's Faſting, thoſe Bilary Veſſels would be entirely Empty, but this is Falſe in Experience; For after ſeveral Days Faſting, nay ſome Months, the *Porus Bilarius* and Gall-Bladder in Serpents are Found as Full and Turgid, as Before; And therefore the Bile is not Separated from the Sanguineous Maſs, which is Circulated thro' the Arteries and the *Vena Cava*, that is out of the *Abdomen*.

Third, That the Bile, which is Separated by the Liver, upon Faſting, in the Space of one Day, is Sixteen Times More than that, which is in the Sanguineous Maſs: For the Bilary Veſſels are not like the Arteries or Meſaraick Veins, which End in Capillaries, but rather like the Branches of the *Vena Cava*, which, as Rivers, Form larger Canals from a Collection of ſeveral little Rivulets Falling into them; Thus the Bilary Veſſels, which carry the Bile from the Liver, have their Riſe from Capillaries, and End in Large Orifices in the *Duodenum*, and are always full of Bilious Juice; They are alſo like the *Vena Cava* in their Courſe, and in the Velocity with which the Fluids are Moved thro' both, the Impelling Cauſe of them being the ſame, namely, the Common Compreſſion of the *Abdomen*, and the Conſtriction of the ſame Circular Fibres; And ſince the Quantities, or the Bulks of the Fluids, which Paſs thro' Unequal Canals with the ſame Velocity, and in the ſame Time, obtain the ſame Proportion to each other, which the Orifices of the Veſſels have, the Bile, which is carry'd thro' the Bilary Veſſels to the Blood, which is carry'd thro' the *Cava* will have that Proportion; But the Diameter of the *Porus Bilarius* is not Greater than $\frac{1}{30}$*th* Part of the Diameter of the Greateſt Trunk of the *Vena Cava*, and the Diameter of the *Ductus Cyſticus* is of the ſame Meaſure, and therefore the Diameter of the One, will be to the Sum of the Diameters of the other Two, as 30 to 2, and the Circular Orifices, as the Squares of thoſe Numbers, or as 900 to 4, that is, the Circular Orifices of the Bilary Veſſels will be $\frac{1}{225}$*th* Part of the Circular Orifice of the *Vena Cava*, and the Fluids, which Paſs thro' the ſame Orifices in the ſame Time, will be in a like Reaſon; And becauſe, in every Circulation of the Blood, 20 Pounds of it are Tranſmitted thro' the *Vena Cava*, or 240 Ounces, therefore in the ſame Time, that one Circulation of the whole Sanguineous Maſs is Performed, there will Flow out of the Bilary Ducts $\frac{1}{225}$*th* Part of it, that is, ſomething More than one Ounce of Bile; Moreover, ſince in one Hour there are 16 Circulations of the Blood, in 24 Hours there will be Tranſmitted thro' the *Vena Cava* 7680 Pounds of it, and at the ſame Time $\frac{1}{225}$*th* Part, or 34 Pounds of Bilious Juice thro' the Bilary Veſſels, whereas the whole Bile, which is Contained in the Sanguineous Maſs, does not Exceed 2 Pounds, and therefore the whole Bile, which is Separated by the Liver upon Faſting, is 17 Times More than that, which is Contained in the Sanguineous Maſs, as 34 is 17 Times Greater than 2.

Fourth, That ſo Great a Quantity of Bile, as 34 Pounds, cannot be Generated in an Human Body upon Faſting by Fermentation; For he Thinks it cannot be Imagined, that the Bile ſhould be made by a Bilious Quality in the Liver, Changeing and Transforming the Blood into it, as Wine Turns to Vinegar, if put into a Veſſel, Infected and Tinged with that Liquor; Since it would be very Fooliſh and Abſurd in Nature to Corrupt that Blood into a Noxious Excrement, fit to be Separated and Expelled from the Animal Syſtem, which yet it had before taken ſo much Pains to Elaborate and Increaſe, and therefore ſuch a Procedure is Unworthy of it, which Acts all Things Wiſely and with Deſign.

From all which it is laſtly Concluded, That the ſame Maſs of Billious Juice, which is Diſcharged from the Liver is brought back, by a Circulation of it, to the Place from whence it began it's Motion, and it is Affirmed, that by the ſame Arguments, by which the Circulation of the Blood was Demonſtrated and Proved by our Celebrated *Harvey*, the Circulation of the Bile may be Evinced; For, as That is Inferred from the Heart's continually Pouring Blood into the Arteries, and from the whole Sanguineous Maſs, which in Men does not Exceed 20 Pounds, being Tranſmitted thro' the Heart in 3 or 4 Minutes of an Hour; ſo This is Aſſerted and Argued, from the whole Bilious Maſs not being Increaſed, where there is no new Acceſs of Aliment, from it's not Exceeding 2 Pounds, from it's conſtantly Flowing out of the Bile-Veſſels, and into the *Duodenum*, as alſo from ſomething Leſs than an Ounce of Bile Paſſing thro' the ſaid Ducts in the Time of one Circulation of the Blood; Since conſequently in the Time, in which 40 Circulations of the Blood are Performed, that is, in 2 Hours and an half, the whole Maſs of Bile, which does not Exceed 2 Pounds, is carry'd from the Liver into the *Duodenum*, that the ſame Effect may be continued from the Liver, it is neceſſary there ſhould be a Circulation of the Bilious Maſs.

After this we have Three Propoſitions; Firſt, That it does not ſeem Poſſible, that the Circulation of the Bile ſhould be Performed thro' the Heart by a Mixture of it with the Arterial Blood, but thro' the *Abdomen* only; Second, That there are Ducts, which may be Aſſigned, by which the Circulation of the Bile may be Performed thro' the *Abdomen*, that is, by the Meſaraick Veins; Third, That there is a Neceſſity and Uſe of the foregoing Circulation of the Bile, in Reſpect of which Propoſitions, I refer my Self to the moſt Incomparable Author.

The Circulation of the Bile Agreeable to and Confirmed by our Doctrine.

§. 19. As to the Circulation of the Bile, it is not only Rendered Probable and almoſt Certain from the Arguments above, but alſo from an Original Circulation of Fluids in thoſe Parts in the very *Fœtus*, Diſtinct from the Circulation of the Sanguineous Maſs, and Peculiar to them; Thus in the *Funiculus* or *Inteſtinulum*, beſides the *Urachus*, are Comprehended Two Arteries and the Umbilical Vein, by the Latter of which a Nutritious Juice, and ſome Blood, is convey'd from the *Placenta Uterina* to the *Vena Porta*, and ſo to the Liver, and by the Former, the Groſſer Part of the Nutritious Juice and Blood is carry'd back, and ſome of it Depoſited in the *Amnion*, to be Suck't in by the Mouth of the *Fœtus* for it's Nouriſhment that way, and the reſt is Returned to the *Placenta*; So that in the Firſt Formation of the Human Syſtem, here is a Circulation of Fluids from and towards the Liver, and therefore upon the Birth, when the Navel String is Cut, and that Circulation is Stopt, it is Reaſonable to Think, that Nature finds out a New way to continue the ſame Motions, or what are nearly Analogous to them, by conveying Blood to the *Vena Porta* from the Meſaraick Veins, and Returning it from thence, and the Liver, by the Bilary Veſſels.

This quick Circulation of the Blood and Nutritious Juices thro' the Liver in the *Fœtus*, will likewiſe Contribute to the Heat and Expanſive Force of it; and conſequently Confirms and Eſtabliſhes our Doctrine concerning it, and if the Bile afterwards is frequently Tranſmitted thro' the ſame Bowel, it Exalts that Expanſive Force and makes it capable of Converting Blood, which has a Leſs Degree of the Expanſive, into it's own Nature and Action.

That the Bile is not Separated from the Blood by a Colature, but made by the Expanſive Force of the Liver.

§. 20. Thus far therefore we Agree with this Celebrated Writer, but when he ſuppoſes, that the Bile is Separated from the Blood by a Colature in the Liver, he ſeems to be far from Truth, and his Arguments are as Weak, by which he Defends his Opinion: He ſays, that Fermentation Requires ſome Time to Perform it in, and cannot be Raiſed and Effected in the Momentany Paſſage of the Blood thro' the Liver.

To which we ſhall Firſt Anſwer from himſelf, that the Blood is not carry'd into the Liver with an Impetuous Motion, as it is in the Reins from the Emulgents, but Proceeds by a Gentle Diſtillation from the *Porta* into it, and conſequently, ſince a firm Connexion of Parts Requires Time and Fermentation to ſeparate Them, it is not certain, but Nature may have taken that Method in Separating the Bile; Second, We Anſwer, that to Convert Blood into Bile, it is not neceſſary to Imagine there is any Fermentation, but that the Action or Expanſive Force of the Liver is immediately Impreſs'd upon and Communicated to the Blood, as Fire, or the Expanſive Force of it, to Flax or Gun-Powder, without any ſuch Fermentation: He farther ſays, that by the Continual Flux of the Blood or Juices into the Liver, ſuch a Fermentative Quality would by Degrees be Impaired and Weakened, and at laſt be wholly Deſtroy'd, as a Vinegar Veſſel by a Continual Affuſion of Water looſes it's Acrimony; but if we conſider the Liver, as a Gentle Animal Flame, and the Blood, like a kind of Fuel, Convertible into it's Nature, this Objection will be of no Weight or Importance.

As to what is Alledged, that the Bile is Bitter, and therefore the Liver ought to be ſo, if it Made and Fermented, and did not Percolate the Bile, whereas the Liver is Sweet; It may be Anſwered, that Sweet and Bitter are only Various Degrees of the Expanſive Force, Acting upon the Palate and the Tongue; and conſequently, the Expanſive Force of the Liver, Exerting it ſelf upon that of the Influent Blood, may produce a Bitter, tho' the Liver is Sweet; as Fire can render Sweet Things Bitter, by Parching of them, and Impreſſing too Great a Degree of the Expanſive upon them, ſo as to make them Offenſive to the Taſt by their too Violent Action.

It is likewiſe thought hard to Imagine, that a Fermentation ſhould be Raiſed in the ſmall Veſſels of the *Porta*, and in the ſtreight Pores of the Hepatick Glands; but this Difficulty will Vaniſh with thoſe, who do not ſuppoſe the Bile to be Produced by Fermentation, but by an immediate Impreſſion of the Expanſive Force of the Liver upon the Blood Imported into it, by which it Changes it's Sanguineous Temperament into a Bilious one.

On the other Hand, there is Little urged on the Side of Colature or Incuneation: Excepting, that there is a *Vis Motiva* from the Compreſſion of the *Abdomen*, and the Air drawn in by our Breath; that there is a continued Motion; that there are ſmall Canals of the *Porta* and Pores of the Glands, and Two Orders of Veſſels for the Reception of the Different Fluids, the Venous and the Bilary; all which will be as neceſſary for the Circulation of the Bile, and carrying off the Superfluous Blood, which is not Converted into it, as for the Separating of it by Colature or Incuneation.

A Solution of the Pancreas, *and it's Juice.*

§. 21. As to the *Pancreas*, which Forms a Lymphatick Juice, which we reckon to be of a Contractive Nature, ſince it Contains Abundance of Volatile Salts in it, we may juſtly Eſteem it deſigned for an Equal Balance to the Liver in the Human Syſtem, in Preparing a Liquor of a Contractive Force, which ſhould be a Poiſe to the Expanſive of the Bile; and which it therefore Meets in the *Duodenum* or *Jejunum*, and Attends it in ſeveral Ducts to the Thoracick, and to the Receptacle of the Chyle, and from a Mixture of which the Blood may poſſibly owe in a Great Meaſure it's Red Colour, or a Deep Yellow, it's Flame and Heat, and it's Saltneſs and Volatility.

And it is not Impoſſible, but the Formation of it may be from another Gentler and Milder Fermentation within the Body of the Included Air, the Nervous Juice, and the Blood, From whence it's *Lobuli* and *Acini Glanduloſi* Ariſe; but as the Expanſive Force Prevailed in the Liver by the Great Influx of Blood Heated, ſo in the *Pancreas* the Contractive by the Nervous Juice and the Aſſemblage of *Lympha*; by which means it became capable afterwards of Converting the Fluids Imported into *Lympha*, as the Liver obtained the Quality of Changeing them into Bile.

The Nature of the Spleen, and it's uſe Explained.

§. 22. We ſhall only here add in Reſpect of the Spleen, *Lien*, or Milt, that it ſeems to be a Bowel made by Nature for the Excrement, or Effœte and Languid Part of the Bile, when it's Expanſive Force is Worn off and Spent, tho' Anatomiſts have hitherto been at a Loſs to aſſign a Uſe for it, whoſe ſeveral Opinions it will be too Tedious here to Recount, being either Contradicted in Fact or not Supported by Reaſon, as may be ſeen at Large in Dr. *Gibſon*; What therefore we are apt to believe is the Truth, is, that the Meſaraick Veins convey ſome Part of the Excrementitious or Languid Bile to the Spleen, where, when there is too Great a Quantity of it, it Lodges and Grows ſtill more Acid and Vapid; that from thence it is carry'd into the *Ramus Splenicus*, and ſo to the Liver, where it is again Exalted into Bile; And to Enliven the Bilious Excrement and Prepare it for New Bile, that the Influx of the Nervous Juice, and of the Blood, in ſome Meaſure Contributes;

This Account of the Spleen Agrees with *Borellus*'s Circulation of this Fluid, and Avoids all the Abſurdities, which are Chargeable, either upon the Hypotheſes of the Ancients, or thoſe of Dr. *Gliſſon*, *Velthuſius*, Dr. *Mayow*, *Blancard*, or Dr. *Havers* in his *Oſteologia Nova*.

AND from this Notion of the Spleen ſeveral Phænomenons may be Explained, which otherwiſe could not be; FIRST, That tho' there are Two or Three Spleens, out of each of them a Veſſel Paſſes into the *Ramus Splenicus*, that is, to convey the Acid or Vapid Bile to the Liver to be again Recocted into New Bile.

SECOND, That in Infants New-Born it is of a Red Colour, in thoſe of a Ripe Age ſomewhat Blackiſh, and in Old Men of a Leaden or Livid Complexion; Becauſe the Excrementitious or Languid Part of the Bile in Infants has the Greateſt Expanſive Force, in thoſe of a Ripe Age a Leſſer, or a Deeper Red, and in Old Men the Leaſt, or a Leaden and Livid, or Violet; For thus the Bile it ſelf has theſe Different Forces, being in Young Children more Hot and Expanſive, in Grown Perſons leſs ſo, and in Old Men leaſt of all, other Juices and Temperaments of the Animal Oeconomy being Equal; And in Conſequence of this, we find Children Hot and Froward, Men Sedate, and Old-Age Dull.

THIRD, From hence it obtains that Affinity with the Liver, which made *Hippocrates* and *Ariſtotle* Term it the Left, or the Baſtard one.

FOURTH, This alſo gives a Reaſon, why Wounds in it are commonly Mortal, as in the Liver, becauſe they are both Subſervient to the Forming of the Bile; and Obſtructions in it occaſion Grievous Pains, as it contains an Acid Liquor, which wants to be Raiſed into a Bilious one by Circulating thro' the Liver; the Stoppage of which Circulation, and the Contractiveneſs or Acidity of the Fluid Increaſing by it, muſt neceſſarily afflict the Patient in a ſenſible Manner; And yet if the Spleen is taken wholly away, there may no Great Inconvenience Enſue, becauſe then the Circulation will be Performed by the Meſaraick Veins, and there will be no Stagnancy of an Acid Fluid in the Cells and Glandules, which Compoſe it.

FIFTH, And therefore likewiſe it is, that the Fluids take ſo Tedious a March from the Spleen to the Liver by the *Ramus Splenicus*, whereas they might have been readily conveyed into the Trunk of the *Cava*, which lies near it, if the Juices, Elaborated or Lodged in it, had not been for the Service of the Liver.

LASTLY, Hence it is, that when the Quantity of Choler or Bile is too much Increaſed by an High or Luxurious Diet, or by Wines and Hot or Expanſive Liquors, Eager and Violent Paſſions are many Times Produced in the Mind; which are often Attended with a Sinking and Depreſſion of it, from a too Great Quantity of the Languid, Vapid, and Excrementitious Bile Stagnating in the Spleen, or at leaſt not Circulating ſo Expeditiouſly, as when there is a Leſs Load or Maſs to be Diſcharged from it thro' the *Ramus Splenicus* to the Liver; and which therefore cauſes Pains in ſome Meaſure Approaching to thoſe, which Reſult from Obſtructions in the ſame Bowel; which likewiſe, as the Liver and *Pancreas*, is Formed by the Fermentation or Conteſt betwixt the Expanſive and Contractive Forces, the Vaſcular Parts being made by the Contractive, and the Fluids contained, by the Expanſive. To Explain this a little farther; The Expanſive Force Acting from a Center, or Centers, Dilates it ſelf, by which a Fluidity or a Separation of Parts Enſues, the Contractive Force Tends towards a Center, or Centers, from whence a Solidity or Connexion of Parts Ariſes; And when theſe Two Forces meet together, it is neceſſary, in certain Circumſtances, that the Expanſive ſhould Exert it ſelf Outwards in the Contained, and the Contractive Exert it ſelf Inwards in the Container; That is, that the one ſhould be the Fluid, and the other the Veſſel, that the one ſhould Endeavour to Dilate and Expand it ſelf, and the other to Reſtrain and Encloſe ſuch Dilatation or Expanſion; And theſe Forces Acting againſt each other, the Contractive will ſurround the Expanſive, as being Superior in the Animal Syſtem, by what we have before ſhewn.

CHAP. VI.

Concerning the Meſentery, the Receptacle of the Chyle, the Thoracick Duct, and the Via Lactea, *or the Paſſage of the Chyle into the Blood.*

An Account of the Meſentery, the Receptacle of the Chyle, the Thoracick Duct, and the Via Lactea, *or the Paſſage of the Chyle into the Blood, by Anatomiſts.*
Syllabus Enterologiæ. Prælect. 3.
Dr. Gibſon's Anatomy, Chap. 9, 10. Book 1.
Dr. Keill's Anatomy, §. 7, 8. Chap. 2.
Dr. Drake's Anthropologia Nova. Chap. 12. Book 1.
Blancard's Anatomia Reformata, Cap. 22.
Tauvry's Rational Anatomy, Chap. 3. Part 1.

§. 1. THE next Thing to be Conſidered in the Animal Frame is the Meſentery, and the Paſſage of the Chyle into the Blood: The Account of which Former is, That it is ſo called from it's being placed in the Midſt of the Inteſtines, that it is a Membranous Part ſituated in the Middle of the Lower Belly, and ſerves both for Conveying Veſſels to and from the Guts, and Tying them together ſo, as they ſhould not be Entangled aud Confounded; It is not above a Span diſtant from the Center to it's Circumference, and yet in that it Comprehends all the Guts, excepting the *Duodenum* and Part of the *Rectum*, which are about Nine or Ten Yards in Length; It is almoſt of a Circular Figure, which is the moſt Capacious, and tho' it be Narrow and Plain at it's Riſe, it's Circumference is Wrinkled and Enlarged into ſo many Folds, as to be Three Ells in Extent; It has a Double Origin, the Higher is at the Firſt, and the Lower at the Third *Vertebra* of the Loins; It is Compoſed of Two Common Membranes, which are Propagated or Continued from a Duplicature of the *Peritonæum*, and betwixt theſe Two it has a Third Membrane, which is Proper, and is Thicker than either of the other, in which the Glands are Seated, and by which the Veſſels are Conducted; It is Stuffed with Fat betwixt it's Membranes, tho' in Dogs, Cats, and ſuch like Animals, this Part is very Thin and Tranſparent, in Human *Embryos* there is None, and in Lean Perſons but Little; It's Common Parts are Veins, Arteries, Nerves, and Lympheducts, and it's Proper are Glands and the *Venæ Lacteæ*.

The Veins and Nerves of the Meſentery.

THE Veins are called *Meſaraicæ*, and are Branches of the *Vena Portæ*, and the Arteries are Branches of the *Arteria Meſenterica*, and Paſs as the Veins do.

THE Nerves are thus Accurately deſcribed by Dr. *Willis*, in his Book *De Cerebro*, *Cap.* 25. As ſoon as the Intercoſtal Pair is Deſcended as Low, as over againſt the Bottom of the Stomach, it ſends forth on each Side a large Meſenterick Branch, each of which is again Divided, and makes Two *Plexus*'s in each Side; in the Middle of theſe is the Greateſt *Plexus* of all, which, as he ſays, is like the Sun amongſt the Planets, from which Twigs and Numerous Fibres are Diſperſed into all the Parts of the Meſentery, which accompanying the Sanguiferous Veſſels in their whole Proceſs, do Climb upon, and Twiſt about them; It has likewiſe, according to *Spigelius*, other Nerves, which Spring from the *Spinalis Medulla* between the Firſt, Second, Third, and Fourth *Vertebræ* of the Loins.

The Lympheducts of it.

THE Lymphaticks or Lympheducts, according to *Tho. Bartholin*, a Learned *Dane*, who Firſt found them out, and that not many Years ago, are of Figure Long and Hollow like a Vein, but very Small and Knotty, having many Valves, which Permit the *Lympha* or Water to Paſs to the Chyliferous Veſſels, and to ſome Veins, but hinder it's Return; They are of a Pellucid and Chryſtalline Colour, conſiſting of a Tranſparent and moſt Thin Skin, which being broken, and the *Lympha* Flowing out, entirely Vaniſhes; They are almoſt Innumerable, and according to *Malpighius*, always have their Riſe and Proceed from Glands, but according to *Steno*, they either Riſe from or are Inſerted in them; He farther ſays, that there are Three Sorts of Them; Firſt, Such, which from their Origins, but what thoſe are he does not Determine, are Diſperſed over the Surface of the Firſt Glands they Approach unto; Second, Such, which Run from the Hollow Side of one Gland to the Gibbous of another; And Third, Such, which Run from the Hollow Side of the ſaid Glands to the Veins, into which they Diſcharge their *Lympha*; As to their Inſertion, it is Agreed by Anatomiſts, that Thoſe under the Midriff Diſcharge their Liquor into the Receptacle of the Chyle, Thoſe in the *Thorax* into the Thoracick Duct, and Thoſe of the Neck, Arms, *&c.* into the Jugular Vein; It is alſo Affirmed by *Diemerbroeck*, that they open into many other Veins, and for which he Cites *Steno*; *Frederick Ruyſch* likewiſe, his Country Man, Aſſerts, that by Ligature and Structure of the Valves, he has plainly ſeen, that all the Lympheducts in the Lungs do carry their *Lympha* into the Subclavian, Axillar, and Jugular Veins.

What the Lympha is and it's uſe, according to Anatomiſts.

WHAT this *Lympha* is, is much Diſputed, *Bartholin* thinks it to be mere Limpid Water, with which is mixed a Thinner Part of the Chyle fit for Nutrition, and that the Former is thrown off by Sweat, and the Latter carry'd on by Circulation; *Gliſſon*, that it is a Liquor Condenſed from the *Halitus* of the Blood, like Dew, Driven into theſe Veſſels, and Flowing back with the Vehicle of the Aliment brought by the Nerves; *Segerus* and *Sylvius*, that it is the Animal Spirits, or is made of Them, which being Diſtributed into all Parts by the Nerves, are partly there Diſſipated and Conſumed, and partly Condenſed into this Water; *Diemerbroeck*, that it is a Fermentaceous Liquor, Separated from the Serous Part of the Blood in the Conglobate Glands, yet not Simple, but Impregnated with much Fuſed and Volatile Salt, and alſo with ſome Sulphureous Particles, which, when it is convey'd to the *Vaſa Chylifera*, makes the Chyle Thinner, and apt to Dilate eaſily in the Heart, and when to the Veins, Prepares likewiſe the Venous Blood, now grown Thick, for ſuch Dilatation; This is certain, that it Differs from the *Serum*, for if a Little of it is gathered in a Spoon, and ſuffered to Stand, without ſetting it over a Fire, it will Turn to a Jelly, which the *Serum* will not do; Some of the Lympheducts of the Meſentery paſs only thro' it from other Parts, as from the Liver, *&c.* but Many have their Riſe in it.

The Glands of the Meſentery.

IT has many little Softiſh Glands, fixed in it's Proper Membrane Covered on each Side by the Two Common ones, and beſet with Fat, out of which, when Cut, may be Squeezed a Whitiſh Liquor; They are Whiter in Young People than in Old; and in Men Fewer and Smaller than in other Creatures; The Biggeſt is at the Riſe or Center of the Meſentery, called by *Aſellius*, tho' Improperly, the *Pancreas*, into which all the *Venæ Lacteæ* are Inſerted; When theſe Glands grow Schirrous and Hard, or are any ways Obſtructed, ſo that the Chyle cannot be Strained thro' them, there follows a *Fluxus Cœliacus*, or *Chyloſus*, upon a Continuance of which, an Atrophy enſues, and the Party dies Tabid; and perhaps, it is ſaid, from the ſame Obſtruction, by which the Courſe of the *Lympha* is ſtopt, and the Lympheducts by an over Extention burſt, an *Aſcites* is partly cauſed.

It's Venæ Lacteæ, *and their ſeveral Kinds.*

THE *Venæ Lacteæ*, or Milky Veins, ſo called from the White Colour of the Chyle, which they carry, were firſt Diſcovered by *Caſpar Aſellius* in the Year 1622, upon Diſſecting a Live Dog; They are ſlender Pellucid Veſſels, having but a Single Coat, Diſperſed in Great Numbers thro' the Meſentery; Their Riſe is from the Inmoſt Membrane of the Inteſtines, where their Mouths are hid under a kind of a Spongy Cruſt, or *Mucus*, thro' which, by the Preſſion of the Guts, the Chyle is Strained and Received by the Mouths of theſe Veſſels; From whence they Proceed the Readieſt way to ſuch Glandules of the Meſentery, as are neareſt to Them, but in their Paſſage many Small ones, uniteing to one another, do commonly grow into one Large Trunk, namely a Pretty way, before they Inſinuate themſelves into the Gland, but in their very Entrance into it, or a Little before, this Trunk Separates again into New Branches, More and Smaller than the other, and thus far they are called *Radicales*, or *Primi Generis*; Out of the Gland there Spring again New Capillary ones, which by and by Meeting together make one Trunk as before, which, keeping it's Courſe towards the Center of the Meſentery, Enters as many Glands as lie in it's way, being Divided into New Branches, juſt before it's Entrance into each Gland; but whilſt all the Trunks Bend one way, they alſo, Meeting with one another, do in their Proceſs, ſeveral of them, Grow into one, and at Length all the Trunks Arrive at the Great or Middle Gland of the Meſentery, call'd Improperly the *Pancreas* by *Aſellius*, which moſt of them Enter into, but ſome of them paſs over it's Surface, and preſently after, They all Empty themſelves into the Great or Common Receptacle of the Chyle, that lies behind the ſaid Gland; Thoſe that were Inſerted into it Riſing out of it in like Manner, as they did before out of the Leſſer Glands; As they Run from one Gland to another, they are called *Secundi Generis*; and from their having paſſed all the Glands to their opening into the Common Receptacle, they are called *Tertii Generis*.

The Common Receptacle of the Chyle.

THE Common Receptacle and the *Ductus Thoracicus* were Firſt found out in Horſes, by *Bartholomæus Euſtachius*, as Appears by a Book he Writ *Anno* 1564, but the true Uſes of them were Firſt aſſigned by *Pecquet Anno* 1651; It is called the Common

Receptacle, becauſe it Receives both the Chyle and *Lympha* Promiſcuouſly; the Latter of which continues to Glide into it, after the Former is all Diſtributed, and to Aſcend by the *Ductus Chyliferus Thoracicus*, which therefore might as juſtly be Termed *Lymphaticus*; It is ſeated under the Celiack Artery and Emulgent Veins, about the Middle Diſtance between the Kidneys, and the *Capſulæ Atrabilariæ*, upon the *Vertebræ* of the Loins, for the moſt Part rather towards the Left Side; *Pecquet* and *Caſpar Bartholin* Affirm, that 'tis alſo Situate betwixt the Tendons or Appendices of the Diaphragm, by the Motion whereof it is Preſs'd, and the Contents of it Propelled; It is of a Membranous but Thicker Subſtance in Men than in Brutes, but not ſo Capacious, ſeldom being ſo Large, as to admit one's Finger's End.

The Ductus Thoracicus.

Out of it there Springs a Duct, that preſently Aſcends up into the *Thorax*, behind the Deſcending Trunk of the *Arteria Magna*, where it begins to be called *Ductus Thoracicus*, which, according to *Sylvius*, might be more fitly called *Spinalis*, as it runs along the Inſide of the *Spina Dorſi*; This Duct, having paſs'd the Midriff, Marches upward under the Great Artery, to about the Fifth or Sixth *Vertebra* of the *Thorax*, where it Turns a little Aſide from under it to the Left Hand, and ſo underneath the Intercoſtal Arteries and Veins, and the Gland *Thymus*, it Aſcends to the Left Subclavian Vein, into whoſe Lower Side it opens, juſt there, where the Left Jugular Vein enters into it on the Upper Side, ſo that their Mouths face one another; but it opens not into this Vein with any Large Orifice, but by Six or Seven little Ones, which are Covered in the Cavity of the Subclavian with one Broad Valve, looking towards the *Cava* from the Shoulder, whereby there is Granted to the Chyle and *Lympha* a free Paſſage out of the *Ductus Chyliferus* into the Subclavian, but their Return out of the Vein into the Duct is Prevented, as well as that of the Blood Contained in the Subclavian; The Duct ending thus in the Subclavian, the Chyle, which it Conveys, Paſſes with the Blood, Returning by the *Cava*, into the Right Ventricle of the Heart; This Duct has many *Semilunar Valves*, that hinder the Aſcending Chyle and *Lympha* from Deſcending back again, which *Valves* are thus Diſcovered, becauſe the Chyle contained in the Duct may eaſily be Preſſed upwards, but by no means downwards.

The Difference betwixt the Venæ Lacteæ *and the Meſaraick Veins.*

The *Venæ Lacteæ* differ from the ordinary Meſaraick Veins; First, In Bigneſs, for the Meſaraicks are Bigger, but the *Lacteæ* are more in Number; which is thought to be neceſſary, becauſe there muſt be more Chyle Conveyed thro' the Latter for the Nouriſhment of the whole Body, than Blood, thro' the Former, Remaining from the Nouriſhment of the Inteſtines only.

Second, In Colour, the Lacteals being White and Clear, and the Meſaraicks of a Dusky and Blackiſh Complexion.

Third, In their Inſertion, the one Terminating in the Common Receptacle, and the other in the Liver.

The Difference betwixt the Lacteals and the Lympheducts.

Betwixt the Lacteals and Lympheducts there is not the ſame Diſtinction, and ſome Queſtion, whether the ſame Veſſels be not in the Meſentery Common Conduits for both Liquors, the Chyle and the *Lympha*; This however is obſerved, that during the Time of Digeſtion, there are no Lymphatick Veſſels to be ſeen in the Meſentery, but it Exhibits an infinite Number of Milky ones; and on the Contrary, after Digeſtion, all the Milky Veins Diſappear, and a prodigious Number of Lymphaticks preſent themſelves to our View. The Lacteals have a pretty many Valves, but not ſo many as the *Ductus Thoracicus*, and which may be Diſcovered the ſame way, as thoſe of the Latter.

Why the Chyle Tends towards the Heart, according to the preſent Anatomiſts.

The Way, which the Chyle takes in it's Paſſage to the Heart, has been hitherto Deſcribed, but what ſhould be the Reaſon or Cauſe of this Motion is to be Inquired; It is thought not to Proceed from the Attraction of the *Lacteæ*, as if they Sucked up the Chyle out of the Guts, for ſuch Elective Attraction has been a long Time Exploded, but the true Reaſon is Imagined to be the Preſſure of the Guts, whereby the Chyle is Squeezed thro' their Spongy Inner Cruſt or Coat into the Mouths of the *Lacteæ*; Which Preſſure Proceeds partly from that undulating Contraction of the Guts, that is Performed by their own Fibres, which one may plainly obſerve in Conies opened Alive, and partly from their being heaved to and again by the Muſcles of the *Abdomen*, and the Diaphragm in Reſpiration; After which the whole Progreſs of the Chyle is ſuppoſed to be made by a Continual Protruſion of it to the Heart; and the Aſcent of it is reckoned to be aſſiſted by a Mixture of the

Lympha with it in the Receptacle and the Duct; not only becauſe the Chyle is thereby Dilated, but more Eſpecially, becauſe a Motion is Impreſſed upon the *Lympha* from the Pulſation of the Heart, whereby it is made to Circulate by the Lymphe-ducts, as well as the Blood by the Veins: This is the Account, which the Anatomiſts give of the Chyle, and the *Lympha*, and the Paſſage of them to the Heart, and of the Ducts, by which they are Conveyed thither; which we ſhall now moreover Explain by our Doctrine of the Expanſive and Contractive Forces.

Why there is a Nervous Duct of the Spinal Marrow Anſwerable to the Alimentary one, and the Aorta, *and how the Meſentery, and it's Veſſels are Formed, as well as the Ribs and other Bones in the Animal Syſtem.*

§. 2. And Firſt it is to be Obſerved, that as there is an Alimentary Duct from the *Oeſophagus* down thro' the whole Canal of the Inteſtines to the *Rectum*, by which an Expanſive Force is conveyed thro' the Body, of which Force our Aliments principally Conſiſt, as likewiſe the *Aorta*, ſo to Balance theſe there is likewiſe a Contractive Force of the Spinal Marrow Propagated from the *Cerebellum*, and the *Medulla Oblongata*, thro' the *Vertebræ* to the *Os Sacrum*; And as the Chyle Paſſes from the Alimentary Duct towards the Center of the Meſentery, ſo from thence a Contractive Force is Diffuſed, namely, from the *Vertebræ* of the Loins, to Meet and Oppoſe, and Counterpoiſe the Expanſive of the Former; the Contractive Force from the Brain, and the Medullary Subſtance Derived from it, Inveſting the Expanſive of the Chyle, and Blood, and *Lympha* with Coats, and Cementing thoſe Coats together with Membranes, which Form the Meſentery; And it is not Improbable, that the Ribs are only Protruſions of the ſame Contractive Force from the Spinal Marrow; a Membrane, a Cartilage, and a Bone differing chiefly in their Degrees of Hardneſs, which ſeems to be Induced upon them from their Lying betwixt the Two Contrary Actions of the Expanſive and Contractive Forces of the Nervous and Sanguineous Syſtems, by which they are Conſtipated and Condenſed in the ſame Manner, as Steel by the Expanſive of the Fire and of the Hammer, and the Contractive of Water and of the Anvil; and the like may be ſaid of the other Bones.

Why the Meſentery is Simple in it's Origin, and Circular in it's Figure, and the Reaſon of of it's Fat, and it's Nerves, and the Plexus's *of Them.*

§. 3. The Meſentery is Plain and Simple in it's Origin at the *Vertebræ*, as the Contractive Force is ſo, but is afterwards Diſplayed in ſeveral Wreaths and Folds, and Enlarged into a Circumference, by it's Exerting it ſelf againſt the Expanſive from the Alimentary Duct, and the Chyle, and Blood, and *Lympha* Diſperſed in the ſaid Meſentery.

It is not above a Span from it's Center, becauſe the Forces on each Hand have that Degree of their Exertion in their mutual Conteſt with each other; and it is nearly Circular for the ſame Reaſon, becauſe Equal Forces, Acting againſt each other, muſt Produce Equal Lines, and being Propagated from the Riſe of the Meſentery, thoſe Lines muſt be Radius's of a Circle Drawn from a Center.

It is Compoſed of Two Common Membranes, which are Continued from a Duplicature of the *Peritonæum*, which has alſo in Part it's Origin from the *Vertebræ* of the Loins; Betwixt theſe Two it has a Proper Membrane, which is Thicker than either of the other, becauſe the Blood-Veſſels, the Chyliferous, and Lymphatick, have their Courſe thro' it, on which Account the Contractive Force is Gathered in Greater Quantity about the Expanſive in thoſe Veſſels, and the Membrane thereby becomes Thicker; And from hence it obtains the Middle Situation; For the Contractive Force Acting againſt the Expanſive, firſt Inveſts the Fluids with Coats, then Strengthens and Unites them by Membranes and Glands, which Intercede the Veſſels; and laſtly, Encompaſſes the Proper Membrane with one on each Side, that it may ſufficiently Encloſe the Expanſive Force, againſt which it Oppoſes it ſelf, by which the Expanſive is Obliged and Determined to a Circulation.

It is ſtuffed with Fat betwixt it's Membranes, which Ariſes, as has been ſaid, from a Mixture of the Expanſive and Contractive in their Mutual Conteſt, but in Lean Perſons, in Human *Embryos*, and in Dogs and Cats, and ſuch like Animals, there is little of it, becauſe the Contractive is ſo far Prevalent over the Expanſive, that there is not a due Mixture of Them; Which is Evident from the Account we gave before of Lean Perſons and of a *Fœtus*; and Dogs and Cats have from their Fierceneſs or the Prevalence of the Nervous Syſtem, and the Defect of the Muſcular and Sanguineous an Exceſs of the Contractive.

The Nerves, as Containing a Contractive Force, diſperſe Themſelves in vaſt Numbers thro' the Meſentery, in order to aſſiſt to this Effect of Forming theſe Membranes by their Fibres every where Detach'd to Encounter the Expanſive of the Blood and Alimentary Fluids, as well as that alſo of the Bile, which here Mixes with them; Hence thoſe Two Notable *Plexus*'s are made, one of which is Compared to the Sun amongſt the Planets, and hence they accompany the Sanguiferous Veſſels in their whole Proceſs, and Climb upon, and Twiſt about Them by their Oppoſition againſt and Counter-Action to Them; And hence laſtly it is not Improbable, that there are other Nerves, according to *Spigelius*, beſides the Meſenterick, which Spring from the *Medulla Spinalis*, between the Firſt, Second, Third, and Fourth *Vertebræ* of the Loins, which Iſſue from thence to Curb and Reſiſt the Expanſive in Conjunction with the Foregoing.

What it's Lympheducts are, and the Lympha *with which they are Repleniſhed.*

§. 4. THE Lympheducts ſeem to carry a Water, which bears the ſame Proportion of Force to the Animal Syſtem, as Common Water does to the Mundane, that is, it is in a kind of Middle Proportion betwixt the Expanſive and Contractive; Common Water is not ſo Contractive, as Salts, Froſt, or Metals, nor ſo Expanſive, as Spirits, Heat, or Fire, but is capable of being eaſily Cemented into Ice, or Reſolved into Vapours, by the Application of one or the other; and conſequently may be Converted in Cold Places, as in Vaults, into a Nutrition for Stones, and in Hotter into one for Plants and Vegetables; Thus likewiſe the Animal *Lympha* appears to be an Intermediate Fluid betwixt the Nervous and Sanguineous Forces, that is, the Contractive and Expanſive ones, and therefore is Expanſive in Compariſon with the Contractive Force, and Contractive, if Compared with the Expanſive; But it is more Spirituous, and has a Greater Expanſive Force than Common Water upon Two Accounts.

FIRST, Becauſe all the Fluid and Solid Aliments we take in, Excepting Water, are furniſh'd with a Moiſture or Watry Humour, but Raiſed into a Degree of the Expanſive by Heat or Fermentation, even before they are Received into the Mouth or Stomach, after which that Spirituous or Expanſive Force is again in ſome Meaſure Increaſed.

SECOND, Becauſe the Contractive Forces of the Body themſelves, as the Nervous Juice, Membranes, Cartilages, and even Bones, are Temper'd with a Greater Degree of the Expanſive, by the Continual Circulation of Warm and Expanſive Fluids amongſt them, than the Contractive Forces in the Mundane Syſtem; and therefore the *Lympha* of the one will be more Spirituous and Expanſive than the mere Water of the other, and this Notion of it will Account for all the Phænomenons of theſe Lymphaticks.

Why the Lymphaticks are Inveſted with a Thinner Coat than the Veins, and the Arteries with a Double, and the Reaſon of their Knots, and their Valves.

§. 5. THEY are Inveſted with a very Thin Membrane, or Coat, whereas the Veins are with a much Thicker, and the Arteries with a Double one; Becauſe the *Lympha* has a much leſs Expanſive Force than the Venal Blood, and ſtill Leſs than the Arterial, and therefore the Contractive Force from the Nervous Fluid is leſs Aſſembled about the Former, than the Two Latter, and a leſs Quantity ſerves to Incloſe, in order to Balance and Poiſe it: They are Long and Hollow like a Vein for the ſame Reaſon, which was given for the Veins being ſo; Becauſe the Expanſive Force being hindred from Dilateing it ſelf by the Contractive, which Inveſts it, muſt Exert it ſelf forwards and Form the Cavity of a Canal: They are Small; Becauſe the Expanſive Force of the *Lympha* is very Minute in Compariſon with the Blood, and therefore Enlarges it ſelf to a ſmaller Compaſs in it's Ducts, than the other; and are Knotty, becauſe the Contractive Force frequently Prevails againſt the Weakneſs of the Expanſive; to which Cauſe likewiſe it's Valves may be Attributed, which are only an Intruſion of the Contractive Force into the very Courſe and Conduit of the Expanſive, and which muſt be owing to the Prevalence of the Former, and to the Inability of the Laſt to Reſiſt it, that is to the Weakneſs of it: Theſe Valves open towards the Common Receptacle, and ſhut the Contrary way; Becauſe tho' the Contractive Force is ſtrong enough to Interrupt the Current of the *Lympha* at certain Intervals, yet the Expanſive Force of the *Lympha* is not ſo Languid, as to be Entirely Obſtructed by it, but by Preſſing forwards ſtill Removes and Opens the Obſtruction; But if it is Endeavoured to be forc'd back again, the Valves cloſe; becauſe ſuch an Impreſſion is Contrary to the Expanſive Force of the *Lympha* Forwards, which therefore becomes Contractive, and joins with the Contractive of the Valves, by which they both unite againſt the Violence Induced upon them; or, which is the ſame in Effect, the Expanſive Force of the *Lympha*, which Exerted it ſelf Forwards, having now a Contrary Determination Impreſt, it's Force is Loſt and Deſtroy'd, and therefore incapable of opening the Valve Backwards, or Surmounting the Contractive Force, which before it was ſufficient to do.

Why the Lymphaticks of the Meſentery have their Origin from the Canal of the Inteſtines.

§. 6. They, according to *Malpighius*, Riſe from Glands, and, according to *Steno*, Riſe from them or are Inſerted in them, but neither of them Determine, what thoſe Glands are, from whence they have their Origin; tho' it ſeems to be Manifeſt, that they Begin, as the Lacteals do, from the Alimentary Duct, or the Canal of the Inteſtines, and which is expreſly Affirmed by other Anatomiſts, which is the Reaſon, that ſometimes we find the very Lacteals filled with *Lympha*, which could not be, if it were not Derived into them from the ſaid Alimentary Duct; Beſides it is Natural for us to Think, that the Primary *Lympha*, before it Arrives at any Glands, is made from the Firſt Concoction and Leaſt Alteration of our Food, and that it is the Moiſture of it Separated from the Chyle, and Elevated into a Small Degree of the Expanſive by it's Paſſage thro' the Stomach to the *Jejunum*.

Why, during Digeſtion, the Lacteals appear in the Meſentery, and afterwards the Lymphaticks.

§. 7. And hence that Remarkable Phænomenon of *Tauvry* Admits of a Solution, that, during Digeſtion, the Lacteals appear in the Meſentery in Great Numbers, after which they Vaniſh, and the Lymphaticks Fill and Riſe in their Stead; Which muſt be owing to the Greater Expanſive Force of the Chyle, and a Leſſer Degree of it in the *Lympha*, by which the one Repells the other and Enters Firſt the Meſaraick Veſſels; and when it has thus opened a Paſſage, to it ſelf, to the Common Receptacle, the *Lympha* is left to Succeed it by a Slower and Heavier Expanſive; And for the ſame Reaſon it continues to Glide into the Common Receptacle, and to Aſcend in the *Ductus Thoracicus*, after the Chyle has Relinquiſh'd it.

Why theſe Lymphaticks Tend from their Firſt Origin to other Glands, and why the Greateſt Gland is in the Center of the Meſentery, and the ſmalleſt in the Coats of the Inteſtines.

§. 8. These Lymphaticks Tend from their Firſt Origin in the Glandules, or Small Knots, of the Inteſtines, which it is Probable are Formed by a Contractive Force to Curb and Reſiſt the Greater Expanſive of the Chyle and the Leſſer of the *Lympha*, to other Glands, which likewiſe are ſeveral Congeries and Aſſemblages of the Contractive Force to oppoſe the Expanſive of the ſame Chyle and *Lympha*, and which are Greater, as we Approach nearer to the Center of the Contractive; and therefore the Greateſt Gland is in the Center of the Meſentery, and Leſs, as we Come nearer to the Center of the Expanſive, and conſequently, the ſmalleſt Glands are in the Coats of the Inteſtines; which alſo furniſhes us with a Reaſon, why the Meſentery is Enlarged from a Center to a Circumference, becauſe at the one the Contractive Force moſt Prevails, and at the other the Expanſive.

Why theſe Lymphaticks are from their Origin diſperſed upon the Surface of the Subſequent Glands, and do not paſs thro' them.

§. 9. Hence alſo it is, that the Chyle and the *Lympha* paſs thro' the ſmall Glands of the Inteſtines, notwithſtanding their Obſtruction, becauſe their Contractive Force is Inconſiderable in Compariſon with the Expanſive of the other; but when the Lymphaticks in their Progreſs towards the Common Receptacle Arrive at any Subſequent Glands, they do not Paſs thro' them, but are Diſperſed on their Surface, becauſe the Contractive Force of the Latter is too Great to be Surmounted by the Former; On the Contrary, the Lacteals paſs thro' the ſame Glands, the Expanſive Force of the Chyle, which they Contain, being Greater than that of the *Lympha*, but yet they are always Diſperſed into ſeveral Small Channels from a Larger Duct, before they enter the Glands, by Reaſon of the ſame Oppoſition from the Contractive Force of them, and from thoſe Small Channels unite again into one Duct, after their Paſſage thro' the Glands, by the Property in Nature before Explained of Similar Forces Aſſembling to each other, by which alſo ſeveral Branches unite into one Trunk before their Entrance into the Glands; Laſtly for the ſame Reaſon, when all the Trunks of the Lacteals Approach to the *Pancreas Aſellii*, or Middle Gland of the Meſentery, moſt of them Enter into it by the ſame Superiority of the Expanſive Force, but ſome are Repelled by the Contractive Force of the Gland, which Force is here the Greateſt, and are made to Climb upon it's Surface; And all of them preſently after unite in the Common Receptacle by the ſame Property, Quality, or Affection in Nature, of Similar Forces Attracting each Other, by which They Aſſemble together, and Coaleſce into one.

How the Chyle and Lympha *are Altered in their Paſſage from the Inteſtines to the*

§. 10. It muſt be farther Obſerved, that in the Paſſage of the Chyle and *Lympha* from the Inteſtines to the Common Receptacle, their Forces are Altered by this Repulſion from the Glands, and their Re-union afterwards, for tho' there do's not ſeem to be any Percolation of the Chyle or *Lympha* thro' them, yet their Expanſive Forces

are

Common Receptacle, not by a Percolation of the Glands, but by a Change of their Forces.

are Changed by the Contractive of the Glands, and very Probably Diminiſhed by them, ſo that Creeping up by the Thoracick Duct to the Subclavian, they do not Enter that Vein in one Large Orifice, but in Six or Seven Little ones, the Expanſive of the Venal Blood in ſome Meaſure Repelling the Chyle and *Lympha*, which is now almoſt of a Contractive Nature, as when it was of a more Expanſive, the Glands, which are of a Contractive, had done; For this Reaſon alſo the *Ductus Thoracicus* is carry'd up on the Side of the Great Artery, the Expanſive of it's Fluids being Weak, and wanting to be Animated and Supported by the Cheriſhing Force of ſo Powerful a Neighbour: And hence likewiſe it was neceſſary, that the Bile, which is Hot and Expanſive, ſhould be conveyed to theſe Parts, to Act againſt and Poiſe the ſtrong Contractive, which was Propagated from the *Vertebræ* of the Loins, and the Center of the Meſentery; with theſe Forces, namely, the Languid Expanſive of the Chyle, the *Lympha*, and the Venal Blood, and the more Exalted of the Bile, the Entrance is made into the Right Ventricle of the Heart, which therefore Mixing with the Blood there, which is ſtill of a more Expanſive Force, muſt Cauſe an High Degree of Accenſion, and Contribute to the Vaſt Pulſation in it, which we ſhall afterwards conſider.

Why the Lacteals and Lymphaticks are either Inſerted into the Common Receptacle, or the Thoracick Duct, or into Veins.

§. 11. THIS alſo gives an Account, why the Lacteals and Lymphaticks are either Inſerted into the Common Receptacle, or the Thoracick Duct, or into Veins; For the Expanſive Force of the Blood in the Arteries is too Great to admit of a Force in the Lacteals and Lymphaticks, which, by the Smallneſs of it's Expanſive, has in Compariſon almoſt the Nature of a Contractive, and the Contractive Force in the Nerves is Repulſive of the Expanſive of the ſame Lymphaticks and Lacteals; On the Contrary, that Lacteals may convey their Fluids into Lacteals, or Lymphaticks into Lymphaticks, is Evident, by that Law of Nature, we before Mentioned, by which Similar Forces Aſſemble to each other; Thus alſo Lymphaticks may Transfer their Juices into Lacteals, and Both their ſeveral Liquids into Veins, becauſe they have all a low Degree of the Expanſive, and nearly Approach to one another in their Diſtinct and Particular Forces.

The Account of the Lympha *before Given, Agrees with the Notions of Anatomiſts, and ſhews why it Turns to a Jelly without Heating it, which Serum will not.*

§. 12. WHAT this *Lympha* is we have already Explained, that it ſeems to be Water Exalted into a ſmall Degree of the Expanſive in the Stomach and Inteſtines, and which well Enough ſuits with the Opinions of *Bartholin*, *Gliſſon*, *Diemerbroeck*, and *Segerus* Concerning it, which were before Recounted; And that by Standing, without Heating it, it Turns to a Jelly, which *Serum* will not do, is owing to the Low Expanſive of the *Lympha*, being ſubdued by the Small Contractive of the Air, from whence it Grows into a Conſiſtence; *Serum* on the Contrary is of too Heavy and Phlegmatick a Nature, as Common Water likewiſe is, to be thus Affected, Conſtipated, or Coagulated by the Gentle Force of the ſame Contractive, which yet ſubmits to a more Violent one, as that of Froſt and Extreme Cold; That is, Common Air has the ſame Influence to Reduce the Animal *Lympha* to a Contractive, which a Frozen one has to Impreſs it on Urine and Common Water; which ſhews the one is a more Fine and Delicate Fluid, and the other a more Lumpiſh and Groſs: As for the Lympheducts, which Paſs from the Liver thro' the Meſentery, 'tis not Impoſſible, but ſome of the Meſaraick Veins may Convey a *Lympha* in them to it, and by an Aſſemblage of *Lympha* from other Parts it may be Remanded back to the Meſentery to Attend and Balance the Expanſive Force in the Bilious Veſſels.

Why the Glands in the Meſentery are Whiter in Young Perſons than in old, and Fewer and Smaller in Men than in Brutes.

§. 13. THE Reaſon of the ſeveral Glands in the Meſentery, and of that in the Center of it, called *Pancreas Aſellii*, we have before Aſſigned: Why they are Whiter in Young Perſons than in Old, Proceeds from the Chyle being ſo, with which they are Tinged, and that, from the Expanſive Force of the Chyle being Greater in the one than the other, as all the Forces of the Animal Syſtem are; Theſe Glands are likewiſe Fewer and Smaller in Men than in Brutes, becauſe upon the Account of the Continual Aliment taken in by the Latter, which is of an Expanſive Force, and a Continual Digeſtion of it in the Stomach and the firſt Inteſtines, the Expanſive Force from the Alimentary Canal is Leſs in Men than in Brutes; and conſequently the Contractive Force from the *Vertebræ* of the Loins, and the Center of the Meſentery, muſt be Greater to Oppoſe and Balance the Expanſive, and therefore the Glands in the Meſentery muſt be more Numerous and Greater in the Latter than in the Former, in Brutes than in Men.

Why all the Venæ Lacteæ *are Inſerted into the* Pancreas Aſellii.

§. 14. All the *Venæ Lacteæ* are Inſerted into the *Pancreas Aſellii*; Becauſe the whole Expanſive Force of the one is Directed againſt and Unites to Oppoſe and Surmount the Contractive of the other, which is there the Greateſt: And when theſe Glands grow Schirrous and Hard, or are Obſtructed, That is, when the Contractive of them is too Great to be overcome by the Expanſive of the Chyle, it cannot be Conveyed into the Blood for a ſupply of it; the Blood cannot be Furniſhed to the ſeveral Parts of the Animal Syſtem for their Nouriſhment, and by conſequence, an Atrophy muſt Enſue, and the Perſon die Tabid; and by a like Obſtruction of the *Lympha*, an *Aſcites* is probably Cauſed.

Why the Common Receptacle is Membranous, and Thicker in Men than in Brutes.

§. 15. The Common Receptacle is Membranous, that is, of a Contractive Force; becauſe the Chyle and *Lympha* are of an Expanſive, which therefore it Surrounds and Incloſes; It is Thicker in Men than in Brutes, but not ſo Capacious, becauſe the Contractive and the Nervous Force is Greater in the Former, and the Alimentary and Expanſive in the Latter.

Why the Meſaraick Veins are Bigger, and the Lacteals more Numerous and Smaller.

§. 16. The Meſaraick Veins are Bigger, and the Lacteals more Numerous and Smaller, not for the Reaſon above Aſſigned, §. 1. ſince the Largeneſs of the one may be Compenſated by the Number of the other, but becauſe the Expanſive Force of the Venal Blood, tho' Leſs than that of the Arterial, is Greater than that of the Chyle; from whence the Cavity of the Meſaraick Veins is Dilated to a Larger Circumference than that of the Lacteals, and the Coats or the Contractive Forces, which Encompaſs them, are Greater and Stronger; The Veins are Fewer, becauſe the Expanſive Force, which they carry, is Stronger and therefore more United, that of the Lacteals Weaker, and therefore more Diſperſed by the Contractive.

Why the Chyle is White and the Blood Red.

§. 17. The Chyle alſo is of a White Colour, and the Blood of a Red, becauſe the Expanſive Force of the Firſt is Leſs, than that of the Laſt; It being known, that Rays of a Red Colour are the Leaſt Refrangible, that is have the Greateſt Expanſive Force, and thoſe of a White one Proceed from a Mixture of all the Different Degrees of the Expanſive Forces, as the Chyle may be juſtly Imagined to do.

That the Motion of the Chyle and Lympha *is not by the Preſſure of the Guts and a Protruſion, but by the Expanſive Force of the Chyle and* Lympha, *Tending towards the Expanſive of the Blood in the Heart.*

§. 18. Lastly, As to the Motion of the Chyle and *Lympha*, it is ſuppoſed to be by a Preſſure of the Guts, and afterwards by a Continual Protruſion of thoſe Fluids to the Heart; Againſt which there is this Objection, that the Contraction or Preſſure of the Guts cannot be ſo Great, as to bring the Sides of them together, without which, it is not to be Conceived, how ſo Thin a Fluid, as the Chyle and *Lympha*, ſhould be Forced into the Small Mouths of the Lacteals of the Meſentery, by a mere Periſtaltick or Vermicular Motion of the Guts, which is all the Contraction, they own or acknowledge: Beſides, afterwards, in the Lymphaticks and Lacteals, theſe Fluids cannot be Promoted or Protruded to the Heart by an Impreſt Force from the Inteſtines, for the Reaſon we have given before, becauſe by a Protruſion only they cannot be Forced back again, which the Tender Valves, in ſuch ſmall Veſſels, would certainly admit of, if there were not ſomething in the Real Forces of the Liquids and Solids, which Contradicted and Oppoſed it.

Farther, Tho' this might be Allowed, and that the Valves opened towards the Common Receptacle, and ſhut the Contrary way, yet it cannot eaſily be Imagined, how the Chyle and *Lympha* ſhould be Thruſt upwards thro' the Thoracick Duct by a Protruſive Force only; Since, according to this Account, the Gravitation of the Fluids backwards might be Superior, or Equal, to any Propulſion of them forwards, from whence there would be an entire Obſtruction to the Circulation of them.

On the Contrary, we ſay, againſt which there are none of theſe Difficulties, that the Expanſive Force of the Chyle and *Lympha* Tends towards the Expanſive Force of the Blood in the Heart, by that Law of Nature, which we have often Mentioned, of Similar Forces Aſſembling to each other; but the Contractive Force from the *Vertebræ* of the Loins coming in to Balance this Expanſive, theſe Fluids do not Proceed immediately to the Heart, but are carry'd thro' the Meſentery, the Receptacle, and Thoracick Duct, as before Explained.

Why the Chyle and *Lympha* do not Tend towards the Liver, which we have ſaid has a Great Degree of the Expanſive, but towards the Heart, is for Two Reaſons.

First, Becauſe the Courſe of both of them is Determined towards the Heart, or the Red Beating Speck in the *Embryo*, before the Liver is Formed, which is not done, till after the Joining of the *Placenta*, or Womb-Liver, to the *Uterus*.

SECOND, Becauſe the Expanſive Force of the Bile is ſo Great, that it Repells the Smaller one of the Chyle and *Lymphæ*, and Urges it towards the Receptacle and Thoracick Duct, and from thence to the Subclavian and the Heart: And this is the Reaſon, wherefore the Chyle cannot be Forced into the Lacteals by a mere Protruſion, according to Dr. *Drake*; Becauſe in a Dead Subject the Expanſive Force of it is Loſt, and the Tendency of it to a Similar Force in the Venal Blood Ceaſes, and cannot be Repaired by any Protruſion.

CHAP. VII.

Concerning the Thorax, *Diaphragm*, Pleura, *and* Mediaſtinum.

An Account of the Thorax, *Diaphragm*, Pleura, *and* Mediaſtinum, *and of the Heart and Lungs by Anatomiſts, and Firſt of the* Thorax *or Breaſt in this Section.* Syllabus Enterologiæ. Prælect. 3. Dr. Gibſon's Anatomy, Chap. 3, 4, 5, &c. to the 14. Book 2. Dr. Keill's Anatomy, Chap. 3. §. 1, 2, 3, &c. to the 6*th*. Dr. Drake's Anthropologia Nova. Chap. 1, 2, 3, &c. Book 2. to Book 3. Blancard's Anatomia Reformata, Cap. 2. to the 10*th*. Tauvry's Rational Anatomy, Chap. 4, 5, &c. to the 8*th*. Alphonſus Borellus de Motu Animalium, Cap. 4, 5, &c. to the 9*th*.

§. 1. THE next Part to the *Abdomen*, which is Examined in an Human Diſſection, is the *Thorax* or Breaſt; Which is Bounded above by the *Claviculæ* or Channel Bones, below by the Diaphragm or Midriff, which ſeparates it from the *Abdomen*, in the Fore-part by the Breaſt-bone and Cartilages, in the Sides by the Ribs, and behind by the *Vertebræ* of the Back; It's Figure is in a Manner Oval, ſomewhat Flat before and behind, whereas in Beaſts it is ſomewhat Sharp; It's proper Containing Parts are either External, as the Breaſts, the Muſcles, and the Bones, or Internal, as the *Pleura*, the *Mediaſtinum*, and Diaphragm.

As to the Breaſts, they have Arteries, Veins, Nerves, and Lymphaticks, in Common with other Parts of the Body, which it is not neceſſary here Particularly to Deſcribe and Diſtinguiſh; only that the Arteries and Veins are Branches of the Subclavian and Intercoſtal, and that the Nerves are from the Vertebral Pairs, and from the Sixth Pair of the Brain; And from the Quantity of Fat in them *Malpighius* Collects there are *Ductus Adipoſi* Diſperſed in their Subſtance; This may be ſaid, that they conſiſt of many Glandulous Bodies of a Different Bigneſs, of which there is one Bigger than the Reſt, juſt under the *Papilla*, or Nipple, which is of an Exquiſite Senſe, Spongy, Covered with a Thin Skin, and full of Little Holes; It is made of Two Orders of Fibres, the Smalleſt make a Fine Net-work within the Larger Spaces of the Net-work of the Larger Fibres; The Spaces betwixt the Glands are filled up with Fat, and there are Abundance of Veſſels that go from one to another, and are all Incloſed by the *Membrana Carnoſa*; Theſe Glands ſeparate the Milk or Chyle from the Blood, Iſſueing out of the Left Ventricle of the Heart, to which the Chyle is not yet Aſſimilated, and which is driven hither along the Thoracick Arteries, unleſs we allow the *Venæ Lacteæ* to come hither, which Opinion is not thought Probable; And in the *Papilla* all the *Tubi Lactiferi* End; The *Areola* is a Small Circle, which Surrounds the *Papilla*, which in Virgins is Pale and Knotty, in thoſe that are with Child, or give Suck, Brown, and in Old Women Black, as the *Papilla* is Red in Virgins, Livid in thoſe that give Suck, and in Old Women Blackiſh; The *Tubuli Lactiferi* are Seven or Eight, or more Small Pipes, which have ſeveral Croſs Canals, by which they Communicate with one another, and they grow Smaller, and Smaller, to their Extremities in the *Papilla*; The Milk is conveyed to them from the Arteries, which Terminate in the Glands, that ſeparate the Chyle from the Blood brought thither, as was before ſaid; which Chyle Runs into the *Tubuli Lactiferi*, upon the Suction of the Child: As to the other External Containing Parts of the Breaſts, namely, the Bones and Muſcles, we ſhall Leave them, with the Anatomiſts, to be Diſcourſed of Diſtinctly and Apart from the Preſent Argument.

That the Milk in the Breaſt is not the Chyle Separated by the Glands of the Mammæ *from the Arterial Blood, but that it is Made and Digeſted in the* Mammæ *by a*

§. 2. THAT which is here to be Conſidered is, what Account can be given of theſe Parts, and the Milk, which they contain, from the Doctrine of the Expanſive and Contractive Forces; Some have Thought, that the Chyle may paſs Directly to the Breaſt by Lacteals from the Stomach, or the Common Receptacle, or the *Ductus Thoracicus*, or from the Womb; but *Diemerbroeck* and Others, who are of this Opinion, are Confuted by *Steno*, Dr. *Wharton*, and Dr. *Needham*; and *Tauvry* has ſhewn, that all the Chyle is Tranſmitted thro' the Subclavian Vein, both by Experiments from Dr. *Lower*, and by his Own, which Confirm them: Anatomiſts therefore have Generally gone into the Sentiments before Explained, that the Chyle is Separated by the Glands, in the *Mamma* or Breaſts, from the Blood conveyed to them by the Mammary or Thoracick Arteries; But how this ſhould be is as little Intelligible as the other; Since the Chyle is ſuppoſed to be Transformed into Blood in the Heart, and how it ſhould be Separated from it by the Glands, when it is no longer in it, but is Changed into another Subſtance, is not to be Conceived; To Say, that the Chyle is not perfectly Aſſimilated into Blood, as Dr. *Gibſon*, and Dr. *Keill*, or, To Say, as *Tauvry*, that the Blood is Compounded of all Particles, of Milky, of Bilious, Urinous, *&c.* is To Say indeed, but not To Prove or Evince the Aſſertion.

Mixture with the Fat and the Nervous Juice.

It is more Probable therefore, that as the Chyle is made in the Stomach, and the Firſt Inteſtines, the Bile in the Liver, the Blood in the Heart, and the Nervous Fluid in the Brain, ſo that the Milk is in the Breaſts, and that it Differs from the Chyle, tho' not much in Colour, yet in Quality and Subſtance; And therefore Dr. *Wharton*'s Argument is of no Force againſt Milk being made from the Blood; Since according to him, if Chyle is Firſt Excocted into Blood, and then made into Chyle or Milk, Nature would Act in Vain and Fruſtrate her own Work: Whereas we Affirm, that Chyle is Effected and Produced from the Digeſtion of the Aliment, but Milk from a Digeſtion of the Blood in the Glands, and the Fat of the Breaſts, and that as the Cauſes, ſo the Fluids Formed and Conſtituted from them, are Different.

Milk and Chyle Different in their Natures.

Thus, tho' our Aliment is Red, or Green, or Yellow, or of any other Colour, it is Reduced to a White Chyle, and is Reſembled in it's Conſiſtence and Colour to Barley-Broth; And by the ſame or the like Operations in the Animal Syſtem, it is not Inconceivable, that Blood may be Reduc'd to a Milk; which is very Different from the Former Fluid, ſince no one ever Imagined, that Water-Gruel could by any Art be Transformed into thoſe Coagulums, of which Milk is known to be Capable by every Days Experience; Beſides that the Conſiſtence of the one is much Greater than that of the other.

This Account of the Milk in ſome Meaſure Confirmed by Malpighius, *and Dr.* Drake.

What Confirms this is, that *Malpighius* likewiſe is of Opinion, that the Buttery Part of the Milk Iſſues from the Fat of the Breaſts, and Dr. *Drake* Aſſerts, that in all Milk the Butter and Oil of it is a Great Part, and that it ſeems to conſiſt of Nothing but Water and Oil united by the Artifice of Nature, perhaps by the Intervention of Salts, with which Milk however Sweet abounds, and he tells us, that by the Mediation of Salts, Water and Oil may be ſo Mixed, as very much to Reſemble Milk, tho' we cannot come up to the Mechaniſm of it, and Make it: In Anſwer to *Malpighius*, Dr. *Gibſon* Objects, in the ſame way as Dr. *Wharton* before, that it is Improbable, that Nature ſhould Separate the Oily or Fatty Particles of the Chyle, to the End they may be Mixt with the ſame again; Which Objection ſuppoſes Two Things, which we Deny; Firſt, That Chyle and Milk are the ſame; And Second, That Fat is made from Chyle; Since we have given an Account how Fat is Formed before, and that it has as much it's Peculiar Production from the Expanſive and Contractive Forces, as Chyle it ſelf has; And we may as juſtly Affirm, that Chyle is made from Fat, as this from the other; Beſides which, there is no one ever Dream'd, that Barley-Broth or Water-Gruel, to which Chyle is Compared, Contained much Oil or Butter in it.

How Milk is made in the Mammæ.

We cannot therefore but Think, that Milk is made by the Expanſive Force of the Blood Mixing with that of the Fat, which is of a Lower Degree, and with the Nervous Juice, which is of a Contractive one; The Contractive Force gives it it's Salts, and the Expanſive it's Sweetneſs and Oil, and there is Apparently a *Lympha* or Water, in which the Red *Globuli* of the Blood Swim, beſides that which is Imported by the Lympheducts obſerved by Dr. *Wharton*; From whence there will be all the Ingredients, which Dr. *Drake* requires to make a Milk of, and theſe are all worked up together by the Animal Force, which he calls, the Artifice of Nature, that is, by theſe Expanſive and Contractive Forces Acting amongſt each other in the Animal Syſtem, which cannot be by any Methods Imitated exactly out of it; As the Animal Oil or *Lympha* cannot be Repreſented by a Vegetative one and common Water, the Two Former having a Peculiar and a Greater Degree of the Expanſive Force than the Latter, and ſuch a Degree, as cannot be Induced upon them, but by the Digeſtions and Circulations, and other Motions, in the Animal Frame.

Dr. Gibſon's *Objection againſt this Explanation of no Force.*

As to the Nervous Juice or Fluid, which we take to be, not any Imaginary *Succus*, but of the ſame Kind and Subſtance with the Brain, Dr. *Wharton* concurrs with us in Attributeing a Share to it in the Formation of Milk, and the Objection which is made againſt it by Dr. *Gibſon*, we ſhall here conſider, namely, the Weakneſs, which it muſt needs Induce upon the Mother, to have ſo much of it Drained away by Suction, which is alſo a Reaſon alledged againſt the Blood's being Exhauſted in the ſame Manner; But is not the Anſwer eaſy, that the ſame Objection would lie againſt the Chyle? Since the Blood and the Nervons Fluid would be Defrauded of ſo much Chyle, as would be Requiſite to ſupply their Syſtems; And it is not Material, whether we take ſuch a certain Quantity of Blood and Spirits away, which will be Replac'd by the ſucceeding Chyle, or whether we take ſuch a certain Quantity of Chyle away, which was by Nature deſtined to Replace the Expence of Them.

Another Objection, which may be Raiſed from the Adipoſe Membrane *and the* Omentum, *Conſidered.*

If to this Doctrine it is Oppoſed, that therefore, if This were True, Milk ſhould be Produced by the *Adipoſe Membrane*, and by the *Omentum*; As to the Firſt, it is a Confirmation of what we have ſaid, that a Kind of Milk is Produced by it; ſince the *Reticulum Mucoſum* or *Parenchyma*, which lies betwixt the *Cutis* and *Cuticula*, is a White Milk or Slime, which is Scraped off from the Inner Side of the *Cuticula*, when Raiſed from the *Cutis*; And as for the Laſt, it has been ſhewn, that the Fat of the *Omentum* is not of an Oily and Expanſive, but in ſome Degree of a Contractive Nature, by it's Brittleneſs, and it's Proneſs to be Congealed; There is yet a Greater Quantity of Milk in the Breaſts than under the *Cuticula*, becauſe there is a Greater Influx of Blood, and a Greater Proportion of Fat in Them.

Why the Breaſts Swell in the Time of Puberty and the Eruption of the Menſes, *and why there are no ſuch Phænomenons in the Male Syſtem, with the Reaſon of Procreation.*
Alphonſus Borellus De Motu Animalium, Cap. 12. Par. 2.

§. 3. Hence alſo the Breaſts Swell about the Time of Puberty, and the Eruption of the *Menſes*; Becauſe we have ſaid the Expanſive and Sanguineous Syſtem Prevails moſt in the Female Sex, and the Nervous and Contractive in Men; and from the *Fœtus* to Puberty there being a Conteſt betwixt the Expanſive and Contractive Forces in Women, the Expanſive now becomes Predominant, and the Blood Diſcharges it ſelf by the Hypogaſtrick Arteries in the Monthly *Profluvia*, and by the Thoracick or Mammary into the Breaſts, where by a Mixture with the Nervous and Contractive Juice it is Elaborated into Fat, as before Explained, in order to Form Milk upon Attracting ſtill a Greater Quantity of Blood that way by Suction; On the Contrary this Phænomenon is not obſervable in Men, there is no Swelling of the Breaſts, nor no Efflux of the *Menſes*, becauſe the Contractive Force is moſt Prevailing in Them; of which Kind is the *Semen*, and which is Acknowledged by *Borellus* to be of the Nature and Subſtance of the Brain, and is Agreeable to what we before Alledged concerning it; and the Diſcharge of it is as much an Indication of the Contractive Force being Superior in Men, as that of the *Menſes* is of a Superior Expanſive in Women: And as we have all along ſhewn, that to Preſerve the Animal Syſtem there muſt be a Kind of *Æquilibrium* betwixt thoſe Two Forces, ſo from hence we are farther Confirmed in that Opinion, becauſe it is neceſſary even to the Procreation of it, that is, a due Mixture of the Expanſive with the Contractive is ſo.

Why the Milk Flows into the Breaſts at certain Times only.

§. 4. But to go on with the Phænomenons of the *Mammæ* or Breaſts; This gives a Solution of the Difficulty, which has been thought Impoſſible to be Explained, namely, why the Milk flows into the Breaſts at certain Times only: Becauſe upon Puberty, and by an Exceſs of the Expanſive Force at that Age, the Blood is Derived into thoſe Parts, where there is the leaſt Obſtruction to it, and conſequently, where there is a Paſſage open to it out of the Body, as by the *Hypogaſtricks* and the *Papillæ*; by the Former of which it is Diſcharged, but meeting with a Nervous or Contractive Force in the Latter, and in the *Mammæ*, together with the Lympheducts, it is ſoftened into Fat and Oil and there Remains; Afterwards upon Suction, there being more Blood drawn that way from the Mammary or Thoracick Arteries, it is Transformed into Milk by a Mixture with the Oil, *Lympha*, and the Nervous Fluid, as we have already ſhewn and Evinced.

Why it is Wanting in Old Perſons, and what Office the Glands Perform in the Mammæ.

§. 5. In Old Women, as the Expanſive Force Abates, and as the *Mammæ* by the Contractive Force, upon a Deficiency of the Expanſive, Harden into Glands and Veſſels, that is, as the Blood, and Oil or Fat, Declines, the Milk is no farther Produced; And if *Diemerbroeck*'s Inſtances are True, which may be much Queſtioned, and may be only the Prate and Tattle of mere Old Women, that Milk has been ſupplied

from them, it muſt be, upon the Account, that their *Mammæ* have ſtill Retained their Fat or Oil, and that there has been a plentiful Influx of Blood into them, which will be found to be as Rare, as Men preſerving their Senſes and Reaſon in their full Force and Vigour to Fourſcore, or an Hundred; Certainly it cannot Proceed from Imagination, becauſe almoſt every Old Man or Old Woman might, upon ſuch a Suppoſition, be Capable of giving Suck to Infants, whereas we have only Two Examples mentioned by him, the one of the Former, and the other of the Latter.

As to the Glands therefore, they are not, as Anatomiſts Imagine, to ſtrain the Chyle from the Blood, but having a Contractive Force, which we Explained before in the Glands of the Meſentery, they Repreſs and Reſtrain the Expanſive of the Blood, and Bring it to a Temper nearer to Milk, which is Perfected, by the Oil and *Lympha* in the Breaſts, into that Balſamick Fluid, which is ſo neceſſary to the Conſervation of the Infant; and which by the Compoſition, we have Named, muſt be very well and rightly Adapted to that Purpoſe; that is, to the Maintaining the Riſing *Æquilibrium* of Forces in the Child, without any Detriment or Prejudice to Them.

Why the Largeſt Gland is ſituate under the Papilla, *and how the* Papilla, *the* Tubuli Lactiferi, *and the* Areola *are Formed.*

§. 6. THIS Account of the Glands gives us alſo a Reaſon, why the Largeſt is ſituate under the *Papilla*, which the Preſent Anatomy cannot do; For if the Glands are to be Conſidered only as Strainers of the Chyle from the Blood, the Largeſt would not be Placed there, where all the Milk in the Breaſts is already made, and where there is no farther occaſion for a Percolation of it; On the other Hand, as we ſhewed in the Meſentery, the Glands muſt be the Greateſt, where the Contractive Force was the Greateſt from the *Vertebra* of the Loins, and where the Expanſive was the Leaſt from the Alimentary Duct, or Canal, ſo here the Gland under the *Papilla* muſt be the Greateſt, becauſe the Contractive Force of the Nervous Juice, and *Lympha*, is the Greateſt by the Extreme Senſibleneſs of thoſe Parts, and the Expanſive Force of the Blood is the Leaſt, as Mixing with the Fat and Oil of the Breaſts, and being oppoſed thro' the Whole of them by thoſe Contractive Forces; and the *Tubuli Lactiferi* grow Smaller and Smaller to their Extremities in the *Papilla* upon the Increaſe of the ſaid Contractive, and Diminution of the ſaid Expanſive Forces; Laſtly, As there is ſome Blood Wreſtles thro' all this Oppoſition, it's Expanſive Force is thereby Augmented and Heightened, as we before ſaid of the Blood, which paſſed thro' the Liquor of the *Amnion* to the Liver of the *Fœtus*; This Expanſive Force therefore Exerts and Diſplays it ſelf beyond the Breaſt, by which the *Papilla* is Formed, and from the Vivacity and Livelineſs of it, the Red Colour Enſues, which upon a Decay of the Expanſive, Firſt Turns to a Livid, and Then to a Blackiſh; The *Areola* ſeems only to be ſo many ſmall Efforts of the Expanſive towards the Raiſing ſeveral other *Papillæ* round the Large one, but the Expanſive being too Weak there is nothing more Produced than certain little White Knots or Protuberances in the Skin, and the Expanſive Force of the Blood, which Thruſt them out, Languiſhing by Age, they become ſomething like the *Papilla*, Firſt Brown and Then Black, as before Recounted.

The Account of the Diaphragm, Pleura, Mediaſtinum, *and* Thymus, *by Anatomiſts.*

See the Places Cited above, §. 1.

The Diaphragm, it's Situation and Subſtance.

§. 7. HAVING laid the Cavity of the *Thorax* Open, the Diaphragm, *Pleura*, *Mediaſtinum*, Heart, and Lungs, Appear.

THE Diaphragm or Midriff Divides the Trunk of the Body into Two Ventricles, the *Abdomen* and *Thorax*; It is Exceeding Nervous, and, thro' the Great Conſent it has with the Brain, when Enflamed or Diſtempered Affects the Mind; It is almoſt Round, Excepting it's Two Appendages, whereby it is Faſtened to the *Vertebræ* of the Back and Loins; It is Seated Tranſverſely or Acroſs the Body, only Slopeing a little Backwards, and is as Broad as the Width of the *Thorax*, for it's Edges are Faſtened to the Lower Part of the *Sternum*, to the Ends of the Loweſt Ribs, and to the Loweſt *Vertebra* of the *Thorax*; It's Subſtance is Muſcular, Conſiſting of Carnous and Tendinous Fibres, like other Muſcles; It has formerly been thought to be only one Continued Muſcle, but *Caſpar Bartholin* Divides it into Two, a Fore and an Hinder, or an Upper and a Lower, as the Diaphragm is ſomething ſlanting Backwards; The Upper Muſcle by one End, *viz.* it's Head, Adheres Circular-wiſe to the Ribs and to the Appendix of the *Sternum*, the Other paſſeth into the Tendon, which makes the Nervous Center of the Diaphragm, and is Spent on or Continued unto the Fleſh of the Lower Muſcle, and ſo the whole Midriff becomes like one Digaſtrick or Double-Belly'd Muſcle; the ſame Author has obſerved, that the Fore-part of the

Upper Muſcle Shoots forth a Tendon to every Baſtard-Rib on each Side the *Sternum*, to which Ribs the Upper Part of the Tranſverſe Muſcles of the Lower Belly alſo Adheres: The Lower Muſcle Springs from the *Vertebræ* of the Loins and Back, and Riſes from thence by Two Appendices, the Right and Left, the Former of which Exceeds the Latter in it's Length, and in the Number of it's Carnous and Tendinous Fibres; The other Extremity of this Muſcle is joined in an Oval to the Center, or Tendinous Part of the Diaphragm, and the Fibres of both the Upper and Lower Muſcles Tend in a Kind of Radius's from their Centers to their Circumferences; The Upper Muſcle is Thin and Broad, the Lower is Thick and has a very Fleſhy Belly.

It's Coats and Perforations. Dr. Gibſon Fig. 2. & 3. Tab. 13. Book 2. Chap. 12.

The Upper Side of the Midriff is Cloathed with the *Pleura*, and it's Lower with the *Peritonæum*, to the Upper Membrane the *Mediaſtinum* and *Pericardium* are Knit, and ſometimes the Loweſt Tips of the Lobes of the Lungs, but this is Preternatural; It is Perforated in it's Tendinous Part by the *Vena Cava* Aſcending from the Liver, and in the Fleſhy Part of it's Lower Muſcle by the Gullet, and Two Stomachick Nerves Springing from the *Par Vagum*, where the Fibres do not Run ſtreight from the Appendices, as before, but bend towards and Encompaſs the Orifice, by the Conſtriction of which the Gullet is exactly Cloſed, ſo that the Continual Motion of the Diaphragm cauſes no Regurgitation of the Contents of the Stomach, nor is the Aſcent of any Vapour Permitted thro' it; The Laſt Perforation is made behind the Appendices by the Deſcent of the *Aorta* along the *Vertebræ* of the Loins and Back, the Thoracick Duct, a Branch of the *Vena Azygos*, and the Intercoſtal Nerve.

It's Arteries, Veins, and Nerves; And the Reaſon of Laughing.

It has Two Arteries called *Phrenicæ* from the Deſcending *Aorta*, and as many Veins from the Aſcending *Cava* in their Paſſage thro' it, with ſome other Peculiar ones, from the *Vena Adipoſa* and *Arteriæ Lumbares*; It's Nerve, which is called the Nerve of the Diaphragm, Ariſes from the Vertebral and Communicates with the Intercoſtal Pair, according to Dr. *Willis*, from whence he Aſſigns a Reaſon of the Great Conſent of the Midriff with the Heart, Brain, and Face, when a Man Laughs; For when the Imagination is Affected with Pleaſure, the Heart would fain Triumph by Throwing off it's Burthen, wherefore, that the Blood may be the Quicklier Emptied out of it's Right Ventricle into the Lungs, and conſequently out of the Left into the *Aorta*, the Diaphragm, being Inſtigated by the Nerves from the Intercoſtal, is drawn upwards with a more Rapid Syſtole, and often Repeating it's Jumps, bears up the Lungs and cauſes them with more Quickneſs and Frequency to Diſcharge the Air and Blood, but the ſame Intercoſtal Nerve, which Communicates below with the Nerve of the Diaphragm, is Continued above with the Maxillar Nerves, and therefore, when a Cackling is begun in the Breaſt, the Geſtures of the Mouth and Face anſwer thereto; and when the Diaphragm is wounded in it's Nervous Part, the Muſcles of the Face ſuffer Convulſions and an Involuntary Laughter, or the *Riſus Sardonius*, is Cauſed.

It's Uſe.

The Uſe of the Diaphragm is, Firſt, To Divide the *Thorax* from the *Abdomen*, that Noiſome and Impure Vapours may not Aſcend from the more Ignoble Parts, as the Guts, to offend the more Noble, as the Heart; Second, To help the Muſcles of the *Abdomen* in Excluding the Excrements and, in Women, the *Fœtus*, and to Preſs the Stomach and Inteſtines for the Diſtribution of the Chyle; Third, To aſſiſt Reſpiration, which is ſuppoſed to be Performed in the following Manner: The Diaphragm from the *Vertebræ* to the Circumference, according to *Steno* and *Bartholin*, is Convex towards the *Thorax*, and Concave to the *Abdomen*, whoſe Firſt Motion is downwards, ſo that from a Convex Laxity it is Depreſs'd to a Plane Surface, as *Bartholin* Teaches, without being Extended, as *Steno* Suggeſts, or Thruſt into the *Abdomen*, as *Diemerbroeck*; This Depreſſion of the Diaphragm to a Plane Surface, by which it's Circumference is Extended, muſt of Courſe Elevate the Sides of the *Thorax*, which *Diemerbroeck's* Protruſion of it into the *Abdomen* could not do, and yet this is what we Experience. The Cavity of the *Thorax* being thus Enlarged, the Air by it's Preſſure or Elaſticity Iſſues in at the *Trachea*, *Aſpera Arteria*, or Wind-Pipe, and the *Bronchus*, which is the Lower Part of it, and immediately Poſſeſſes all the *Bronchia*, or Branches of the *Bronchus*, and *Veſiculæ* of the Lungs, and Puffs them up and Inflates them, by which means Inſpiration is Effected; On the Contrary, the Diaphragm now Returning to it's Former Convex Situation, and Moving upwards into the *Thorax*, it's Sides fall towards each other, whereby it's Cavity is Diminiſhed, and by this Compreſſion of the *Thorax*, and the Contraction of the Muſcular Fibres of the *Veſiculæ*, and of the Inner Coat of the *Trachea* and it's *Bronchia*, the Air is Expelled from the Lungs by the ſame way, by which it Entered, which is the Account given of Expiration; and thus, Inſpiration and Expiration ſucceeding each other Alternately, Reſpiration is Cauſed.

THE Motion of the Midriff is thought to be Mixed, but rather Animal and Voluntary, than Natural and Neceſſary, becauſe, tho' it Moves in our Sleep, yet, when we are Awake, we can Stop, Slacken, or Haſten it's Motion.

The Pleura, *it's Membranes, Perforations, Arteries, Veins, and Nerves.*

THE *Pleura* is a Double Membrane, which Covers all the Cavity of the *Thorax*, and is White, Thin, and Hard, Reſembling the *Peritonæum*, the Inner Membrane, or that next the *Thorax*, is the Thickeſt; 'Tis ſmooth on it's Inſide, and bedew'd with a Wateriſh Humour, Proceeding probably from Vapours Raiſed from the Blood, and Condenſed by the Comparative Coldneſs of this Membrane, but the Outſide, which is fixed to the *Perioſteum* of the Ribs, is Thinner and Rough; It ſends out from it's Inſide certain Nervous Fibres even in Healthful Perſons, which are Inſerted into the Inveſting Membrane of the Lungs, and Hinder the Aſcent and Deſcent of them in Reſpiration, without any Great Injury to their Breathing, tho' ſometimes, when they tie the Lungs too Cloſe, they cauſe a Continual and Incurable *Dyſpnœa*; It's Perforations below have been already mentioned, thoſe above are for the *Vena Cava* Deſcending, and the *Aorta* Aſcending, the *Gula*, the Rough Artery, Lacteals, Lympheducts, and Nerves; It Ariſes from the Membranes, which Inveſt the *Medulla Spinalis*, and from the *Vertebræ* of the Back, from whence it comes forward on each Hand by the Sides to the *Sternum*, or Breaſt-Bone, under which the Membranes of each Side are joined together, and ſo becoming Double, it goes back again ſtreight from the Middle of the Breaſt to the Back, Dividing the Cavity of the *Thorax* into Two Parts, and one Lobe of Lungs from the other, and is called the *Mediaſtinum*; It has Veins and Arteries from the Superior Intercoſtal Branches, and they are ſaid to Run between the Two Membranes of the *Pleura*, betwixt which, when any Matter Impoſthumates, from whence an Inflammation is Cauſed, a Pleuriſy is ſuppoſed to be Produced; It hath Nerves from Twelve Vertebral Pair, namely, from all the Pairs of the *Thorax*, for from betwixt each of the Twelve *Vertebræ* of the Back there Springs a Pair of Nerves.

The Mediaſtinum, *it's Subſtance, Cavities, and Uſes.*

THE *Mediaſtinum* is Formed by a Continuation of the *Pleura*, as Above, and conſequently conſiſts of Four Membranes, being a Duplicature of the *Pleura*, which conſiſts of Two; As it Tends from the *Sternum*, where they are ſtrictly United, the Duplicated Membranes are Sever'd, ſo as to Contain the Heart with it's *Pericardium* in the Cavity, which Intervenes their Separation; After which they again Unite as Cloſe, as before, but preſently Part, to Form as Long, tho' a Narrower, Cavity for the *Oeſophagus*, or Gullet, the *Vena Cava*, and Stomachick Nerves to Deſcend by; Where it is Parted, it is Thinner and Softer than the *Pleura*; The Outſide towards the Lungs is Smooth, but the Inner is Rough, by Reaſon of the Fibres, whereby in ſome Places it adheres to the *Pericardium*, and there is Fat diſperſed in it, eſpecially about it's Veſſels; It has Veins, Arteries, and Nerves, and ſome Lympheducts, as other Parts, and it's Chief Uſes are, To divide the Lungs, ſo that if one Part is Wounded, the other may be Secure, To keep the Heart from Falling upon the Back, or Breaſt-Bone, or the Ribs upon our Bending our ſelves Backwards, Forwards or on one Side, To give a Paſſage to Veſſels, and ſupport the Diaphragm againſt the Weight of the Stomach and Liver, which hang by it.

The Thymus, *it's Subſtance and ſuppoſed Uſe.*

THE *Thymus* is a Glandulous Body, ſituate in the Upper Part of the *Mediaſtinum* under the *Claviculæ*, it is Whitiſh, Soft, and Spongy, and Larger in Children and Women, than in Men; In Infants it conſiſts of Three Glands, and is ſomething like the Sweet-Bread, but in Adult Perſons it Drys and Contracts up into one Subſtance; It has no Proper Duct, whereby any Thing is conveyed into any Peculiar Cavity, and therefore is Eſteemed in the Number of Conglobate Glands, tho' Dr. *Drake* makes it a Conglomerate one; The Jugular Veins and Arteries paſs thro' it, as they go to the Neck; In Children it has Liquor like Chyle in it, and it's Nerves and Lympheducts are Acknowledged; The Uſe of it is ſcarcely Known, and only Gueſs'd at by Anatomiſts, the Later think it is a kind of *Diverticulum* to the Chyle in the Thoracick Duct, when over charged in Children, and that it conveys a *Lympha* from the Adjacent Parts to the ſaid Duct; It having no Valves, for if Wax or a Liquid is Injected into the *Ductus Thoracicus*, it will paſs into the Lympheducts of the *Thymus*: We ſhall now, as Uſual, Examine theſe Phænomenons of the Animal Syſtem by the Doctrine of the Expanſive and Contractive Forces.

How the Diaphragm Separates the Thorax *from the* Abdomen; *how it is Produced, and why it is Slanting, and when Inflamed ſtrongly affects the Mind.*

§. 8. AND Firſt, the Diaphragm Separates the *Thorax* from the *Abdomen* by the Exertion of the Expanſive and Contractive Forces athwart the Body, which could not be done in any other Place of the *Thorax*, or the *Abdomen*, they being both already poſſeſſed by the Lungs and Heart, and by the Stomach, Liver, and Inteſtines, which as we have ſhewn are Primarily Formed, Excepting the Lungs, which will afterwards be Proved; In this vacant Space therefore the Contractive Force of the Nervous Fluid from the Spine Advances, which is Confirmed by Anatomiſts, who acknowledge it's Riſe to be in Two Nervous Appendices Produced from the *Vertebræ* of the Back and Loins, that it is Derived from the Membrane, which Inveſts the *Medulla Spinalis*, and the like; And hence it is, that the Tendinous Fibres, of which it is Compoſed, are Propagated, as a kind of Radius's from the ſaid *Vertebræ*, as a Center; But whilſt this is doing, the Expanſive Force of the Blood from the Deſcending *Aorta* Exerts it ſelf in the Phrenick Arteries, to whoſe Aſſiſtance likewiſe the Lumbar Arteries Arrive, in order to Balance the Contractive Force of the Nervous Fluid from the Spine, by which it's Carnous or Fleſhy Fibres are made, being Conſtipated by the ſaid Contractive Force from Blood into Fleſh; To which the Nerve of the Diaphragm alſo Contributes: The Diaphragm is alſo Slanting, being Lower at it's Riſe in the *Vertebræ*, or in it's Nervous and Contractive Part, and Higher at it's Ending in the *Sternum* and Ribs, or in it's Carnous and Expanſive, becauſe Naturally the Contractive, as it Tends to a Center in it's Force, Deſcends likewiſe towards the Earth, but the Expanſive, Dilateing it ſelf from a Center, Riſes and is Elevated from it: Nor is it any wonder, that ſo Nervous a Membrane, which is immediately Derived from the Spinal Marrow ſhould, when Enflamed or Diſtempered, ſo ſtrongly Affect the Mind, whither all Nervous Senſations are Ultimately Referred.

Why the Diaphragm is a Digaſtrick Muſcle by the Intervention of the Nervous Center, and why it is Convex to the Thorax, *and Concave to the* Abdomen, *as alſo, why the Lower Muſcle is Thicker and more Fleſhy than the Upper,* &c.

§. 9. THE Reaſon, why this Muſcle of the Diaphragm, which otherwiſe would be but one, is Divided into Two by the Intervention of the Nervous Center, ſeems to be the Paſſage of the *Vena Cava* Aſcending from the Liver, which, Containing the Expanſive Force of the Blood, Heats the Parts about it, to Balance which therefore the Contractive Force of the Nervous Fluid Aſſembles to it, and Conſtitutes that Part, which is called the Tendinous, juſt as about the *Aorta* the ſame is done by the Appendices from the *Vertebræ*; On the other Hand, the Expanſive Force of the Aliment, which is carry'd thro' the *Oeſophagus*, is Small and Gentle in Compariſon of that of the Blood, and therefore is not Encloſed with ſuch a Degree of the Contractive Force, but yet the Tendinous Fibres Bend towards it, and more nearly Encompaſs it, and Leave their Rectilineal Progreſs in order to Counter-Poiſe it: And for the ſame Reaſon the Diaphragm is Convex towards the *Thorax* and the Heart, and Concave to the Guts and *Abdomen*, the Contractive bending towards the Expanſive in this Caſe likewiſe: The Lower Muſcle of the Diaphragm is alſo more Thick and Fleſhy, and the Upper Thinner, becauſe the Contractive Force at the *Vertebræ* or Origin of the Former is Greater than that of the Tendinous Part of the Latter; and conſequently, the Expanſive Force of the Fleſhy Fibres muſt be Greater and Stronger to Balance the one than the other: The Midriff Adheres Cloſe to the *Sternum* and Ribs on each Side, not by the Expanſive Force of the Fleſhy Fibres, but by the Contractive of the Nervous and Tendinous ones; for, having now made it's way thro' the Expanſive, it more ſtrongly Cements and Unites to the *Perioſteum*, which is of the ſame Nervous and Contractive Force with it; And this is the Reaſon that *Bartholin* Affirms, that the Upper Muſcle Shoots forth a Tendon to every Baſtard-Rib on each Side the *Sternum*; The Upper Side of the Diaphragm is Lined by the *Pleura*, and the Lower by the *Peritonæum*, which are more Fleſhy Membranes, that is, have a Greater Expanſive Force, and are made by it to Encompaſs and Confine the Contractive of the other, that it ſhould not be too Prevailing.

The Phænomenon of Laughing not Accounted for by Anatomiſts, and which Receives a Solution from the foregoing Principles.

§. 10. As to Laughing, there is an eaſy Account given of it from theſe Principles, without ſuppoſing that Communication of the Intercoſtal Nerve with the Nerve of the Diaphragm below and the Maxillar above, and the Heart's Endeavouring to throw off it's Load, according to Dr. *Willis*; For what? Theſe Nerves do not only Communicate with each other, but there is a Connexion almoſt betwixt all the Nerves of the Body, as may be ſeen in the Syſtem of them, Expreſs'd Tab. 16. Appendix to Vol. 1. of Dr. *Drake*'s *Anthropologia*, and in Dr. *Willis*'s *Anatomy of the Brain*, Tabb. 9, & 11; And it is not Probable, that the Communication here mentioned ſhould Produce ſuch Particular and Singular Effects in the Parts ſpecified in Diſtinction from the Reſt; And why, when the Imagination is Pleaſed, the Heart ſhould Endeavour to throw off it's Burden, is Unexplained, nor is there any Natural Dependency ſhewn of the one upon the other; Beſides the *Cachinnus*, or Noiſe, occaſioned by Laughing, cannot be owing to the Quick Expulſion of the Air from the Lungs barely, for a Quicker or Shorter Inſpiration or Expiration can no more Produce ſuch a kind of a Sound, than our Quick or Short Breathing can produce a Note, or a Modulation of the Voice; On the other Hand, Joy, Pleaſure, Delight, and Satisfaction, are Affections in the Mind of an Expanſive Force, and are Raiſed in it by ſome Expanſive Force in it ſelf, or which is External to it; Thus Wines and Spirituous Liquors, and Wit, which conſiſts in a Velocity, and a Diſſolution or Diſſipation, or Airyneſs, of our Ideas, are Evidently of an Expanſive Nature, and occaſion Mirth, and Laughter, and Jollity, and as Similar Forces produce Similar, Mirth and Laughter likewiſe muſt be of an Expanſive Nature; And from hence it comes to paſs, that as ſoon as the Mind is thus Affected, it Communicates it's Expanſive Force to the Nervous Syſtem, which is of a Contractive, and which Reſults and Rebounds upon the Impreſſion, and Exerts it ſelf in Leaping, Jumping, Danceing, Laughing, and the Like; in the ſame Manner, as the String of an Harp, which is of a Contractive Nature, is Raiſed into Vibrations by Percuſſion, which is of an Expanſive, and in the ſame Manner, as we have ſhewn all Motions are Produced and Continued by an Oppoſition of the Expanſive and Contractive; which Solution, if True, is a plain Conviction of the Diſtinction of the Mind from the Body, and that it is not the Intercoſtal or Diaphragmatick Nerve, which is the main Inſtrument of Laughing, but the whole Nervous Syſtem; and which is the more Confirmed from hence, that Men do not in that Action ſhake their Maxillar Muſcles and their Diaphragm only, but their Sides and their whole Body.

The Cachinnus *from hence Explained.*

§. 11. As to the *Cachinnus* in Particular, or the Noiſe made in Laughing, it is a Quick Return of the Voice from the Quick Vibrations of the Nervous Syſtem, Part of which Acts upon the Lungs, but the Voice it ſelf is formed, as all other Modulations of it, by the Intervention of the *Aſpera Arteria*, and the Palate; an Explanation of which comes under the Doctrine of Sounds, which, as we have before ſaid, always Ariſe from the Reſiſtance of the Contractive to the Expanſive, which is here Communicated from the Mind to the Nervous Syſtem, and from thence to the Lungs and Air Included, and is Reſiſted by the Contractive of the Rough Artery, Palate, and Elaſticity of the External Air.

How Tears are Cauſed, Agreeable to the ſame Principles.

§. 12. This Account is ſtill farther Evinced from Conſidering, what Grief and Sorrow is, and how Tears are cauſed; for ſince theſe Affections are the Reverſe of the Former, if it is True, that they Proceeded from an Expanſive Force in the Mind, Theſe muſt from a Contractive, which it is Plain they do; For Afflictions have a Natural Tendency to make Men Wiſe and Judicious, and Judgment conſiſts in the Gravity, Cloſeneſs, and Connexion of our Ideas, which are manifeſtly of a Contractive Nature; When therefore the Mind is in a State of Grief, which always makes us Conſiderate and Thoughtful, it has a Contractive Force Impreſs'd upon it; Thus alſo, if there is a Melancholy, or Languor in the Blood, which muſt be owing to a Contractive Power, the ſame State is Induced upon the Mind, and it is Inclined to Grieve and to be Sad; This Contractive Force in the Mind, Imparting it ſelf to the Nervous Syſtem, has alſo quite Contrary Effects from what were before Produced, as it ought to have, for now the Nervous Syſtem does not Reſiſt and Rebound againſt the Incurring Expanſive of the Mind, but Submits to and Complys with the Contractive of it, the Forces being now of the ſame Nature; Hence it Contracts it ſelf, Draws it ſelf Inwards, and Retires within the Sphere of it's Proper Activity; Conſequently, we find the Body in a Reſerved and Sedentary Poſture, the Head Drooping, the Legs Acroſs, and the Arms Claſped within each other, which are all ſo many Indications of a Contractive Force Prevailing, and Evident Marks and Proofs of it, as they are Contrary to Leaping, Jumping, Dancing, *&c.* The Tears alſo fall on ſuch Occaſions, becauſe the Nervous Syſtem, and with it the Brain, being Contracted, the *Lympha*, which always ſtands in the Ventricles of it, is Preſs'd and Squeezed from thence, and Carry'd thro' the *Foramen Lachrymale*, ſituate at the Inner *Canthus*, or Corner of the Eye; to which Opinion, tho' he Rejects many others, *Diemerbroeck* alſo is willing to Subſcribe.

The Account above not Contradicted, by the Riſus Sardonius.

THE *Riſus Sardonius* does not Contradict the Solution before Given, ſince where ſo Nervous a Part as the Diaphragm is Wounded, it muſt neceſſarily Affect in a ſenſible Manner the whole Nervous Syſtem, and therefore the Muſcles of the Face, and the Maxillar Nerves Inſerted into Them.

The Diaphragm of little or no Uſe to Reſpiration.

§. 13. AMONGST the uſes of the Diaphragm the Principal is ſaid to be, that of Aſſiſting Reſpiration, whereas we have ſhewn how it comes to be Formed, and that in the Formation there does not ſeem to be any ſuch Deſign or Intention; Nor does the Account Propoſed to us of Reſpiration appear to be True; In order to which it is Preſumed, that the Firſt Motion of the Diaphragm is Downwards, by which the Cavity of the *Thorax* is Enlarged, and the Air thereby Ruſhes into the Lungs in Inſpiration; But which way is this Motion downwards Performed? Not by the Incurſion of the Air, for the Cavity is originally Enlarged before ſuch Incurſion; Not by the Contraction of the Diaphragm, as a Muſcle, becauſe that would draw the Sides of the *Thorax* together, and diminiſh it's Cavity, whereas in Inſpiration they are Raiſed and Elevated, and the Cavity is Widened and Increas'd; Not by the Diſtenſion or Dilatation of it, becauſe that is not the Proper Action of a Muſcle, and only is ſubſequent upon the Contraction of it, and therefore it's Firſt Motion cannot be Downwards; But if the Firſt Motion is Upwards, there being no Air yet Inſpired, the Diaphragm will only Preſs out what Air Reſides in the Lungs before Inſpiration, and upon it's Moving Downwards, ſuch Air will be Replaced, which does not come up to the Phænomenon, as it is Propoſed, of Inſpiration and Expiration, which is here Endeavoured to be Explained; Beſides it is manifeſt, that it is but little Air, that we Inſpire and Expire at once, ſo that there does not ſeem to be any occaſion for the Enlargement of the Cavity of the *Thorax* by the Methods Alledged, that is, by the Deſcent of the Diaphragm, and Leaving a Room or Space for the Lungs to Swell in from the Incurring Air; Nor, which is Material in the Preſent Account, is it really Proved, or can it be, that the Diaphragm does Aſcend and Deſcend; Since another Motion may be Aſſigned to it, which is more Probable, and will Equally Anſwer the Particulars we obſerve of it.

How Reſpiration is Performed, and what is the Real Action of the Diaphragm as well as all other Muſcles, and how Accounted for.

§. 14. CONSIDERING therefore what foregoes, it is more Conſiſtent with Reaſon to Think, that Reſpiration is Performed in another, that is, in a ſimpler Manner, namely, not by the Local Motion of the Diaphragm, the other Muſcles of the *Thorax* we at preſent omit, which yet have their Share in this Action, but by the bare Diſtenſion of it from the Expanſive Force of the Fleſhy Fibres, and the Conſtriction of it from the Contractive of the Tendinous; The Contractive Force of the Latter is allowed by all Anatomiſts, and we only beg the Favour to Introduce the Expanſive of the Former, as Equally Natural and Proper to the Action of a Muſcle, with it's Contraction; And from whence Muſcular Motion in General may be Explained.

Why the Action of the Thorax *and Diaphragm is to and from the* Vertebræ, *and not upwards and downwards.*

WE have already ſhewn, that the Nervous or Tendinous Fibres of the Diaphragm Proceed from the *Vertebræ* towards the *Sternum*, and the Ribs on each ſide it; and therefore the Contractive Force of theſe Fibres will draw the Ribs and *Sternum* towards the *Vertebræ*, and the Expanſive Force of the Carnous, Acting againſt and in Oppoſition to the Former, will Protrude the ſaid Ribs and *Sternum* from the ſame *Vertebræ*; which, if any one will Reflect and Look upon himſelf, when he Breaths, he will find to be the Real Action of the *Thorax*; This likewiſe Explains, why the Ribs on one Side do not in Reſpiration Approach to, or Recede from thoſe on the other, but are carry'd Jointly to and from the *Vertebræ*.

On the other Hand, if we ſuppoſe the Diaphragm to be Moved upwards and downwards in the *Thorax*, in the Firſt Caſe, the Ribs ought to come Nearer to each other, as well as to the *Vertebræ*, and in the Laſt, to Retire from each other; and the Conſtriction and Dilatation of the *Thorax* would be Circular, and not from the *Sternum* to the *Vertebræ*, contrary to Fact and Experience; This alſo Informs us, how Reſpiration may be Perfect, tho' the loweſt Tips of the Lobes of the Lungs ſhould Adhere to the Midriff, becauſe they may eaſily follow the Motion of the Diaphragm backwards and forwards from the *Vertebræ* to the *Sternum*, but not ſo well it's Motion downwards without ſome remarkable Impediment to it.

For which Cauſe the Nervous Fibres, which are ſent out from the *Pleura*, and are Inſerted into the Inveſting Membrane of the Lungs, ſometimes cauſe an Incurable *Dyſpnœa*, which is not ſo readily Conceived, if the Diaphragm is Moved upwards and downwards, as if the Tips of the Lobes Adhere to it, whilſt it is Moved backwards and forwards, for in ſuch a Circumſtance, the Nervous Fibres would very much obſtruct the Motion; Laſtly, This Gentle Conſtriction and Expanſion of the Diaphragm much better Agrees with the ſmall Influx and Reflux of Air, which we find in Breathing, than the Turbulent Ruſhing in and Expulſion of it, which the other Doctrine ſeems to Patronize and Eſpouſe by Enlargeing and Contracting the Cavity of the *Thorax*.

The Queſtion Determined, whether the Motion of the Diaphragm is Natural and Neceſſary, or Animal and Voluntary.

§. 15. The laſt Queſtion concerning the Diaphragm, is, whether the Motion, which belongs to it, is Natural and Neceſſary, or Animal and Voluntary, or whether it is a Mixture of both; To which we Anſwer, that in the Human Frame, which we now Conſider, there is no Diſtinction betwixt Natural and Animal, or betwixt Neceſſary and Voluntary, and therefore the Queſtion ceaſes; For the Natural Motion in it is the Animal, and the Neceſſary is the Voluntary, ſince there can be no Motion, which is not Animated, and no Animation, which is not with the Concurrence of the Mind, and no Concurrence of the Mind without the Conſent of the Will, that is, every Action, as it is an Animal one, is ultimately a Voluntary one, as Volition is Inſeparable from Thinking.

Thus Sitting ſtill is as Voluntary an Action as Walking, Sleeping as Wakeing, and the Motion of the Diaphragm as the Reſt of it, for ſince we can Stop, Slacken, or Accelerate it's Motion by the Will, it muſt be by the Will that it is Perpetuated and Continued; Muſcular Motion is confeſs'd to be Performed by the Will, which alſo is an Animal one, and therefore the Neceſſary Motion of a Muſcle is a Voluntary one; The Circulation of the Blood, which, if any other, is a Neceſſary Motion, is yet a Voluntary one, both as it is a Muſcular, and as the Heart it ſelf is a Muſcle; and as we can obſtruct it by Coughing or Straining, and by a Voluntary Expulſion of the Air from the Lungs, or permit it to Flow thro' them at our Pleaſure: Nay, Theſe very Expanſive and Contractive Forces, which we have been Explaining, and which ſeem to be as Neceſſary in their Laws and Actions, as any Thing in our Syſtem, could not obtain their Effect without an Animation, that is, without a Mind Endued with, and Exerting, it's Faculties, One of which is Volition; of which Opinion, I alſo, ſince my Writing of This, find *Borellus* to have been.

Borellus De Motu Animalium, Prop. 80. Cap. 6. Par. 2.

How the Pleura, Mediaſtinum, *and* Thymus, *are Formed from the ſame Principles.*

§. 16. The *Pleura* likewiſe, as well as the Diaphragm, is formed by a Contractive Force from the *Medulla Spinalis* and the *Vertebræ* of the Back, with which the Expanſive of the Blood Mixing from Veins and Arteries of the Superior Intercoſtal Branches, the Membrane is made; The Contractive Force is farther Strengthened by Twelve Vertebral Pair of Nerves, which will require an Addition of the Expanſive to Balance it; The Expanſive and Contractive being thus Increas'd, as alſo the Latter being Stronger from being nearer the Brain the Source and Fountain of it, which again is to be Balanced by an Expanſive, when they arrive at the *Sternum*, their Forces are ſtill Vigorous and Active, and ſince they Meet each other there in oppoſite Directions, and cannot Proceed forwards, 'tis neceſſary they ſhould Cling faſt together, and at the ſame Time Preſs jointly backwards in a ſtrait Line from the *Sternum* to the *Vertebræ*, by which the *Mediaſtinum* is Conſtituted and Framed: Which Forces muſt yet give way to the Expanſive of the Heart, and therefore Separate upon their Approach to it, but Unite again afterwards, till they Separate a Second Time for the Expanſive in the *Oeſophagus* and *Vena Cava*; And upon theſe Separations, the *Mediaſtinum* is Softer and Thinner than the *Pleura*, becauſe the Expanſive Forces, which Divide it, Diminiſh the Contractive; The Contractive alſo takes it's Courſe from it's Riſe in the *Vertebra* along the Ribs, which are of a Contractive Nature, becauſe Similar Forces, according to the General Law we have Mentioned, Tend to each other, and the Expanſive follows the ſame Track in order to Counter-poiſe it; The *Pleura* is Whitiſh from the Contractive Force.

THE *Thymus* is Formed from the Contractive Force of it's Nerves and Lympheducts, and from the Expanſive of the Jugular Veins and Arteries; It ſeems to be of little uſe, and only the Natural Product of the Concourſe of thoſe Forces; It is Larger in Children and Women than in Men, becauſe the Expanſive Force is Greater in Them, which Diſtends and Swells it, and for the ſame Reaſon it is Divided into Three, ſince it belongs to the Expanſive Force to Separate and Divide as well as Diſtend; But in Men whoſe Contractive Force is Greater, it is Leſs, and Compinged into One; In Children, Chyle may ſupply the Place of the Venal Blood, and therefore is many Times found in it.

CHAP. VIII.

Concerning the Heart, and it's Pericardium, *the* Aorta *and* Cava, *the* Arteria *and* Vena Pulmonaris, *and Circulation of the Blood.*

An Account of the Heart and it's Pericardium *with the* Aorta *and* Cava, *the* Arteria *and* Vena Pulmonaris, *and Circulation of the Blood, by Anatomiſts.*
See the Places Cited Above, Chap. 7. §. 1.
The Heart, it's Situation, Subſtance, Fibres, Nerves, Arteries and Veins.

§. 1. THE Next Parts, which we are to conſider in the Human Syſtem, are the Heart and it's *Pericardium*, with the *Aorta* and Circulation of the Blood: The Heart is the Source of Vital Heat, and the Principal Bowel of the Body, which no Perfect Animal wants, nor can long ſurvive it's Wounds; It is ſituate in the Middle of the Breaſt, Encompaſs'd with the *Pericardium* and *Mediaſtinum*, and it's Lower Tip or *Mucro* Inclines a little to the Left Side; It hangs Looſe in it's *Capſula* or Caſe, only ſuſpended by the Veſſels, that go in and out of it's upper Part or Baſis, to which the *Pericardium* Adheres; In Beaſts, that Feed upon Graſs, it is near the Middle of the whole Body, from the Head to the Tail, but in Men, and moſt Carnivorous Animals, whoſe Necks are Shorter, it is nearer to the Head; It has a Firm, Thick, and Denſe Subſtance, Thinner, and Softer in the Right Side, Thicker, and more Denſe in the Left, but moſt Compact and Hard at it's Tip, only on the Left Side of the Tip it is Thin, as Conſiſting moſtly of the Concourſe of the Inner and Outer Membrane; It's *Parenchyma* is made up chiefly of Muſcular Fibres, ſo that the Heart it ſelf may be Eſteemed a Muſcle.

THE Fibres are of Three Kinds; FIRST, The outermoſt, which Run in ſtrait Lines from the Apex to the Baſis, or which Run, tho' not quite from the Apex, yet Parallel to Them which do.

SECOND, Thoſe which lie next under the Former, and Aſcending obliquely from the Left Side towards the Right Terminate in the ſame Baſis, Imitating a Snail-Shell, or Screw, by their Spiral Circuit.

THIRD, The Inmoſt, which are alſo oblique, but Run a contrary Courſe to the Former, Ariſing from the Right Side of the Heart, and from thence Aſcending Spiral-Wiſe towards the Left, when, having Embraced each Ventricle of the Heart, they Terminate in the Baſis on the Left Side.

THE Fibres of the Left Ventricle differ not from thoſe of the Right as to Kind, only they are conſiderably Stronger, and all of them are Inſerted into a Tendon, that is ſpread over it's Baſis under the Auricles, Part of which Tendon at the Egreſs of the *Aorta* in ſome Creatures, as in a Stag, becomes Bony; It's Shape is that of a Cone with it's Baſis upwards, and the Lower Part is called it's *Apex* or *Mucro*; It is Bigger in Men than in other Creatures, conſidering the Proportion of their Bodies, and Leſſer and more Denſe in Hot and Bold Men, than in the Cold and Cowardly; In Adult Perſons it is commonly Six Fingers Breadth Long, and Four Broad at the Baſis; Outwardly it is Covered with a proper Coat, which is Thin, but Strong and Denſe, and very hard to Separate from it, and is the ſame with the outer Coat of the Great Artery, as that, which Cloaths the Ventricles on the Inſide, is Continued unto and Common with that Thin Skin, that Covers the Inſide of the Arteries, like a *Cuticula*; and hence it is thought Probable by *Diemerbroeck*, that the Arteries borrow theſe Coats of the Heart, as the Nerves borrow their Two Tunicles from the *Pia* and *Dura Mater* of the Brain; Upon this Membrane, which Inveſts the Heart, there grows ſome hard Fat about the Baſis; It is not nouriſhed by the Blood or Chyle Received into it's Ventricles, but by the Veſſels of it's *Parenchyma*; It has Two Arteries, which Spring from the *Aorta* before it's Paſſage out of the *Pericardium*, and are called *Coronariæ*, becauſe they Encompaſs the Baſis of the Heart, like a Diadem, by fetching a Circuit on it's Surface, from whence they are branched ſeveral ways to the *Apex* of the Cone, where they Inoſculate; It has alſo as many Veins, which go by the ſame Name; and it's Nerves are Derived from the *Plexus Cardiacus* and *Par Vagum*; It is Diſtinguiſhed, in it's Parts, into it's Two *Auriculæ*, it's Two Ventricles, and it's *Septum*.

It's Auriculæ, *and their Syſtole and Diaſtole.*

THE *Auriculæ*, or Ears, are ſo called from ſome Similitude they have with thoſe of the Head, for they Riſe from a Long Baſis upon the Baſis of the Heart, and End in an Obtuſe Point, making an Obtuſe Triangle; They are Two Appendages of it, and are Seated over it's Ventricles, and are of the ſame Fabrick and Uſe, being both Muſcles, and made up of a like Order of Fibres, which are carry'd into oppoſite Tendons, whereof that at the Baſis of the Heart is Common to it, and theſe *Auriculæ*, and the other Runs along their upper Part; The Right is Larger and Softer, the Left is Leſs, but more Firm; Their Superficies is Smooth, when they are Filled, but Wrinkled, when Empty, and the Left more than the Right; When They are Cut open, there Appear in their Cavity many Fleſhy Columns Running from the Upper to the Lower Tendon, and betwixt Them there are pretty Deep Ditches, or Long Cavities, but Fewer in the Right, than in the Left; They are Dilated and Contracted, as the Heart is, but at Different Times; For the Syſtole of the Ventricles is at the ſame Time with the Diaſtole of the *Auriculæ*, and the Syſtole of the *Auriculæ* with the Diaſtole of the Ventricles; ſo that the *Auriculæ* Receive their Blood from the Veins, while the Ventricles Expell theirs into the Arteries, and when the Ventricles are Relaxed and Empty in their Diaſtole, the Auricles Force their Blood into Them by their Syſtole: They have Coronary Arteries and Veins, in like manner as the Heart, from the Former of which their Subſtance is nouriſh'd, and by the Latter the Superfluous Blood is carry'd Back to the Heart to be again Circulated thro' the Arteries; They ſerve to Receive the Venal Blood immediately out of the *Vena Cava* and *Pulmonaris*, and to Meaſure it into the Ventricles, into which, that they may Expell it with the Greater Force, Their Internal Fibres or Columns Ariſing from their Root, where they are Joined to the Baſis of the Heart, Reach directly outward towards the *Vena Cava* and *Pulmonaris*, and in the Syſtole of the *Auriculæ* Graſp the Blood Contained in their Cavity, like ſo many Fingers, and Squeeze it into the Ventricles, whilſt they are Relaxed in their Diaſtole.

It's Ventricles with their Conſtriction and Dilatation.

THE Ventricles Receive the Blood from their Auricles, and Expell it into the *Arteria Pulmonaris* and *Aorta*; The Right is the Wideſt, and almoſt Semicircular, but does not Reach down to the *Apex* or *Mucro* of the Heart, whereas the Left does, and is almoſt Round; Their Sides are Hollowed into Diverſe Interſtices or Furrows, and Interwoven with Carnous Fibres Reaching this Way and That; Which are more Numerous in Men's Hearts than in Thoſe of any other Animal, tho' ſuch as are Big, as Horſes, *&c.* have them Larger; Theſe Fibres or Fleſhy Columns ſerve to Streighten and Conſtringe the Ventricles, and the Furrows betwixt them help their Sides to Cloſe more exactly in their Syſtole; The Fibres are More and Stronger, and the Furrows Deeper in the Left Ventricle, than in the Right, and are alſo in the Side of the *Septum*, tho' that Side of it, which looks to the Right, is nearly Smooth; for there was occaſion for a Greater and Stronger Conſtriction in the Left, than in the Right, becauſe the Firſt Expells the Blood to the Extremeſt Parts of the Body by the *Aorta*, but the Laſt by the *Arteria Pulmonaris*, thro' the Lungs only.

It's Septum.

THE *Septum* divides the Ventricles from one another, and is a Carnous and Denſe Partition that ſtands like a Wall betwixt them; It is Hollow towards the Left Ventricle and has it's Fibres and Clefts, as was juſt now ſaid, but Convex and Smooth towards the Right; It has been a Conteſt with ſome, whether there is not a Paſſage thro' this *Septum* out of one Ventricle into the other, but none ſuch is found, nor is it likely there ſhould be any; becauſe, if there were, there would be no need of the *Foramen Ovale* and the *Canalis Arterioſus* in the *Fœtus*, by the Former of which the Blood paſſes out of the *Cava* into the *Vena Pulmonaris*, as it is Entering the Left Ventricle, and by the Latter out of the *Arteria Pulmonaris* into the *Aorta*.

It's Pericardium, *and the Blood and Water Contained in it.*

THE Heart is Incloſed by it's *Pericardium*, *Capſula*, or *Involucrum*, which is Membranous and of the ſame Figure; It Springs at the Baſis of it from the outer Common Coats of thoſe Veſſels, that Enter into the Heart, and which are borrowed from the *Pleura*; It's Outſide Adheres to the *Mediaſtinum* by many Fibres, and is Continued to it at the Baſis of the Heart, where the Veſſels Perforate it; It's Lower End is knit firmly to the Center or Nervous Part of the Diaphragm, which is ſaid by *Bartholin* to be Peculiar to Men, and that in all other Creatures it hangs Looſe; It has Nerves, Arteries, Veins, and Lympheducts, as other Parts, and any Tremors or Inordinate Vibrations are thought to Proceed from the Succuſſion of this Membrane, and to Differ from the Pulſation of the Heart; It contains in it a Serous Liquor, which in healthful Bodies is Reddiſh, like Water wherein Fleſh has been Waſhed, and is ſuppoſed to be Bred of Vapours Exhaleing from the Heart, which are Stopt and Condens'd by this Membrane, or elſe to Drop out of the Glands ſeated at the Baſis of the Heart, and what is Superfluous is Imagined to be carry'd off by it's Lymphaticks to the *Ductus Thoracicus*; This Liquor is not Naturally above Two Spoonfuls, tho' in Diſeaſed Perſons it ſometimes Increaſes to half a Pound, or a Pound; It ſerves for Moiſtening the Heart and making the Superficies Slippery, that it may Move the Better; Worms have been obſerved to Breed in the *Pericardium*, which Subjects the Perſons, who have them, to Palpitations of the Heart and Swoonings.

The Five Perforations of the Pericardium.

IT has Five Perforations: Firſt, One made by the Aſcending Trunk of the *Cava*; Second, Another by the Deſcending, both which Enter the Right Ventricle of the Heart; from whence there goes out the *Vena Arterioſa*, or *Arteria Pulmonaris*, into the Lungs, which makes a Third Perforation; A Fourth is made by the *Arteria Venoſa*, or *Vena Pulmonaris*, which Enters the Left Ventricle of the Heart; And a Fifth by the *Aorta* or Great Artery going out of the ſame.

The Aſcending Trunk of the Vena Cava, *which makes the Firſt Perforation.*

As to the Branches of the Deſcending *Cava*, they have been already Deſcribed, when we Treated of the Liver, and the Aſcending Trunk was Traced as far as the Midriff from the ſame Bowel, where we ſhall now take it up and purſue it; Upon the Paſſage thro' which it ſends forth into it's Subſtance the *Vena Phrenicæ*, which alſo Run thro' the *Mediaſtinum* and *Pericardium*, and are ſuppoſed by ſome to Abſorb the *Pus* Collected in the *Thorax*, from whence it is Circulated thro' the Heart, and at Length Diſcharged by Urine from the Emulgent Arteries.

The Foramen Ovale *and* Canalis Arterioſus.

FROM the Diaphragm the *Vena Cava* Aſcends Undivided to the Right Auricle of the Heart, but before it Enters it, having Pierced the *Pericardium*, it Emits the *Venæ Coronariæ* before-mentioned, which carry back the Superfluous Blood to the *Cava*; and where they open into it, there is a Valve fixed, which Permits the Blood to Return by them into the *Cava*, but Hinders any from Paſſing out of the *Cava* into Them; Before this Aſcending Trunk of the *Cava* opens into the Auricle, it is Joined by the other, which Deſcends from the *Claviculæ*, a certain Tubercle or Protuberance Intervening betwixt them upon their Junction, which Hinders the one from opening into the other in a Direct Line, and makes them go obliquely to the Left Hand, as they Enter the Auricle, otherwiſe the Deſcending Blood would have met the Aſcending to the Stoppage or Retardation of both; Immediately beyond this Protuberance out of the United Trunk, there goes a Paſſage called *Foramen Ovale* along the Baſis of the Heart to the *Vena Pulmonaris* in a *Fœtus*, juſt as it Enters into the Left Auricle, which Cloſes up and is Obliterated as ſoon as the *Fœtus* is Born; as alſo, from the *Arteria Pulmonaris* to the *Aorta* there is a Pipe called *Canalis Arterioſus*, which Conveys the Blood from the one to the other, and which upon the Birth Degenerates into a Ligament; Theſe Ducts are Formed, becauſe there is little or no Motion of the Lungs in the Womb, and no Paſſage of the Blood thro' them, Excepting what is Required for their Nutriment and Growth.

Concerning the United Trunk of the Cava *opening into the Right Ventricle of the Heart.*

THE United Trunk of the *Cava* opens by one Large Orifice into the Right Ventricle of the Heart, (but *Steno* affirms that it goes no farther than the Auricle,) into which is Poured all the Blood, that Returns in Circulation from all the Parts of the

Body, except the Lungs; At the Orifice of the *Cava* there Grows a Membranous Circle, which is Cleſt into Three Membranous Valves, looking Inwards and called *Tricuſpides*, which Permit the Blood to come in, but not to go out, and whoſe Action Dr. *Lower* thus Explains; Out of the Sides of the Right Ventricle there grow certain *Papillæ*, or Round and Long Caruncles or Fleſhy Columns, from whoſe Top Proceed ſome Tendinous Fibres, which are knit to theſe Membranous Valves, and Encompaſs the Orifice of the *Cava* ſo, that when the *Mucro* of the Heart is drawn up towards the Baſis in it's Syſtole, the Fibres, and conſequently, the Membranes or Valves are Slackened, and Hanging looſe are Driven upwards by the Blood that is Squeezed up in the Syſtole, by which means this Inlet is exactly Cloſed, ſo that no Blood can flow Back into the *Cava*, but is Expelled into the *Arteria Pulmonaris*, whoſe Orifice is now Open; On the Contrary, in the Diaſtole the *Mucro* Receding from the Baſis, the *Papillæ* and Fibres are Drawn down, and the Membranes and Valves with Them, by which the Orifice is Uncloſed, and a Paſſage Opened for more Blood to Flow in, the Former being Expelled by the Laſt Syſtole.

The Deſcending Trunk of the Cava *from the* Claviculæ, *which makes the Second Perforation.*

The Trunk of the *Cava*, which Deſcends from the *Claviculæ* has many Branches, which Empty themſelves into it, before it Diſcharges it ſelf into the Heart, which we ſhall only juſt Mention, Referring to Anatomiſts for a more Particular Deſcription of Them; As Firſt the *Azygos* or *Vena Sine Pari*, which Enters the *Cava* juſt before it's Tranſmiſſion thro' the *Pericardium*, and Receives into it the Inferior Intercoſtals from the Interſtices of the Eight Loweſt Ribs, on Each Side; from whence they Aſcend from the Eighth or Ninth *Vertebra* of the Breaſt to the Fourth or Fifth, and ſo up thro' the Right Side of the Cavity of the *Thorax*: The next are the Superior Intercoſtals, which are Derived from the Interſtices or Intervals of the Three or Four Uppermoſt Ribs, but ſometimes they Diſcharge themſelves into the *Azygos*, and then they are Wanting to the *Cava*; but it is obſervable, that where the *Azygos*, and the Superior Intercoſtals Enter the *Cava*, there are Valves placed, which Admit the Influx of Blood into it, and Prohibit the Reflux from it; After theſe, upwards, under the *Claviculæ*, the Subclavian Veins, one from the Right and the other from the Left, Empty themſelves into the *Cava*, where they Unite into one Deſcending Trunk, which Subclavian Veins, Continued out of the *Thorax*, are called the Axillar.

The Subclavian Receives ſeveral Branches Upwards and Downwards.

In it's Lower Side; First, The Mammary, which are Internal and External; The Former from the Ends of the Ribs, the Intercoſtal Spaces, and the Glands of the *Mammæ*; The Latter from the Navel and near the Epigaſtrick Veins, from whence they Aſcend to the ſaid Subclavian: But ſo Deſultory is the Courſe of the Veins, that ſometimes theſe Mammary Enter into the *Cava* and not into the Subclavian.

Second, The *Mediaſtina*, which is Derived from the *Mediaſtinum*, and ſometimes Diſcharges it ſelf into the *Cava*.

Third, The *Cervicalis* or *Vertebralis*, which is Derived from the *Vertebræ* of the Neck, and the Membranes, which Inveſt the Marrow contained in them.

Fourth, The *Muſcula Inferior*, which comes from the Lower Muſcles of the Neck and the Upper of the *Thorax*, and ſometimes Empties it ſelf into the Jugular Vein.

In it's Upper Side, First, The *Muſcula Superior* from the Upper Muſcles of the Neck.

Second, The External and Internal Jugulars, which have Valves to hinder the Return of the Blood out of the Subclavians; The External from the Membranes, which Cover the Brain, from the Fore-head, Temples, Head, Face, Chaps, and Neck. They Run juſt under the Skin, and are thoſe which are opened for Diſtempers of the Head, or a Quinzy, *&c.*

The Internal from the *Dura Mater*, and the Rough Artery or Wind-Pipe.

Into the Subclavian is alſo Inſerted, as before-mentioned, the *Ductus Thoracicus*, and the *Ramus Lymphaticus*, which brings the *Lympha* from the Arms, Neck, *&c.* but this ſometimes Enters the Jugular.

The Vena Arterioſa, *or* Arteria Pulmonaris, *which makes the Third Perforation.*

The *Vena Arterioſa*, or *Arteria Pulmonaris*, Obtains the Nature of an Artery, both in carrying Blood out of the Right Ventricle of the Heart to the Lungs, and in it's being Inveſted with a Double Coat, like other Arteries; At it's Riſe out of the Right

Ventricle, it's Orifice is Guarded with Three Membranous Valves, looking outwards, called the Semilunar, or Sigmoides, becauſe they Repreſent the Old Greek Sigma, or the Engliſh C; They are made, according to *Steno*, of the Tendons of the Fibres of the Heart, which go into the Subſtance of the Artery it ſelf; In the Syſtole they Open and Permit the Blood to Paſs out of the Ventricle into this Artery, but in the Diaſtole they Shut, ſo as none can Return; A little beyond theſe Valves, in a *Fœtus*, the *Canalis Arterioſus* Springs, which Runs croſs the Breaſt to the *Aorta*, and Conveys the Blood out of this Artery thither, without Paſſing thro' the Left Lobe of the Lungs, or thro' the Left Ventricle of the Heart, but, as was before ſaid, upon the Birth turns Ligamentous; After it's Paſſage out of the *Pericardium*, it Bends towards and Aſſociates it ſelf with the *Aſpera Arteria*, or Wind-pipe, and Attends it in all it's Ramifications thro' the Lungs; and where the Branches of the Wind-pipe End in the Little Cells or Bladders after Deſcribed, the Twigs of this Artery, being Interwoven with thoſe of the Vein, Embrace them like a Net, in order, as it is Imagin'd, that the Air may more Intimately mix with the Blood.

The Arteria Venoſa, *or* Vena Pulmonaris, *which makes the Fourth Perforation.*

THE *Arteria Venoſa*, or *Vena Pulmonaris*, Obtains on the other Hand the Nature of a Real Vein, in carrying Blood to the Heart, and in being Inveſted with a Single Coat only, as other Veins; It accompanies the Rough Artery, and the *Arteria Pulmonaris*, in all their Branchings in the Lungs, and conveys the Blood from the ſmall Twigs of the ſaid Pulmonary Artery by it's own Capillaries into Two Trunks, which afterwards Unite into one, which opens into the Left Ventricle of the Heart; At it's Orifice there are placed Two Membranous Valves, beſides which it has no other, called *Mitrales*, becauſe together they Reſemble a Biſhop's Mitre; They are of a ſtronger Contexture than the *Tricuſpides* in the Right Ventricle, and ſo are the Fibres, which Aſcend to them from the *Papillæ* or Fleſhy Columns, for the Reaſon above given; Theſe Valves ſhut in the Syſtole of the Heart, and the Orifice of the *Aorta* opens, by which means the Blood is Hindred from Returning into the Pulmonary Vein, and Directed to Proceed in the ſaid Great Artery; Juſt as the Pulmonary Vein Enters the Left Auricle, the *Foramen Ovale*, a Pipe or Canal, opens into it coming from the *Cava*, as was mentioned before, and at it's Orifice into this Vein there is a Valve placed, that hinders any Blood from Returning into the *Foramen*.

THERE is one Thing Remarkable in this Pulmonary Artery and Vein, That, whereas in all the other Arteries, the Blood is of a Bright Scarlet Colour and in the Veins of a Black Purple, on the Contrary, in the Pulmonary Artery it is of a Black Purple and in the Vein of a Bright Scarlet, which can be owing to nothing but to the Mixture of Air with it in the Lungs.

The Aorta, *or Great Artery, which makes the Fifth and Laſt Perforation.*

THE *Aorta*, or Great Artery, which is the Laſt Veſſel, that Perforates the *Pericardium*, is That, from which all the Arteries, Excepting the Pulmonary, are Derived; At it's Riſe from the Left Ventricle of the Heart, it hath Three Valves looking outwards, called *Semilunares*, being altogether like thoſe at the Orifice of the *Arteria Pulmonaris* in the Right Ventricle, and both They and the *Aorta*, according to *Steno*, are Conſtituted of the Tendons of the Fibres of the Heart; Theſe hinder the Blood from Returning out of the Great Artery into the Heart again; The Orifice of the *Aorta*, or the Tendon of the Heart, which is Continuous to it, in ſome Creatures, eſpecially in Stags, does often, as was ſaid before, and ſometimes in Men, become Bony; It Aſcends out of the Left Ventricle, and is immediately Turned into an Arch, and from thence Deſcends downwards, which is called the Deſcending Trunk, and that which is called the Aſcending, according to Dr. *Ruyſch*, is only Branches ſent upwards from the Bending Arch of the Main Trunk of the *Aorta*; Before it comes out of the *Pericardium* it conveys the Coronaries to the Heart, it's Auricles, and to it's own Coats; but when it has Pierced it, it is Divided into what is uſually Termed the Aſcending and Deſcending Trunk.

It's Aſcending Trunk, and it's Branches.

THE Aſcending Runs up under the *Vena Cava*, Lies upon the Wind-pipe, and preſently Sends forth Two Large Branches, the one to the Right, the other to the Left Arm, called the Subclavian, as Marching under the *Clavicula*, and after they are out of the Breaſt, the Axillar: They Send out ſeveral Branches, both from their Lower and Upper Side.

FROM the Lower, The Superior Intercoſtal to the Interſtices or Intervals of the Four Uppermoſt Ribs, to the Neighbouring Muſcles and Spinal Marrow; Theſe are ſometimes Propagated from the Cervical Arteries, coming out thro' the Holes of the *Vertebræ*.

FROM the Upper, FIRST, The Mammary to the Breaſts, and down the *Abdomen* to the Epigaſtrick Arteries Aſcending, with which they are ſuppoſed by ſome to Inoſculate, contrary to the Circulation of the Blood; ſince no Blood can Aſcend by the Mammary, nor Deſcend by the Aſcending Twigs of the Epigaſtrick.

SECOND, The Cervical or Vertebral to the *Vertebræ* and Muſcles of the Neck, the Spinal Marrow and it's Membrane, which Inveſts it, to the *Pia Mater*, on which a wonderful Net-like *Plexus* of them is Formed, to the Subſtance of the *Cerebellum*, and to the Carotid Arteries, with which uniteing, Part of the *Rete Mirabile* is made.

THIRD, The Muſcular to the Muſcles of the Neck and Arms.

AT the ſame Place or very Near, where the Aſcending Trunk ſends out the *Subclavian* Side-ways, The Remainder is Divided into Two, called *Carotides*, which Aſcend directly Upwards, tho' the Right ſometimes Ariſes from the Right *Subclavian*; They are ſuſtained at their Riſe by the *Thymus*, beſtow certain Twigs on the *Larynx*, Tongue, the Muſcles of the *Os Hyoïdes*, and the Neighbouring Glands, paſs up on each Side by the Wind-pipe to the Jaws, where they are each of Them Subdivided into the External and Internal Branches.

THE External and Smaller is Diſperſed into the Muſcles of the Cheeks, Fore-head, Temples, Lips, and all the outer Parts of the Head and Face, and into the Roots of the Teeth of the Lower Jaw.

THE Internal and Larger into the *Larynx*, Tongue, *&c.* the Glands behind the Ears, and the Spongy Parts of the Palate and Noſe, and the Roots of the Teeth of the Upper Jaw; The Remainder Climbs upon the Scull, and at it's Baſis is Divided into Two Branches.

THE Leſs and Hindermoſt is ſpent upon the Inner Muſcles of the Neck, the Membrane of the Spinal Marrow, and the *Dura Mater*, at whoſe *Sinus* it Ends.

THE Larger, likewiſe, is ſpent in ſeveral Twigs on the *Dura Mater*, and being Interwoven with many ſmall Slips of the Cervical Artery, Produces the *Rete Mirabile*, which is more Conſpicuous in Beaſts than Men; It afterwards Pierces thro' the *Dura Mater*, and Enters the *Pia*, Mixes with the Twigs of the Cervical Artery, with which it Accompanys the Spinal Marrow to the Loins; It ſends alſo one ſmall Branch with the Optick Nerve to the Eye, and ſupplying ſtill more Twigs to the Subſtance of the Brain and *Pia Mater*, which Unite with thoſe of the Cervical Artery, it makes the *Plexus Choroides*.

It's Deſcending Trunk and it's Branches.

THE Deſcending Trunk of the *Aorta* goes down by, and cleaves to, the Gullet, and is the Reaſon, why Perſons, when Hot, are ſo much Cooled by a Draught of Water; It's Branches are as follow,

FIRST, The Inferior Intercoſtals to the Interſtices of Eight or Nine of the Lower Ribs, the Marrow of the Back, the Muſcles of the *Vertebræ* and *Thorax*, and, according to *Ruyſch*, to the *Bronchia* of the Wind-pipe. When it comes to the Midriff,

SECOND, The Phrenical to the Diaphragm, *Mediaſtinum*, and *Pericardium*. When it comes down by the Spine to the Fifth *Vertebra* of the Loins,

THIRD, The Cœliacal, from the Fore-part of the Trunk, to the Stomach, the Hollow of the Liver, and the Trunk of the *Vena Portæ*; where it is Divided into Two Branches, the Right and Left.

THE Right, which is the Smaller, Aſcending from it's Upper Part, ſends out the *Gaſtrica Dextra* to the *Pylorus*, and the *Cyſticæ Gemellæ* to the Gall-Bladder.

FROM the Lower Side. 1. The *Epiplois Dextra* to the Hinder and Inner Leaf of the Caul, and to the *Colon* Annexed to it.

2. The *Inteſtinalis* to the *Duodenum*, and the Beginning of the *Jejunum*.

3. THE *Gaſtroëpiploïs Dextra* to the Bottom of the Stomach, and the Caul, which Adheres to it.

4. THE *Hepaticæ* to the Inveſting Membrane of the Liver, the *Capſula Communis*, the Gall-Bladder, and *Porus Bilarius*.

THE Remainder of this Right Branch Enters the Meſentery in ſeveral Twigs.

THE Left Branch of the *Cœliaca*, which is called the Splenick, and ſometimes Springs Immediately from the *Aorta*, is Larger than the Right, and ſends forth,

FROM it's Upper Side, The *Gaſtrica Major* to the Stomach, and then is Divided into the *Coronaria Stomachica*, which Encompaſſes the Upper Orifice of it like a Garland, and is Spread in Twigs upon it's Ventricle; and the *Gaſtrica Siniſtra*, which is Carry'd to the Upper Part of the Stomach and to the *Pylorus*.

FROM it's Lower Side, The *Epiplois Poſtica* to the Hinder Leaf of the *Omentum*, and the *Colon* Adjoining, and the *Epiplois Siniſtra* to the Lower and Left Side of the *Omentum*.

JUST as this Splenick Branch Enters the Spleen, there Ariſes out of it's Upper Part *Vas Breve Arterioſum*, which goes ſtrait to the Left Part of the Bottom of the Stomach, and the *Gaſtroëpiploïs Siniſtra*, which, being ſuſtained by the Upper or Fore Leaf of the *Omentum*, ſends ſome Twigs to the Stomach, and to the ſaid *Omentum*; After which the Splenick Branch Enters into the Spleen.

FOURTH, The Superior Meſenterick from the Fore-part of the Trunk to all the Upper Part of the Meſentery, where it is Accompanied by the Meſaraick Vein of the *Porta*, to the *Jejunum*, *Ileum*, and Part of the *Colon*.

FIFTH, About the Second *Vertebra* of the Loins from each Side of the Trunk an Emulgent to the Kidneys, where it is Separated into a Thouſand Twigs, which are Inveſted, with the Veins, in one Common *Capſula* Borrowed from the *Pelvis*, and End with their Capillaries in the Glands; where the *Serum* is Secreted, and carry'd from them by the Urinary *Siphons* into the *Pelvis*, and from thence thro' the *Ureters* into the *Veſica*, in order to be Expelled the Animal Syſtem.

SIXTH, The Spermatick, or *Arteriæ Præparantes*, from the Fore-part of the Trunk, ſeldom from the Emulgents, to the *Epididymides* and *Teſtes*, and in Women, to the *Ovaria*, and Bottom of the Womb.

SEVENTH, The Inferior Meſenterick, a little before the *Aorta* is Divided into the *Rami Iliaci*, to the Lower Region of the Meſentery, to the *Colon*, *Rectum*, and *Anus*, where it makes the Internal Hæmorrhoidal Artery.

EIGHTH, The *Lumbares*, out of the Back-ſide of the *Aorta*, to the Neighbouring Muſcles of the Loins, the *Peritonæum*, and, thro' the Holes of the *Vertebræ*, to the Membrane of the Spinal Marrow, and to the Marrow it ſelf.

WHEN the *Aorta* is Deſcended to the Fifth or Laſt *Vertebra* of the Loins, and to the Top of the *Os Sacrum*, it begins to Climb upon the *Vena Cava*, under or behind which it Paſſed thus far, and is from thence Divided into the *Rami Iliaci*, and immediately upon the Diviſion there Springs out the *Arteria Sacra*, whoſe Twigs Penetrate into the Marrow of the *Os Sacrum*.

THE *Rami Iliaci* are Subdivided into the Interior, and Exterior Branches.

FROM the Interior Proceed. 1. The Inferior Muſcular to the *Glutæi*, or Muſcles of the Buttocks, to the Iliack Muſcle, and the *Pſoas*.

2. THE Hypogaſtrick, to the Bladder, *&c.* and in Women to the Bottom of the Womb and it's Neck, from whence Iſſue the *Menſes*, in their Monthly Purgation, and to the *Anus*, where it makes the External Hæmorrhoidal Artery.

3. THE Umbilical, by the Sides of the Bladder, betwixt the Membranes of the *Peritonæum*, to the Navel, and Paſſes, in a *Fœtus*, into the *Placenta Uterina*, but after the Birth, Turns to a Ligament.

FROM the Exterior. 1. The Epigaſtrick, betwixt the *Peritonæum* and *Muſculi Recti* of the *Abdomen*, to the Mammary Artery, at the Navel; tho' it does not Inoſculate with it, as is ſuppoſed.

2. THE *Pudenda*, to the Secret Parts.

THE *Rami Iliaci* after This go out of the *Abdomen* into the Thighs, where they are called *Crurales*.

The Chief Controverſies of Anatomiſts Relateing to the Heart, and it's Veſſels.

UPON the Heart and the Veſſels, which Appertain to it, There are Three Grand Controverſies, or Queſtions.

FIRST, What is the Cauſe of the Heart's Motion?

SECOND, How the Pulſation of the Heart, and Circulation of the Blood is Performed?

THIRD, How Blood is made of Chyle, from whence it's Heat and it's Colour, and whether the Body is Nouriſhed by it, and in what Manner?

§. 2.

§. 2. We ſhall now, as uſual, Inquire what Solution our Doctrine of Expanſive and Contractive Forces can give of theſe Phænomenons.

It is Agreed on all Hands, that a Red-Beating Speck Appears in the *Embryo* before the Heart is Formed, and that this Ariſes upon the Impregnation of the *Ovum*; That the *Ovum* has Originally an Expanſive Force belonging to it, is manifeſt in Fowls, both from it's Yellow Colour, which is ſome Indication of it, as it Approaches to that of the Sun and of Fire, the Great Sources in Nature of the Expanſive, and from it's Strength, as an Aliment, which chiefly conſiſts in that Force, as we have before ſhewn; On the other Hand, the *Semen*, which Impregnates it, has a Contractive Force, and accordingly was never deemed fit for Nouriſhment, and it's Colour is near to a White, as Froſt, and Snow, and Salt, the Greateſt Inſtances we know of the Contractive, are; ſo that the One may be Eſteemed the Animal Fire or Warmth, and the Other the Animal Froſt or Cold, or Salt, of the Growing Syſtem: Whilſt therefore the *Ovum* Continues Unimpregnated, the Expanſive Force of it Remains Undiſturbed and Quieſcent in it ſelf; but as ſoon as the Contractive Force, which is Oppoſite to it, Supervenes, a Motion and Ferment is Cauſed, and the Expanſive of the *Ovum* is Excited, and the Red-Beating Speck is Produced, which by it's Pulſe declares it's Force to be, what we have Mentioned; And now the Animal Flame begins, which Burns to the laſt Period of our Lives.

How the Heart or Red Beating Speck is Produced in an Embryo, *and by what Forces the Impregnation of the* Ovum *is Perform'd, and the Animal Syſtem begins to Riſe.*

§. 3. Thus in Mechanical Forces, where a Contractive and Expanſive Act oppoſite to each other, a Motion is continued ſo long, as thoſe Forces ſubſiſt; Thus it is in the Revolutions of the Heavenly Bodies; and Thus in the Mixture of Chymical Liquors of a Contractive and Expanſive Nature, all which we have already Explained: Life alſo has been Compared, and not Unjuſtly, to a Lamp and a Taper, as it depends upon the like Forces; For here there is the Expanſive of Fire or Flame, to which the Oily or Expanſive Subſtance continually Runs and Aſſimilates it ſelf, and the Contractive of Air, and if either of Theſe are not Regularly ſupplied, it is Extinguiſhed and Dies: Laſtly, that this Animal Flame Commences in the Red-Beating Speck, and from the Forces alledged, is Proved even in our own Syſtem, from the Common Inflammations and Redneſſes Produced in it, which are always in a Wound by the Expanſive Force of the Blood, and the Contractive of Air or Cold Mixing with it; For if the Air is kept off, the Expanſive of the Blood Preſerves it's own Craſis and Temper; And Salts, which are of a Contractive Nature, applied to a Freſh and Large Wound cauſe it to Redden and Feſter, but Balſams and Salves, which by their Inflammableneſs are of a Gentle Expanſive, Cheriſh and Aſſimilate with the Blood, and gradually Cloſe and Heal it; Colds likewiſe produce Fevers, and a Contractive Force, Mingling with the Expanſive of the Blood, Exalts it into the Greateſt Heat and Ferment; And the Venal Blood, which is of a Deep Purple, by it's Paſſage thro' the Lungs and Pulmonary Artery, that is, by Meeting with the Contractive of the Air there, is Raiſed into a Bright Scarlet, which is the Colour of the Arterial Blood, or which is the ſame, into an Higher Fever or Flame, or into a more Elevated Degree of the Expanſive, and which is immediately Perceived by the Pulſation, which Enſues, and the Vivid Colour it puts on, which are both Irrefragable Arguments of ſuch a Force and the Increaſe of it. And the ſame Blood Expoſed to the open Air in Venæſection Changes into a like Scarlet, as is known to every Obſerver. Hence alſo it is, that *de Graef* in the Diſſection of Rabbits, half an Hour, Six, Twenty Four, Twenty Seven, and Forty Eight Hours, after the *Coitus* or Injection of the *Semen*, or Contractive Force, found the *Cornua* of the *Uterus* to Redden, and the Limpid Liquor of the *Ovum* gradually to change into that Colour.

The foregoing Account Confirmed from the Mechanical Forces, from the Revolutions of the Heavenly Bodies, from the Mixture of Chymical Liquors, from a Lamp or a Taper, and from the Common Inflammations Produced in our own Syſtems, from the Arterial Blood, and de Graef's *Experiments in Diſſection.*

§. 4. The Animal Flame being Kindled in the Manner Deſcribed, that is, the Red-Beating Speck being Produced as above, it Scatters, like Fire, and Diſperſes it's Influence, and Converts what is Alimentary to it, that is, the Lower Degree of the Expanſive in the *Ovum*, into it's own Force, from whence Streaks of Blood are preſently after Obſervable in it, the Contractive Force, like the Air, ſtill Fanning and Exciteing the Vital Flame; And as the Aliment of the *Embryo* or *Fœtus* is of an Expanſive Nature, as what we afterwards Receive in for our Nouriſhment is, it becomes the *Pabulum* or Fuel of the Blood or Animal Fire, by which there is a Continual Increaſe of it; And the Contractive Force is on the other Hand ſupplied by the

How the Animal Flame is Preſerved and Continued by a New ſupply of the Expanſive and Contractive Forces. And what are the Rudiments of the Heart and Brain.

the *Albugineous* Liquor ſurrounding the *Ovum*, and by the Nerves of the Womb, and of the *Plexus Meſenterii Maximus*, which Run into the *Ovarium*, by the Aſſiſtance of Which, the Seminal Principle Subdues other Forces to the Contractive, as the Sanguineous does to the Expanſive, from which Conjunction of the Contractive Forces are Derived the Rudiments of the Brain, which at Firſt is little more than a Watry and Thin Fluid.

The Reaſon of the Streams of Blood before the Heart is Produced, and of the Diſtance of the Heart from the Brain.

The Red-Beating Speck, which is afterwards the Heart, therefore being the Seat and Center of the Expanſive, and the Brain that of the Contractive, and being Forces oppoſite to each other, as the Red-Beating Speck ſends out Rays and little Streams of Blood towards the Latter, ſo the Latter emits Nerves and Saline or Contractive Juices towards the Former, in order to Preſerve the *Æquilibrium* betwixt Them: And the Diſtance betwixt the Heart and the Brain is Determined, when that *Æquilibrium* is Fixt and Aſcertained in the *Fœtus*, and is ſtill in Proportion Enlarged in Men, as the Expanſive and Contractive Forces Increaſe by new and continual Additions of Nouriſhment to both, till the Animal Syſtem is Arrived to it's utmoſt Maturity.

How therefore the Blood is Formed before the Veſſels, which contain it, which is Acknowledged by Dr. Harvey, *and is a Matter of Aſtoniſhment to him; and the Right Ventricle of the Heart is made.*

§. 5. From this Account it is manifeſt, that the Blood is Formed before the Veſſels, which contain it, according to what is Acknowledged and Wondered at by the Eminent Dr. *Harvey* and the Anatomiſts, who have Followed him; But the Red-Beating Speck being, as was ſaid, the Center and Seat of the Expanſive, Freſh Blood is continually Amaſs'd to it, by it's Power of Converting Alimentary and Expanſive Juices into it's own Nature, as Fire does the Fuel, which is Miniſtred to it, and by the Law of Nature, which Aſſembles Forces of the like Kind together.

On the Contrary, the Nerves from the Brain Endeavour to ſurround it with their Contractive Force to Balance the Expanſive, from whence the Right Ventricle of the Heart is Formed; for in a *Fœtus*, as there is no uſe of the Left, by Reaſon of the *Canalis Arterioſus* Conveying the Blood from the *Arteria Pulmonaris* immediately to the *Aorta*, ſo we have no occaſion at Preſent to conſider it, but to ſuppoſe the Heart to Conſiſt only of One.

How the Heart is the Source of Vital Heat, why the Wounds in it are Mortal, and why it hangs looſe in it's Capſula.

§. 6. We ſhall now therefore from this Doctrine go Regularly on, and Aſſign a Reaſon for all the Phænomenons of the Heart and it's Veſſels in Order, as they are before Recounted from Anatomiſts.

It is the Source of Vital Heat, that is, the Blood, which is Contained in it, the Heart it ſelf being nothing more than a Thick Muſcular Coat, which Inveſts it; The Heat of the Blood Ariſes from the Expanſive Force Acting in Oppoſition to the Contractive, as has been ſhewn before in the Red-Beating Speck, and is the Caſe of an Efferveſcence Produced in Chymical Liquors of Contrary Forces; And the Blood in the Heart is the Source of this Vital Heat, becauſe the Blood here is Originally made from the ſaid Red-Beating Speck, and afterwards Converts other Alimentary Juices into the ſame Subſtance, till Growing into a Maſs, it is ſurrounded by the Contractive with Muſcular Coats, and Included in the Ventricle; The Wounds in it are Mortal, for the ſame Reaſon, as the Cutting of any conſiderable Artery is ſo, the Blood being thereby Let out into the Body, the Circulation Diverted, and the whole Animal *Æquilibrium* entirely Deſtroyed; It hangs looſe in it's *Capſula*, and is only ſuſpended in the Breaſt by it's Veſſels; For the Red-Beating Speck was ſolitary and alone, and by Degrees Collected a Maſs of Blood or the Expanſive Force to it, which afterwards was Cloathed with the Fibres of the Contractive.

Why the Figure of it is Conical, and why the Mucro *Inclines to the Left.*

§. 7. It's Figure is Conical with the Baſis upward; becauſe the Principal Conteſt betwixt the Expanſive and Contractive Forces is on that Surface, which lies Intermediate to Them, that is, to the Heart and Brain, and therefore the Expanſive will there make the Greateſt Reſiſtance to the Contractive and will Diſplay it ſelf the Moſt, after which the Expanſive will be Continually and Gradually Diminiſh'd, and the Contractive cloſe in upon it accordingly, from whence it will Surround it in ſtill Leſſer Circles, till it Ends in the *Mucro* and *Apex* of a Cone; Which *Mucro* or Tip Inclines a little to the Left Side, becauſe the Chief Weight of the Action betwixt the Expanſive and Contractive Forces lies on the Right, that is, the Right Ventricle is Loaded with Blood and Preſſed by the Contractive, whereas the Left, if Formed, is as yet Empty, which therefore muſt Elevate the *Mucro* to the Left, and ſink the Loaded Ventricle to the Right.

Why it is ſituate Nearer to the Brain in Men than in Brutes, Why it Adheres to the Pericardium *at the Baſis, and why it's Subſtance Differs in Thickneſs on the Right Side, the Left, and at the* Apex *or Tip.*

§. 8. It is ſituate Nearer to the Brain in Men than in Brutes; becauſe the Contractive Force is Greater, as we have before Evinced, in the one than the other, by which the Heart is drawn Nearer to it in the Firſt, than in the Laſt Caſe.

It Adheres to the *Pericardium* at the Baſis, but not at the Tip; becauſe the Contractive uſes all it's Efforts there, where there is the Greateſt Expanſive Exerted againſt it, and therefore Unites the *Pericardium* to the Muſcular Fibres of the Heart; On the Contrary, where the Expanſive Force is Weak, and the Contractive ſufficiently Prevalent, as at the *Mucro*, the *Pericardium* do's not Preſs to it's Aſſiſtance.

It has a Firm, Thick, and Denſe Subſtance; becauſe the Expanſive Force of the Blood Amaſſed together being Great Required a ſtrong Contractive to Balance and Encloſe it; and therefore the Arteries, which contain a Leſſer Expanſive Force of the Blood, have Thinner Coats, and the Veins, whoſe Expanſive Force of Blood is ſtill more Diminiſhed, Thinneſt of all: For the ſame Reaſon, the Subſtance of the Heart is Thinner and Softer on the Right Side, thro' which the Venal Blood Flows, which has a Leſs Expanſive, and Thicker and more Denſe on the Left, thro' which the Arterial is carry'd, and which has a Greater Expanſive; but the Tip is the moſt Hard and Compact, from the Expanſive, which is here ſubdued, giving little Diſturbance to the Contractive, and from the Contractive Forces Uniteing more firmly together after their Conteſt with, and Superiority over, the Expanſive by the Law of Nature, by which Similar Forces Aſſemble and Cement together, and are Excited, if not Vanquiſhed, by a Contrary Action.

The Reaſon of the Courſe of the Fibres of the Heart, and why the Fibres of the Left Ventricle are Stronger than thoſe of the Right.

§. 9. Farther, in Reſpect of the Fibres, which Compoſe theſe Coats, the Innermoſt Run Spiral-Wiſe from the Baſis to the Tip, Deſcending from the Left to the Right; becauſe the Expanſive Force of the Blood lying in the Right Ventricle, the Contractive Force is carry'd in it's Action againſt it from the Left to the Right; the Contractive alſo Deſcends, as it is Derived from the Brain, and Spirally, becauſe the Expanſive Force Exerting it ſelf in Oppoſition to it, it cannot Deſcend in a Strait Line from Left to Right, and therefore muſt do it in a Curve; That is, every Step, which the Contractive takes, is ſomething Elevated by the Expanſive above a Rectilinear Deſcent, and conſequently is made to Wind about the Heart in a Spiral: The Second Courſe of Fibres Deſcend from the Right to the Left, For the Contractive Meeting with an Oppoſition from the Expanſive in it's Former Courſe, the ſame Contractive, Deſcending ſtill from the Brain, Attempts a Contrary, which by the Expanſive is notwithſtanding again Diverted into a Spiral, which Forms the Middle Coat: Laſtly, the Contractive Force from the Brain ſending out Freſh ſupplies againſt the Expanſive of the Blood, it at Length proceeds in ſtrait Lines from the Baſis to the Tip, or in Lines Parallel to Them; becauſe the Balance is now Compleated betwixt the Two Forces, and the Contractive Left to go in it's own Direction, and ſo the Heart with it's outmoſt Coat is Finiſhed: The Fibres of the Left Ventricle are ſtronger than thoſe of the Right; becauſe the Expanſive Force of the Arterial Blood is Greater than that of the Venal, and therefore the Contractive Force in the one Caſe muſt be Superior to that in the other, to make an *Æquilibrium* of the Expanſive with the Contractive.

Why a Tendon is ſpread over the Baſis of the Heart, and why the Heart is Bigger in Men than other Creatures, and yet leſs in Bold Men, than in the Cowardly.

§. 10. There is a Tendon ſpread over the Baſis of the Heart; becauſe the Expanſive Force there Exerts it's whole Effort againſt the Contractive, and conſequently the Contractive from the Brain will be the moſt Conſtipated and Confirmed at that Surface in Oppoſition to it: For which Reaſon alſo at the Egreſs of the *Aorta*, where the Expanſive of the Blood is ſtill Increaſt, that Part of the Tendon in ſome Creatures becomes Bony, that is, is Guarded with a Greater Contractive.

Hence the Heart is Bigger in Men than in other Creatures, becauſe the Brain is ſo, being as Big again as an Oxe's, for to Preſerve an *Æquilibrium* betwixt the Two Forces, if the Source of the one is Enlarged, that of the other muſt be in Proportion; but it is Leſſer and more Denſe in Bold and Couragious Men than in the Cowardly, becauſe the Spirituous, Nervous, or Contractive Force is Greater in the Firſt, and the Expanſive and Sanguineous in the Laſt; which is Certain in Experience, as the Meagre and the Enthuſiaſtick are more Nervous and Bold than the Fat and the Sanguinary.

How the Fat about it's Baſis is Produced, and the Coronariæ *Formed, and*

§. 11. The Fat about it's Baſis is Produced from a Mixture of the Blood, and Nervous Juice, as other Fat; and it is not nouriſh'd from the Blood Contained in it, but by the Veſſels Diſperſed in it's *Parenchyma*: For as ſoon as the Blood is Pulſed

out

it's Fleſh and Subſtance Concreted and Made.

out of the Left Ventricle of the Heart thro' the *Aorta*, Part of it Runs immediately to the Heart by the Appetite of Nature, which carries it towards a Similar Force, the Expanſive within the Heart, from whence it was Expelled by the Contractive, and forms the Innumerable Branches of the *Coronariæ* upon the Baſis of it, where the Expanſive is the moſt Senſible and Strong; from thence it Deſcends to the Tip, and Penetrates into and Diffuſes it ſelf in Various Rivulets and Meanders thro' the whole Subſtance; On the other Hand, the Contractive Force in like Manner, and by a like Appetite of Nature Aſſembles to the Contractive of the Heart, and Attends this Expanſive from the *Plexus Cardiacus* and *Par Vagum* of the Nerves, and Congeals and Hardens it into Fibres and Fleſh, by which means the *Æquilibrium* is ſtill Preſerved betwixt the Two Forces, and the Parts Equally Nouriſhed.

The Cauſe of the Syſtole and Diaſtole of the Heart.

§. 12. The Right Ventricle of the Heart being made, as above, with it's Fibres and Coats, an eaſy Account is given of the Reaſon of it's Motion and the Pulſation of it; For the Blood by it's Expanſive Force Swells and Dilates it, both that within it's Cavity, and that which is Spread and Scattered in it's Subſtance, that is, the Fleſhy Part of it, which is the Cauſe of it's Diaſtole; and the Nervous Fibres and Coats by their Contractive Force Streighten and Compreſs it, from whence it's Syſtole Ariſes; And theſe Forces being in an Equal Balance, or nearly ſo, mutually ſucceed each other by Turns, neither being able to Overcome, Surmount, or Deſtroy and Annul the other; Like the Weight of a Clock and it's Pendulum, in which the Former is the Contractive and the Latter the Expanſive derived from the Expanſive of the Hand, which puts it into Motion; and which therefore Conſiſts of Two Oppoſite Forces Balanceing each other, from whence it's Motion Commences, and which, if either of them is Stopt or Hindered from it's Exertion, Ceaſes.

How the Beginning of the Arteria Pulmonaris, *the* Canalis Arterioſus, *and the* Aorta *with it's Branches, are Formed.*

§. 13. The Blood, being by the Syſtole or Conſtriction of the Heart Driven out of it in a *Fœtus*, by it's Appetite to the Expanſive hovers upon the Baſis, whither the Contractive Force Purſues and Surrounds it, and as the Blood is ſtill Pulſed forwards and Expands it ſelf, and the Nervous or Brainy Subſtance by it's Contractive Incloſes and Inveſts it, The Beginning of the *Arteria Pulmonaris* and the *Canalis Arterioſus* is Formed, and after that, the *Aorta* with it's ſeveral Aſcending and Deſcending Branches; For a Progreſſive Expanſive Incloſed by a Progreſſive Contractive muſt of Neceſſity produce hollow Tubes and Canals, ſuch as the Arteries are.

And from hence it is, that the Inner and Outer Coats of the Arteries are the ſame with thoſe of the Heart, being Conſtituted in the ſame Manner: And as to the Aſcending and Deſcending Branches of the *Aorta*, why the Blood ſhould Deſcend is not hard to Conceive, ſince it is Endued with it's own Proper Gravity, but why it ſhould Aſcend, or Receive a Lateral Direction, is ſomething Difficult to Explain, unleſs upon this Doctrine of the Expanſive and Contractive Forces.

How the Branches of the Aorta *Aſcend upwards, and in General, How the Blood Veſſels and Nerves are capable of Receiving all Manner of Directions.*

§. 14. The Reaſon of which therefore is, becauſe, as the Contractive Force of the Nervous Subſtance is carry'd from the Brain towards the Heart, ſo the Expanſive of the Sanguineous is Reciprocally carry'd from the Heart towards the Brain to Preſerve the *Æquilibrium* of the Animal Syſtem, by their Forces Acting in Oppoſition and in Counterpoiſe to each other; And this is ſo True, that the Carotid and Cervical Arteries, thro' which the Blood Aſcends to the Brain, are ſo Large and Numerous, that a Third Part at leaſt of the whole Maſs is Conveyed thither by Them, which, Paſſing thro' the Capillary Arteries in ſmall Quantities, is Congealed and Transformed into the Contractive Force of the Brain, in order to ſupply the *Medulla Oblongata*, which is the Trunk of the Nerves, with new Matter for their Conſumption upon the ſeveral Parts, to which they are Branched and Propagated; And this made *Malpighius* think it Probable, that the Coagulative, or Concreſcible, *Serum* was Filtred in the *Cortex* or Glandulous Part of the Brain from the Arterial Blood, and from thence Transferred by the Fibres of the *Corpus Calloſum* to the ſaid *Medullæ*; Upon the ſame Account, the Expanſive Force of the Blood is carry'd in a Lateral Direction by it's Acting Contrary and in Oppoſition to the Contractive from the *Vertebræ* of the *Thorax*, Back and Loins, and the ſeveral Nerves and Fibres ſent from thence; and which will alſo ſolve all other the Innumerable Variety of Directions, Upwards, Downwards, and Tranſverſe, or Oblique, in which the Sanguineous and Nervous Matter is Diſperſed thro' the whole Body.

Why the Proceſſes of the Heart and

§. 15. We are likewiſe hereby Informed, why the Proceſſes of the Heart and Brain open towards each other, whereas the Parts, which are Averſe, are Incloſed; For the

Blood and the Brain Exerting their Actions continually againſt each other, that is, their Expanſive and Contractive Forces, there muſt of Courſe be a continual Outlet to them that way, but the Expanſive in the Heart being Leſs at the Tip, as was before Explained, the Contractive Prevails and Inveſts it; On the Contrary, if the Brain is not Sollicited by any Action from the Expanſive, it Cloſes and Contracts of it ſelf, and therefore, under the *Os Frontis*, the *Synciput*, and *Occiput*, is Continuous without any ſuch Proceſſes.

Brain open towards each other.

§. 16. Thus far we have gone, ſuppoſing the *Fœtus* to be ſtill in the Womb, whilſt the Lungs are of no Uſe, and the *Canalis Arterioſus* and *Foramen Ovale* obtain their Proper Offices: But after the Birth, Things are otherwiſe, for then the Air Ruſhing into the Lungs, gives a new Turn to the Circulation of the Blood, and it now Paſſes no Longer thro' the *Canalis Arterioſus* from the Pulmonary Artery into the *Aorta*, nor from the *Vena Cava* into the Pulmonary Vein thro' the *Foramen Ovale*; which not being kept open by the Expanſive Force of the Blood Acting againſt their Sides, their Contractive Force Prevails, by which they Cloſe, and the Canals are thereby Converted into Ligaments; On the other Hand, the Blood from the Right Ventricle of the Heart Expands it ſelf againſt the Incurring Force of the Contractive of the Air, in order to Oppoſe and Balance it, from whence it is Diſperſed into the Innumerable Branches of the Pulmonary Artery, whoſe Coats are ſupplied to it by the Method above Deſcribed; But being able to Expand it ſelf no farther by the Oppoſition, which is made to it from the Contractive Force of the Air, it Returns in Streams towards the Heart the Fountain of the Expanſive, from whence the Branches of the Pulmonary Veins are Formed; and the Right Ventricle being already Poſſeſſed, it Forces it ſelf into the Left Side, and Makes or Compleats the Left Ventricle; and being Excited and Exaſperated into an Higher Degree of the Expanſive by the Oppoſition it has met with, it Penetrates to the very Tip, and Dilates it ſelf ſo, that the Cavity of the Left Ventricle becomes Prominent into the Right, and the *Septum* is Concave to the Former, and Convex to the Latter; but here being Reſiſted by the Coats of the Heart, and Propelled by their Contraction, it is Driven into the *Aorta*, which is already made to Receive it.

How after the Birth, the Canalis Arterioſus *and* Foramen Ovale *are Changed into Ligaments, and the Branches of the Pulmonary Artery and Vein are Formed, as alſo how the Left Ventricle of the Heart is made.*

§. 17. From hence it is Plain, that if there was any Communication betwixt one Ventricle and another by a *Foramen* thro' the *Septum*, this whole Contrivance of Nature would be Deſtroyed; And Either, when the Blood in the Right Ventricle was Expanded into the Lungs, the Blood in the Left would Follow thro' ſuch *Foramen* and not Paſs into the *Aorta*, from whence the *Aorta*, and all the Arteries Derived from it, would Change into Ligaments, and the Body Wither into a Skeleton; Or Elſe it would Paſs into the *Aorta* and not into the *Foramen*, in which Caſe the *Foramen* would Change into a Ligament, and then it would have been in Vain for Nature to have made it, that is, only to ſtop it up again; Or laſtly, the Blood would Flow out of the Right Ventricle into the Left, without Paſſing thro' the Lungs, from whence it would want it's Accenſion, from the Contractive Force of the Air, into Arterial Blood, which is ſo neceſſary to it's Pulſation and the Circulation of it, and the Pulmonary Artery and Vein would be Contracted into Ligaments: From all which it is Evident, that as no *Foramen* was ever obſerved in the *Septum*, ſo that there Really is none; Namely, both from the Diſtinct Formation of the Ventricles, and from the neceſſary Conſequences, which would Enſue in the Human Syſtem, which are not Experienced in it.

That there is no Communication betwixt the Left Ventricle and the Right by a Foramen *thro' the* Septum, *and the Reaſon of it.*

§. 18. This Account alſo Furniſhes us with a Reaſon, why all the Blood Flows to the Right Ventricle, and is Diſcharged and Diſperſed from the Left; The Firſt, becauſe, before the Left Ventricle was Formed, or Compleated, the Blood Aſſembled to the Heart by that Law of Nature, which makes Similar Forces to Cement and Unite together; The Laſt, becauſe, as the Influx of the Blood continually Increaſes it's Quantity, there muſt be ſome way for it's Diſtribution and Efflux, which therefore is by the Pulmonary Artery and Vein into the Left Ventricle, from whence by the Contractive Force of it's Coats it is Expelled into the *Aorta*, as already Deſcribed.

Why all the Blood Flows to the Right Ventricle, and is Diſcharged and Diſperſed from the Left.

§. 19. The Auricles are of the ſame Nature with the Ventricles, and ſerve for the ſame Uſe, and are only the Firſt Efforts of the Contractive Force to Encloſe the Expanſive of the Blood, which is Finiſhed and Effected in the Ventricles; and therefore the Fibres in the Auricles, as before in the Ventricles, are Stronger in the

What the Deſign of the Auricles is, and how the Pulſation of them is Accounted for.

Left

as well as that of the Ventricles, and the **Aorta.**

Left than in the Right, that is, the Contractive Force is ſo, of which they Conſiſt; becauſe the Expanſive of the Arterial Blood is Greater and Stronger than the Venal, to Balance which a ſtronger Contractive is Required.

The Pulſation of the Auricles Proceeds likewiſe from the ſame Cauſe with that of the Ventricles, Namely, from the Expanſive Force of the Blood, and chiefly from it's Accenſion in the Lungs by the Contractive Force of the Air, and from the Contractive Force of their Coats; So that it is very Probable, that the Principal Pulſation Ariſes from the Left Auricles and Ventricles of the Heart, when the Blood has been Inflamed, and the Expanſive Force of it Excited in the Lungs; However it is Plain, that the Syſtole of the Ventricles muſt be at the ſame Time with the Diaſtole of the Auricles, and the Syſtole of the Auricles with the Diaſtole of the Ventricles; And the ſame Law ſeems to be Obſerved thro' the whole Arteries, that the Syſtole of the Superior Parts ſhould be at the ſame Time with the Diaſtole of the Inferior, and the Syſtole of the Inferior, with the Diaſtole of the Superior, or *Vice Verſâ*; Since This Appears to be Requiſite in a Courſe of the Expanſive, as of the Blood, and of the Contractive, as of the Coats, which Inveſt it; For ſuppoſing the Blood to be Entering the Auricle, by it's Expanſive Force concurring with the Sanguineous Fibres, It immediately Dilates and Diſtends it, till the Contractive Force of the Nervous Fibres and Coats being Excited, It Repreſſes on the Blood and Fleſhy Fibres, and Conſtringes the Auricle, by which the Blood is Driven into the Ventricle, which is Dilated and Diſtended by it, whilſt the Auricle ſubſides and is Contracted; On the other Hand, the Contractive Force of the Ventricle is now Exerted, and whilſt the Blood is Expelled from it by it's Conſtriction, New Blood Flows into the Auricle, which again by it's Expanſive Force Dilates and Diſtends it.

In like Manner, in any Two Contiguous Parts of the *Aorta*, or it's Branches, in the Deſcending Trunk, when the Blood Enters the Superior Part, a Dilatation is Cauſed by it's Expanſive Force, and that of the Sanguineous or Fleſhy Fibres, which is ſucceeded by a Conſtriction from the Contractive of the Coats and the Nervous, and which Propells the Blood to the Inferior Part, which now Swells and is Dilated, whilſt the Superior Sinks and is Contracted, and whilſt the Inferior is Contracted after it's Dilatation, the Superior is Dilated by a Freſh Influx of Blood, and a Renewal of the Expanſive; And what is ſaid here of a Superior and Inferior Part of the Deſcending Trunk of the *Aorta*, obtains of an Inferior and Superior in the Aſcending: And by theſe Methods a Progreſſive Pulſation appears to be Propagated thro' the whole Sanguineous Syſtem, not much Unlike to, or Differing from, the Vermicular or Periſtaltick Motion of the Inteſtines; So that Nature in the Animal Frame, as well as in the Mundane, Acts Agreeably and Conſiſtently with it ſelf, ſince it's Motions are Uniform, and are Derived from the ſame Principles; and which is a Forcible, if not an Invincible, Argument for the Truth of Thoſe, which we have Alledged.

That the Pulſe of the Arteries in the ſeveral Parts of them is Diſtinct and Independent of the other Parts, and of the Heart, and the Reaſon.

§. 20. From hence it is Manifeſt, that the Pulſe of the Arteries does not Depend upon, nor is Communicated to Them from the Pulſation of the Heart, but that every Pulſe is Diſtinct and Independent, and Ariſes from the Influx of Blood into the ſeveral Parts, and the Reciprocal Contraction and Dilatation of thoſe Parts from the Expanſive of the Blood and of the Sanguineous or Fleſhy Fibres, and the Contractive of the Nervous; And therefore it is, that in Experience we find the Pulſe of the Wriſt keeps no Time with that of the Temples, or of the Upper Part of the Noſe, nor Theſe with the Grand Pulſe of the Heart, which is Eaſy for any one himſelf to Obſerve, and is an Indication of Their being Separate and Independent Motions, and ſuch, as are Agreeable to the Account, we have given of Them.

How the Heart comes to Beat after it's Separation from the Animal Syſtem.

§. 21. This likewiſe Informs us, how the Heart comes to Beat, and to Retain a Pulſation even after it's Separation from the other Parts of the Body; becauſe, tho' the Blood no longer Flows into it, yet the Fleſhy or Sanguineous Fibres Preſerving their Expanſive Force, ſo long as the Heart continues Warm, Act againſt the Contractive of the Nervous; From whence there will be a Reciprocation of Motion, till the Expanſive is quite ſubdued, and the Heart becomes Cold and Contractive: And this is farther Confirmed from the Pulſe being Revived, after the Heart has Ceaſed Beating, by an Affuſion of Warm Blood, or even Warm Water upon it; For thereby the Expanſive of the Sanguineous, or Fleſhy, Fibres is again Excited, and Enabled to Prolong it's Conteſt with the Contractive, till it again Languiſhes and Expires, and the Contractive finally Triumphs and Prevails.

How the Circulation of the Blood is Performed.

§. 22. So that from this Doctrine the Circulation of the Blood, it's Colour and Nutrition, and the Motion of the Heart, are Neceſſary, tho' they are Difficulties, which have hitherto Confounded and Puzzled the Greateſt and moſt Celebrated Anatomiſts; For the Blood Aſſembles to the Heart by that Law of Nature, by which Similar Forces are Collected to each other, and it is Expelled from thence by the Contractive Force of it's Coats and Nervous Fibres, which cannot fail of Produceing the Circulation Mentioned; More particularly, according to the foregoing Account, the Heart being Formed, the Blood is Pulſed out of the Right Ventricle into the Left, and ſo into the *Aorta*, for it is Impoſſible for it to Proceed thro' the *Mucro* or Tip; The Cauſes, Springs, and Directions of which Motions have been already Explained; From the *Aorta* it is carry'd thro' the Branches of it to all Sides, by the Contractive Force of the Coats and Nervous Fibres, which Protrude and Propell it from the Heart towards the Extreme Parts, where it is Made or Congealed into Fleſh by the Contractive Force of the ſaid Nervous Fibres, and becomes the Nouriſhment of the Carnous Syſtem; But, the Blood ſtill Flowing into thoſe Parts, by it's Expanſive Force being now Superior to the Contractive, it Aſcends, and Tends towards the Heart by the afore-mentioned Law, from whence it was Driven, but, being ſtill Followed and Balanced by the Contractive, it is Inveſted with Nervous Coats, from whence the Veins are Formed, and the Circulation Perfected.

How the Parts of the Body are Continually Renewed.

§. 23. ALSO, we may from hence give an Account, how the Parts of the Body are continually Renewed; for the Blood being Condenſed into Fleſh by the Contractive Force of the Nervous Fibres, as it Rots and Putrifies it Grows Expanſive, and is therefore carry'd off by the Expanſive Force of the Superfluous Blood in the ſeveral Parts, and is ſupplied by the Condenſation of New Blood into Fleſh, from whence Ariſes the Perpetual Renovation of Them; But when the Expanſive Force of the Blood grows ſo Weak and Languid, that it cannot Elevate and Raiſe the Corrupted Parts, an Univerſal *Tabes* Enſues, and a Diſſolution of the whole Animal Oeconomy.

The Colour of the Blood, and the Motion of the Heart Explained.

§. 24. As to the Colour of the Blood we have ſhewn, that it Ariſes from an Increaſe of the Expanſive in the *Ovum* by the Oppoſition of the Contractive of the Seminal Principle, and that the Chyle is Raiſed into that Colour by Mixing with the Blood, as Fuel is Converted into Fire; And as to the Motion of the Heart, we have Explained it from the Expanſive of the Blood, and the Carnous Fibres on the one Hand, and the Contractive of the Animal or Brainy Subſtance, and the Nervous Fibres on the other, Acting againſt each other, ſo as neither of the Forces can Prevail, from whence Proceeds a Reciprocation of Them.

The Opinions of the Anatomiſts Vulgarly Received, concerning the Heart and the Blood, Confuted from what foregoes.

§. 25. THERE ſeems nothing therefore Remaining in Relation to the Heart, Excepting to Examine the Famous *Alphonſus Borellus*'s Opinions Concerning it, ſince what we have ſaid will ſufficiently Confute the Fancies of Anatomiſts, which have been vulgarly Received about it; As, That it's Motion Proceeds from an Influx of Animal Spirits conveyed by the Nerves, altho' the Heart Moves in the *Embryo*, before either Brain or Nerves are Formed, and in Living *Fœtus*'s when cut out from the Body and Entirely Separated from all the Parts of it; Or elſe from the Rarefaction and Accenſion of the Blood, tho', according to Dr. *Lower*'s Experiment and his Friend's, the Heart continues it's Pulſation, when no Blood Flows into it, and only Beer and Wine, or Broth, are Derived into it's Ventricles;

THAT Chyle is Changed into Blood by the Vital Spirit, and Active Principle of the Latter Looſening, by Fermentation, the Salt, Sulphur, and Spirit of the Former, and Aſſimilateing and Aſſociateing Parts to it, which are of a like and ſuitable Nature;

THAT Blood becomes Hot by a Vital Flame, which is Lodged in the Heart, and which Heats the Blood, as it Paſſes thro' it, tho' it is Clear, the Heart is nothing but a mere Muſcle; or by a Saline Subſtance Mixing with a Sulphureous, or an Acid with an *Alkali*, tho' no ſuch Subſtances are Obſerved in the Blood; or by an Accenſion of it, which is Unexplained;

And laſtly, That the Colour of the Blood is owing to the Heart, or to the Mixture of Salt and Subacid Juices with Sulphureous, as in the Diſtillation of Sal Nitre, or in Pouring Oil of Vitriol on Conſerve of Roſes, by which a Pale Red is Changed into a Deep one: Theſe we ſhall omit particularly to Conſider, becauſe they are Refuted by what foregoes, or, ſo far as they ſtand Good, are Explicable by the Precedeing Doctrine; The Vital Spirit and Sulphur, being Different Expreſſions of our Expanſive Force, and the Acid and Saline Subſtances, of the Contractive.

Borellus*'s Account of the Heart and it's Action.*
De Motu Animalium, Cap. 5. Par. 2. Prop. 37.

§. 26. As to *Borellus* in order to Explain the Mechanical Motion of the Heart, he Firſt gives the Structure of it from *Malpighius*, *Lower*, and *Bellinus*, and makes it not to be a *Parenchyma*, but a Muſcle, conſiſting of ſtrong Carnous Fibres, of the ſame Priſmatick Figure, of the ſame Colour, Conſiſtence, and Tenacity, with the Fibres of other Muſcles, which cannot be Drawn out into a Greater Length, as they are Renitent to a Diſtraction, but are Contracted of their own Accord, have a Tenſion, are Inflated, and acquire an Hardneſs, when they Act in the Heart's Pulſation, and in Boiling become Groſs and Turgid, and are eaſily Torn in Pieces and Broken; But this Fibrous Conſtitution of the Heart Differs from that of other Muſcles, it's Fleſh being Firm, Hard, Uniform, and Dyed with a Red Colour, not Lax and Soft, nor are it's Priſmatick and Carnous Columns Separated from it's Membranes, and it's Innumerable Tendinous Fibres, as the Carnous Fibres of the other Muſcles are; Thus alſo it's Carnous Fibres are not in Strait and Parallel Lines, but Spiral, and Variouſly, and with a wonderful Artifice, Interwoven with each other, ſomething Agreeable to what has been before Deſcribed.

Besides which, there are Ten Millions of Millions of the Ramifications of Nerves, Derived from the *Par Vagum*, Scattered and Diſperſed thro' the Carnous Fibres of the whole Heart; After which he Proceeds to Inform us of the Two Coronary Arteries from *Bartholin*, and of the Auricles, and the Trunk of the *Vena Cava*, all which were before Mentioned.

De Motu Animalium, Cap. 5. Par. 2. Prop. 38.

In a following Propoſition he farther ſhews the Action of the Heart, as before he had given the Structure of it; That in Pulſation, it's whole Carnous Subſtance, as is Evident from Senſe, is, like that of other Muſcles, Inflated upon the Tenſion, and Hardened with the utmoſt Violence, but that the Swelling of the Fibres is not Deſigned by Nature, as in other Muſcles, to ſhorten the Diſtance betwixt the Extremities, and by that means to Draw them together, and the Joints, in which they are Inſerted; On the Contrary, in the Heart the Fibres are Shortened, that they may be Inflated and Swell, and thereby Straiten and Contract the Concave Surface of it, in order to Preſs out and Expell the Blood, which it Contains; which is Apparent from hence; That in every Pulſation or Tenſion of the Heart, the Contents of it are in Fact Driven into the Arteries, as by a Syringe, and if we Thruſt a Finger thro' a Wound made into a Live Heart, which *Bellinus* and *Lower* Obſerved, it will, at every Pulſation or Tenſion of it, be Caught and Encloſed as in a *Forceps*, and the Fleſh, upon it's Inflation and Hardening, Surrounds and Embraces it with Force, and Buries it in it's Subſtance, whilſt the External Surface of the Heart is not Increaſed or Altered by ſuch a Turgeſcence or Inflation.

De Motu Animalium, Cap. 5. Par. 2. Prop. 43, 44, 45, 46, 47, & 48.

What is afterwards Alledged to ſolve this Repletion of the Cavity of the Heart, from an Hollow *Glomus*, Compoſed of Threads Equally Thick, and of a like Conſiſtence, Wound Spirally Round a Bladder, blown up to Form an Intermediate Cavity, that if the Cavity of the *Glomus* is filled up by a Moiſtening of the Threads, the Internal Spires of the *Glomus* muſt be Wrinkled and Pleated, whilſt the External Remain in their full Tenſion, from whence the Mechanical Operation, by which the Cavity of the Moiſtened *Glomus* is filled up, is Explained, is ſo Abſurd and Ridiculous an Account of the Repletion of the Cavity of the Heart in it's Pulſation or Tenſion, that, however Mathematical it may Appear by the Figures it makes uſe of, it ſcarcely Merits an Anſwer.

The Repletion of the Cavity of the Heart not ſolved by the Madefaction of the Glomus.

§. 27. For, tho' it is certain, that if the Cavity of the *Glomus* is filled up by a Moiſtening of the Threads, thoſe Threads, be they Circular or Spiral, muſt be bent Inwards in *Plicæ* or Wrinkles in order to Penetrate into and Poſſeſs ſuch Cavity, yet it is not Evident, that the Cavity of the *Glomus* will be filled up by Moiſtening the Threads, or that they will Deſcend into ſuch Cavity by their Madefaction; On the

Contrary, Threads, which are Lax and Flaccid, by Moiſture become more Stretched and Shorter, whereas this Doctrine ſuppoſes, that Threads, which are Stretch'd, by Moiſture are Rendered more Lax, Flaccid, and Longer.

BESIDES, This Doctrine Informs us, that the Cruſt of the *Glomus* and the External Threads, of which it is Compoſed, do not Change their Figure by Madefaction, and there is no Reaſon Aſſigned, why the next Interior Coat of Threads ſhould do it; 'tis True, we are Told, that there is an Inflation of the Internal Threads, which Augments their Superficies, and ſince the External Coat is Immoveable, ſuch Augmentation of the Superficies muſt be ſpent Inwards towards the Center of the *Glomus*, by which it will become Wrinkled; but an Inflation of the outward Coat is likewiſe Acknowledged, and yet no Augmentation of the Superficies Owned; If therefore the Superficies of the outward Coat is not Augmented by Madefaction, why ſhould the Inner? If it is, why ſhould the Inner Tend in Wrinkles to the Center of the *Glomus?* Moreover, This is contrary to the Experiment in the Heart, in which the outward Surface is not Augmented, to Explain which the *Glomus* is Introduced.

FARTHER, Suppoſing the Madefaction of the Threads of the Interior Coats was capable of Protruding them in Wrinkles towards the Center or Cavity of the *Glomus*; Here would be a Languid Motion of the Internal Parts of the *Glomus* towards it's Cavity or Center, but how will this ſolve that Force and Vehemence, with which the Heart Acts in Pulſation? Here would be a Soft, Looſe, and Pulpy, Subſtance from the Relaxation of theſe Spirals into the Cavity of the *Glomus*, but where ſhall we find from thence the Hardneſs and Induration Acquired upon the Muſcular Tenſion? On the Contrary, the Principles, we have Advanced of the Expanſive and Contractive Forces, furniſh us with a Complete Solution of the Phænomenons Propoſed.

Borellus*'s Phænomena of the Heart ſolved by the Doctrine of the Expanſive and Contractive Forces.*

§. 28. THE Carnous Fibres cannot be drawn out into a Greater Length, but are Renitent to a Diſtraction, whilſt they are Contracted of their own Accord; Becauſe they conſiſt of the Expanſive Force of the Blood ſubdued by the Contractive Force of the Nervous Fluid, by which they are Rendered Tenacious and Solid, the Contractive Force therefore Prevailing, the Fibres are Diſtracted Hardly, but Contracted Eaſily: They are of a Priſmatick Figure; Becauſe the Expanſive Force, Exerting it ſelf in their Formation, and being Oppoſed by the Contractive, Shoots into Angles, as is done in all other Chryſtallizations, and the Number of the Angles are Different, according to the Different Proportion of Force betwixt the Expanſive and Contractive, as we have before Explained: They become Turgid in Boiling, and are eaſily Torn in Pieces and Broken; Becauſe, by the Application of the Expanſive Force of Heat and Fire, the Contractive is Diminiſhed, by which their Parts in a Turgeſcence are Separated farther from each other, and in Tearing and Breaking of them are entirely Diſunited: They have a Tenſion, are Inflated, and Acquire an Hardneſs, in the Pulſation of the Heart; Becauſe, when the Blood Flows into the Ventricles of it, the Expanſive Force is exceedingly Increaſed, and Raiſes and Excites the Remaining Expanſive in the Fibres, which therefore Swell and are Dilated; This likewiſe cauſes the Contractive Force to Exert it ſelf with Greater Vigour in the Fibres, in Oppoſition to the Expanſive, to which the Nerves from the *Par Vagum* Joining their Contractive, an Hardneſs is Produced: And from this vaſt Contention of Forces the Cavities of the Heart are Filled, and, the Contractive Prevailing, the Expanſive Force of the Blood is Expelled into the Arteries, and the Heart is Cloſed, till it is again opened by a new Influx of the Expanſive Force of Blood, which is in like Manner Driven out, as before.

See Chap. 3. §. 4. of this Book.

THE outward Surface of the Heart in the mean Time is little or nothing concerned in this Action; Becauſe, as we have already ſhewn, the Contractive Force is there ſo fully Eſtabliſhed, that it is not Affected with the Expanſive of the Influent Blood.

See §. 9. of this Chapter.

THE Fleſh and Carnous Fibres of the Heart are Firmer and Stronger than thoſe of other Muſcles; Becauſe the Conteſt of the Two Forces is here Greater, and the Contractive Prevailing muſt be likewiſe here the Greateſt in Reſpect of any other Carnous Fibres.

AND for the ſame Reaſon, the Carnous Fibres in the Heart are more ſtrictly Joined and Cemented with it's Membranes and Tendinous Fibres, which are of a Nervous and Contractive Nature, than in other Muſcles; Becauſe the Expanſive Force of the Blood being Greater, the Contractive Forces are more united together in order to Oppoſe and Balance it.

FROM whence Appears alſo the Neceſſity of ſuch an Infinite Number of Ramifications of Nerves from the *Par Vagum*, which have a Contractive Force, to ſupport the *Æquilibrium* againſt the Expanſive of the Incurring Blood.

See §. 9. of this Chapter.

AND why theſe Fibres of the Heart are Spiral, we have before Explained, which will give a Solution, why thoſe of other Muſcles are Direct and Parallel.

THIS Doctrine therefore Declares to us plainly, how the Cavities of the Heart are filled by a Tenſion and Inflation of the Fibres of it, how they become Hard, Conſtipated and Cloſe, and how this Action is Performed with the utmoſt Vehemence and Energy, which is not done by the *Rugæ* or *Plicæ* of the Threads of the *Glomus*, and the Madefaction of Them.

De Motu Animalium, Cap. 5. Par. 2. Prop. 53. 54.

FROM hence alſo an eaſy Account may be given, why the *Mucro* of the Heart in it's Syſtole ſtrikes againſt the Left Part of the Breaſt; Becauſe after the Blood has Paſſed thro' the *Vena Pulmonaris*, it becomes more Accended, and by Conſequence more Expanſive, the Contractive Force will therefore be Greater on that Side, and the Conteſt betwixt both the Forces Irritated and Increas'd; from whence, as we have ſhewn, the Pulſation, Tenſion, or Erection, of the Heart Ariſes, and therefore the Action of the Heart will Preponderate to the Left; And as to it's Auricles, we have already Conſidered, and Given an Explanation of, the Syſtole and Diaſtole of Them.

Borellus's *Explanation of the Force and Power of the Motive Faculty of the Heart, and of the Efficient Cauſes of it's Motion.* De Motu Animalium, Cap. 5. Par. 2. Prop. 56. to 76. & Cap. 6. to Cap. 7.

§. 29. WHAT Remains of *Borellus* upon the Heart is to Inquire into the Force and Power of it's Motive Faculty, and into the Immediate Efficient Cauſes of it's Motion.

As to the Firſt, he tells us after a Series of many Mathematical Propoſitions. *1ſt.* That the Motive Force of the Fibres of the Heart, conſidered by it ſelf, is able to ſuſtain a Greater Weight than of 3000 Pounds. *2d.* That all the Arteries of an Animal, after Pulſation, could not Subſiſt, if they were wholly Exhauſted of their Blood, and therefore always Retain ſome in Them after ſuch Pulſation. *3d.* That the Motion of the Blood in the Arteries has Thrice the Velocity of that, with which the Heart is Moved and Impells the ſame Blood. *4th.* That the Power of the Heart, which Conſtringes it, is Leſs than the Reſiſtence, which the Blood Contained in it's Ventricles Exerts, in a Subſeſquialterate Proportion. *5th.* That the Force, which the Blood Contained in the Ventricles ſuffers from the Compreſſion of the Heart, is Equal to the Force, with which the ſame Blood, like the *Embolus* of a Syringe, Impells the Blood into the Arteries, to whoſe Reſiſtence it has the ſame Proportion, as 1 to 40 nearly. *6th.* That the Abſolute Motive Force, by which the Heart is Conſtringed, is to the whole Force, with which the Blood in the Arteries is Reluctant to it's Expulſion, as 1 to 60. *7th.* That the Motive Force of the Heart Exceeds in it's Moment the Reſiſtence of the whole Blood of the Arteries, and the *Faſciæ*, which Hinder their Dilatation, which Reſiſtence is Greater than the Force, which Reſults from a Weight of 180000 Pounds. *8th.* That in every Pulſation of the Heart, either a whole Maſs of 3 Ounces of Blood, or ſome Portion of it, is Expelled from the Heart, not into, but on the Outſide of, the Arteries by a Motive Force Diſtinct and Different from the *Embolus* of the Heart, Conſidered as a Syringe. *9th.* That the Cauſe, which Expells the Blood on the Outſide of the Arteries thro' the Orifices of them, is the Compreſſion and Reſtriction of the Arteries by the Mechanical Force of the Human Syſtem, by which the Fibres of the Veſſels and Bowels are Contracted. *10th.* That the Power of the Heart in one Pulſation only ſurmounts a Reſiſtence, which is Greater than a Weight of 135000 Pounds, and ſince there are at Leaſt 1000 Pulſes in an Hour, it will in that Time have ſurmounted a Reſiſtence, which is Greater than a Weight of 135000000 Pounds, and in a Day, a Reſiſtence Greater than a Weight of 3140000000 Pounds, an Amazeing and Incredible Force, if it were not ſo, that the Force of Percuſſion in it's own Nature is ſo Vaſt, that it is Able to Surmount any Finite Reſiſtence.

As to the Second, or the Efficient Cauſes of the Heart's Motion, he Aſſerts contrary to the Ancients. 1*ſt*. That the Immediate Cauſe of the Motion of the Heart, which is a Muſcle, does not Differ from that which makes the Muſcles of the Joints to Move. 2*d*. That the Firſt and Mediate Cauſe of the Motion of the Heart does Differ from that, which Actuates the other Muſcles. 3*d*. That the Motion of the Heart is Performed by certain Stated and Neceſſary Laws of Mechaniſm, as well as that of other Automatons. 4*th*. That it is Poſſible, the Motion of the Heart may be Effected by the ſame Animal and Cognoſcitive Faculty, by which that of the Muſcles of the Joints is Produced, tho' we do not Obſerve it, by Reaſon of it's being ſo Habitual to us.

THESE are the Chief Propoſitions of *Borellus* in Relation to the Heart, beſides thoſe, which we have already Conſidered, and which we ſhall now Examine.

Borellus's *Proof of the Motive Force of the Fibres of the Heart Inſufficient and Weak upon ſeveral Accounts.*

§. 30. AND FIRST, as to the Motive Force of the Fibres of the Heart being able to ſuſtain a Greater Weight than of 3000 Pounds, it is Proved upon a Suppoſition, that all the leaſt Fibres of Different Muſcles in the ſame Animal are Equally Strong, and Exert an Equal Motive Force in the ſame Time; and that therefore, ſince the Carnous Fibres of the Heart are nearly Equal in Bulk to one of the Temporal Muſcles, and one of the Maſſeters, and their Motive Force is known, that of the Heart may be likewiſe Determined: But it is a large Conceſſion to allow, that the leaſt Fibres of Different Muſcles in the ſame Animal have an Equal Force; and we might as well Preſume, that the Blood obtains as Great an Expanſive Force, and the Nervous Fluid a Contractive in the Extreme Parts, as in the Heart and the Brain, as that the Fibres, which are Compounded and Formed of thoſe Forces, are every where the ſame; The Contrary rather ſeems to be Evident, that the Fibres Vary and Differ in their Forces, according to the ſeveral Degrees of the Expanſive Force of the Blood, and of the Contractive of the Nervous Fluid, of which they are Conſtituted and Made.

IN order likewiſe to Prove this Motive Force of the Fibres of the Heart, the Cortex of it is Imagined to Repreſent a Gun, it's Internal Fibres, upon their Turgeſcence and Inflation, ſerve for the Powder upon it's being Fired, and the Blood, Expelled from it, is the Bullet Diſcharged; From whence it is Reaſoned, that as every Grain of Powder in it's Exploſion Impells a Correſpondent Particle of the Bullet, and all the Grains together Impell ſo many Particles of the Bullet, as there are Grains, ſo in like Manner each of the leaſt Fibres of the Heart Acting together Impell Equal Particles of the Sanguineous Bullet; and it's whole Reſiſtence is Compounded of ſo many Particles, every one of which is Equal to the Power of one of the leaſt Fibres, as there are leaſt Fibres in the whole Heart: But is it not ſomething Extraordinary, that here the Heart is made to Reſemble a Gun, and it's Fibres the Exploſion of Gun-Powder, when before it was a *Glomus*, and it's Fibres Expreſſed by the Madefaction of Threads, And after a Syringe, and it's Fibres the *Embolus?* Is not this to Reconcile Fire and Water? And to Play the *Proteus* inſtead of the Philoſopher? Beſides, the Exploſion of Gun-Powder, which is ſo neceſſary to this Doctrine, is not Truly and Juſtly Explained, whilſt the Particles of it, and the Number of them, are only Conſidered, as if all Matter were Similar, and not their Real Force, which, in Diſſimilar, may be much Greater in a Particle of One Kind, than a Bare and Common Impulſe in a Thouſand of Another.

What the Truth is in Reſpect of the Motive Force of the Heart.

§. 31. WHAT therefore we ſhall Conclude with upon this Propoſition is only, that tho' we may give an Account of the Motion, or Motive Force, of the Heart, yet it is not likely, that we can Aſcertain the preciſe Degree of it's Force, excepting in General, that it is much Leſs than what is here Aſſigned, and that it is Little more than what Exceeds an *Æquilibrium* of Two oppoſite Forces; That the Heart does not Surmount the whole Maſs of Blood by it's Pulſations and Ejecting it out of it's Cavities, but that in Reſpect of it ſelf the Blood is in an Equal Balance of it's Parts nearly, it's Expanſive Force being throughout the Human Compages not Extremely Different, and the Exceſs of the Contractive Force above it in the Nervous Syſtem ſeems to be the Cauſe of it's Expulſion from the Heart, it's Promotion thro' the Arteries and Veins, and conſequently of it's Circulation, as we have before Evinced.

Second, That therefore the Arteries are never Empty, but always Retain ſome Blood, and are even Generally almoſt Full, is Aſſented to and Granted; For otherwiſe, neither the *Æquilibrium* of the Expanſive in the Blood could be Maintained, nor the Exceſs of the Contractive in the Nerves Exerted, nor conſequently the Pulſation of the Heart and Arteries Continued, which Ariſes from the Conteſt of thoſe Two Forces; This therefore we readily Admit, and it is farther juſtified by Fact and Experience.

Third, That the Motion of the Blood in the Arteries has thrice the Velocity of That, with which the Heart is Moved and Impells the ſame Blood, is Proved upon this Suppoſition; That the Inflation of the Heart, the Reſtriction of it's Cavities, the Expulſion of the Blood from the Ventricles, the Motion of it within the Arteries, and the Protruſion of the *Cruor*, or of the Blood which was Pre-exiſtent in Them, are all Performed in the ſame Time; Whereas there muſt be an Inflation of the Heart before the Cavities are Filled, and the Cavities muſt be filled before the Blood is Expelled; and the Motion of the Blood within the Arteries is as much owing to the peculiar Contractive Force of Them, as to the Expulſion from the Heart; and the Promotion of the *Cruor* belongs alſo to the ſame Cauſe, according to what has been before Explained.

Fourth, That the Power of the Heart, which Conſtringes it, ſhould be Leſs than the Reſiſtence, which the Blood, Contained in it's Ventricles, Exerts, in a Subſeſquialterate, *viz.* as 2 to 3, or any other Submultiple Proportion, is Inconceivable; Since, if the Reſiſtence of the Blood within the Heart was Greater than the Compreſſive or Contractive Force of it, which way would it be Poſſible for the Blood to be Expelled out of it? On the Contrary, we ſuppoſe the Expanſive Force of the Blood to be Inferior to the Contractive of the Muſcular Fibres; Beſides, the Preſent Propoſition Proceeds upon a Reaſoning, which Preſumes, that the External Fibres Act as a Cord Revolved Round a Globe or a Cylinder, and that therefore the Power, which Contracts the External Fibres of the Heart, is to the Reſiſtence of the Blood Compreſſed, as the Semidiameter of a Circle to it's Circumference, or Leſs than as 1 to 6, and that the Internal Fibres Act as a *Cuneus*, or an *Embolus*, of a Syringe, and Impell the Blood from the Periphery of the Heart to it's Center: To which there needs be no other Anſwer given, than that this Philoſophy, if it Pleaſed, might make the Heart a Milſtone, which was able to Grind all our Aliment into Blood, and there would be an End of the Matter; for how will a Cord and a Cylinder, or an *Embolus* or a Wedge, give us any Account of the Erection and Inflation of the Heart, and of it's Exceeding Life and Energy? which are not to be Repreſented by ſuch Dead and Unactive Powers, and can be only ſolved by the Expanſive and Contractive Forces we Defend.

Fifth, And for the ſame Reaſon we have no occaſion to Examine into the Fifth, Sixth, Seventh, Eighth, Ninth, and Tenth Propoſitions before Mentioned, which all Depend upon the like Precarious Fancies.

What are the Efficient Cauſes of the Heart's Motion.

§. 32. As to the Second Series of Propoſitions concerning the Efficient Cauſes of the Heart's Motion, there is no neceſſity of Inquiring into them particularly, we ſhall only ſay, that we have already Explained what they are; and perhaps there will be found to be no Great Diſagreement in this Celebrated Author from what we have Aſſerted, Excepting that, as he in General Affirms in *Prop. 3d*, That the Motion of the Heart is Performed by certain Stated and Neceſſary Laws of Mechaniſm, as well as That of other Automatons, and *Prop. 4th.* That the Motion of the Heart may be Effected by the ſame Animal and Cognoſcitive Faculty, by which that of the Muſcles of the Joints is Produced, without giving any Account how this may be done, ſo we have on the Contrary ſhewn the Way and Manner of it from the Laws of the Expanſive and Contractive Forces, tho' ſuch a Mechaniſm is Impoſſible to be ſolved by the Common Laws of the *Cuneus* or *Embolus*, or a Cord Revolved about a Globe or a Cylinder, which this Philoſophy Eſpouſes.

Nor can we allow what Dr. *Drake* Propoſes for a Solution of the Diaſtole of the Heart, which he Confeſſes is Unexplained by Dr. *Lower*, *Borellus*, and the beſt and moſt Accurate Anatomiſts, Namely, that it is owing to the Air Incumbent upon the Lungs, and which Acts as an Antagoniſt Muſcle to the Heart; ſince the Pulſe of the Heart does not keep Time with the Action of the Lungs, For we can Breath Faſter or Slower, whilſt the Pulſe Continues Uniform; nor can it be owing to the Moment and Pondus of the Influent Blood, ſince Fluids, which Paſs in a continued Canal, as the Blood in the Heart and Arteries, are in an *Æquilibrium*, and have not any peculiar Weight or Preponderancy at all; And as to the Syſtole, which he thinks ſufficiently Explained by thoſe Learned Men, we muſt Alledge, that however they may Agree in making Contraction the Proper and Natural State of the Heart, or any other Muſcle, they have not ſhewn, how it comes to be ſo, which we have before Accounted for from the Contractive Force of the Nervous Syſtem.

My Intention to have Proceeded to Inquire particularly into the Lungs, Brain, Eyes, Muſcles, Bones, and Marrow.

§. 33. I Intended from hence to Proceed to the Lungs, to the Brain, the Eyes, the Muſcles, Bones, and Marrow, and to Inquire into Them in the ſame particular Method, which I have hitherto Preſcribed to my Self, and into all the Remaining Phænomenons of the Animal Syſtem.

How the Lungs and Noſtrils in General are Formed, and why the Latter are betwixt the Fore-head and Mouth, and the Former Terminate in the Thorax.

In Reſpect of the Lungs, I would have ſhewn from the ſame Doctrine of the Expanſive and Contractive Forces; That the *Bronchia* of them and their Veſicles or Bladders are Formed from the Contractive of the Nervous Syſtem, and the Expanſive of the Air; That the Expanſive of the Air obtains a Middle Proportion betwixt the Contractive of the Brain, and the Expanſive of the Blood and the Aliment; That therefore it's Entrance into the Animal Frame, in the *Fœtus*, is betwixt the Fore-head, where the Contractive of the Brain Prevails, and the Mouth, which is made by the Expanſive of the ſaid Aliment; That the Noſtrils are Flatter at Firſt, and afterwards more Prominent by the above-mentioned Expanſive of the Air; and That the Air, which is of a Middle Force betwixt the Contractive of the Brain, and the Expanſive of the Blood and Aliment, Terminates it's Progreſs in the Lungs by the Superiority of thoſe Forces, which have their Canals and their Conveyances in Pipes and Tubes Diſperſed thro' the whole Syſtem.

What in General the Brain is, and it's Frame and Conſtitution.

In Reſpect of the Brain, I would have likewiſe Evinced; That it Conſiſted of a Cold and Contractive Force; That the Blood-Veſſels in it, which are of an Expanſive, are Small and Few upon the Account of the Prevalence of the Contractive; That yet the Degrees of the Contractive are Different in it, the one Part being more Conſtipated and Denſe, and the other more Watry and Fluid, or Expanſive; That from the Different Natures of theſe Forces, we are to Judge of the Conſtitution of the Brain, and it's Influences and Effects upon the Mind, or the Contrary, and not from the Texture of it's Parts, or the Diſtinctions made of Them, by the Nomenclators in Anatomy.

How the Eyes are Formed, what their Nature, and whence their Senſations are the moſt Delicate.

In Reſpect of the Eyes, I would have Proved; That they are Formed by the Watry Part of the Brain, and are the Contractive of it, Raiſed into the utmoſt Degree of the Expanſive; From whence they may be ſaid to be the Life and Spirit of it; and therefore that there is that particular Connexion betwixt the Temper and Conſtitution of the Brain and Eye, the Latter of which is ſaid to be the Index of the Former, and of the Mind and Underſtanding, which Reſides in it; Hence it is, that having ſo near an Alliance with the Brain, and conſequently with the Mind, it Communicates all the moſt Delicate Senſations to us; Whereas thoſe Perceptions, which we have from our other Senſes, whoſe Organs are leſs Nervous, and are Mixed with the Sanguineous Force, are of a Groſſer and Duller Information.

Whence their Life and Spirit and why They are Double as ſeveral other Parts of the Human Syſtem.

The Contractive of the Brain is Raiſed into this Spirit, or Expanſive, of the Eye by it's Conteſt with the Sanguineous Force (For it is owned by Anatomiſts to be ſurrounded with Muſcles, which have the Sanguineous Force in them, with which the Brain is not) and ſurmounting it, Starts out and Riſes into thoſe Fiery Balls, which give that Life and Beauty to the Animal Frame, and which Acquire, by that means, as Great a Degree of the Expanſive, as the Contractive of the Brain is capable of Receiving; Why they are Two, or the Noſtrils, or the Hands, or Feet, or why the Fingers are Five, and the Heart, Brain, and Mouth but One, Is to be Determined from the Courſe of the Nervous and Sanguineous Fluids in the Animal Syſtem, which, by what we have Recounted of Them, would not be Impoſſible to do.

What the Muſcles are, and whence the Difference of their Belly and Tendons.

In Reſpect of the Muſcles; The Belly of them Conſiſts of Nervous, and Sanguineous or Carnous, Fibres, by the Former of which they are Contracted, and Expanded by the Laſt, upon the Action of them from the Impulſe of the Mind on the Nervous Syſtem; and their Tendons are more Contractive by their Adheſion to the Bones, which are of a Contractive Nature, and to which they therefore Aſſimilate and Unite; but are kept Pliant by the Motion of the Muſcles, and their Vicinity to the Expanſive of the Sanguineous Part of Them; So that lying betwixt the Bone and the Belly of the Muſcle, they partake of a Middle Force betwixt both, being neither ſo Contractive as the one, nor ſo Expanſive as the other.

The Nature of Bones, and how they are Formed and Continued thro' the whole Syſtem.

The Bones are of a Contractive Force, and Ariſe from the Salts, or the moſt Contractive Parts, which are Separated from the Animal Compages, and are to the Marrow, and Aſſemble about it in order to Encloſe it, as the Nervous Subſtance is to the Expanſive of the Blood, which it Embraces; All the Difference is, that the Expanſive of the Blood is Quick, Agile, and Lively, whereas that of the Marrow, whoſe Subſtance will be afterwards ſhewn from it's Compoſition, is Flat, Heavy, and Languid: And therefore the Equal Balance is Preſerved in the Animal Syſtem by the Duller and Heavier Contractive in the Bones, and the Salts which Compoſe them, Acting againſt the Duller and Heavier Expanſive of the Marrow, which they Encloſe; In like Manner, as we have before Explained the *Æquilibrium*, in the ſame Syſtem, to be Maintained by the Contractive of the Quick and Nervous Fluid of the Brain, and the Expanſive of the Quick and Sanguineous Fluid of the Blood. Theſe Bones and this Marrow go thro' the whole Animal Frame upon the ſame Account, and for the ſame Reaſons, as the Nervous and Sanguineous Fluids do, which have been before Explained.

What the Marrow is.

The Marrow ſeems to be a Mixture, as Fat is, of the Contractive of the Nervous Force by the Nerves, which are ſent into it, and of the Expanſive of the Sanguineous by the Blood-Veſſels, which are Diſperſed in it; by which Mixture it is plain, that the Expanſive Force is much Diminiſhed by the Contractive of the Nerves, and that it is leſs Inflammable than Fat or Oil, by the Salts, and the Greateſt Contractive Force of the Bones, which Surrounds it.

I would have Enlarged more particularly upon theſe Subjects, but the Philoſophers and Anatomiſts being in a Different Way of Thinking, I ſhall Satisfy my ſelf with what I have Propoſed to them, and only take Notice of Two Things more, Wakeing and Sleeping, and the Paſſions of the Mind.

Of Wakeing and Sleeping. Dr. Cheyne's Eſſay on Health and Long Life.

As to Wakeing and Sleeping; Wakeing appears to be Derived from an Exceſs in the Contractive Force of the Nervous Syſtem, and the Expanſive of the Mind Acting upon it, the Latter of which Excites the Former into an Elaſticity or Springineſs, and is the Cauſe and Occaſion of all the Actions of Life, and the many Motions and the Varieties of them obſervable in it; Hence Perſons, who are Studious, and whoſe Mind and Nerves are Employed, are the moſt Wakeful; As alſo from a Defect in the Expanſive of the Sanguineous, from whence Perſons, who are the Leaſt Repleniſhed with Blood, and who want the Neceſſaries of Life, are the Leaſt Diſpoſed to Doſeing and Slumbers: On the other Hand, Sleep is owing to an Exceſs in the Expanſive Force of the Sanguineous Syſtem, when the Mind and Nerves are Paſſive; or to a Defect in the Contractive of the Nervous; Thus the Voluptuous and the Ideot are alike Inclined to Sleeping.

Why we are Taller when we Riſe, than when we go to Bed. Mr. Waſſe of Ayno, and Mr. Profeſſor Smith of Cambridge.

And from this Doctrine it will follow, what has been a late Obſervation of Philoſophers, that we are Taller by ſome Parts of an Inch, when we Riſe, than when we go to Bed, and I would Venture to ſay, tho' not Obſerved, Thicker and Plumper; Becauſe, as we have before Aſſerted, In Sleep the Expanſive Force moſt Prevails, which Dilates and Diſtends all the Dimenſions of the Body; But when we Wake, the Contractive, which Compreſſes and Conſtringes them. And thus by Sleep Men Grow Fat and Diſtended, and Lean and Contracted by Watching.

Why there is a Viciſſitude of Sleeping and Wakeing in the Animal Frame.

It muſt be alſo ſaid, That this Viciſſitude of Sleeping and Wakeing is a certain Sign and Indication of theſe Two Oppoſite Forces Exiſting in our Natures, and that there is a continual Conteſt betwixt them, by which ſometimes the one and ſometimes the other Prevails, till the Contractive at length ſubdues the Expanſive, the Animal Flame is Extinguiſhed, the Soul Flies off, and Death Enſues.

Why the Paſſions are of Two Oppoſite Kinds, and are to be wholly Suppreſſed, or Indulged in their Turns.

As to the Paſſions, They are all Reſolvible into thoſe, which are of an Expanſive and Contractive Nature, and, to Preſerve the Animal *Æquilibrium*, are to be Entirely Suppreſſed as much as Poſſible, or to be Indulged in their Turns in a Moderate Degree; If a Man were always to Grieve, or always to be Joyous, he would make his Frame Sink by the Contractive Force of the one Paſſion, or Diſſipate and Diſſolve it by the Expanſive of the other, and the Like may be ſaid of the Reſt.

CHAP.

CHAP. IX.

Concerning the Expanſive and Contractive Forces.

§. 1. WE have hitherto made all Nature to Conſiſt in Thought and Intelligence, or Action, for all that we Experience or find in it, is either Thought and Intelligence, or Matter, which we Affirm to be nothing elſe than Action; This therefore we ſhall ſtill farther Explain in this Chapter.

That Matter Conſiſts of Nothing elſe but Action.

THAT the Parts of Matter are Actuated by Various Motions is owned by the Preſent Philoſophy, but it is fancied, that the Parts of Matter themſelves are Solid, Maſſy, and Impenetrable, that they are Quieſcent, and only the Seats of Action, which may be Imparted and Communicated to them, whilſt they have an Abſolute Inertia in their own Nature; On the Contrary we cannot but be Perſuaded, that this Opinion of Matter is a Creature and an Abſtraction of the Mind, whereas in Truth, and in Fact, It appears to be nothing but Action it ſelf: Thus in Fire, for Inſtance, or in the Sun, our Perceptions from Either are thoſe of Light, Heat, and Colour, which are Evident Proofs of the Action of Both; and if we go farther than our Perceptions, by which we can only Judge of the Nature of Things, and will Aſſert, that this Action Proceeds from Solid Parts, which are Agitated, we mix Preſumptions and Imaginations of our own with our real Senſations and our undoubted Experiences; For from them, All that we can juſtly Conclude concerning thoſe Subſtances, is the Action of Them.

An Inſtance in Fire, and the Sun, or the moſt Fluid Bodies.

LET us now take a Solid, Heavy, and Reſiſting Body, as Gold, we Perceive it oppoſes our Hand Endeavouring to Penetrate into it; It Gravitates upon it, when Suſtained by it; and the Eye is ſenſible of it's Brightneſs and Yellow, which are likewiſe Inſtances and plain Indications of it's Action; and what we Experience from a whole Globe of it, we are convinced belongs to every the Minuteſt Particle, which can poſſibly fall under the Cognizance of our Senſes; If yet we are Reſolved to make this Subſtance conſiſt of ſmall Solid and unactive Particles, we depart from Nature to our own Fancies, and from Experience to Imagination, and Introduce into Matter and Bodies, what we never Actually found in Them; but if we will Adhere to Fact, and Regulate our Notions by our Informations from Material Beings, we ſhall then Confeſs, that they furniſh us with no other, than what manifeſtly Evince nothing more than the Action of Them.

Another Inſtance in Gold, or the moſt Solid and Compact ones.

IF any one ſhall ſay, that mere Action is Inconceivable without ſome Solid Subſtance to ſupport ſuch Action, and in which it ſhould Inhere; That only Proceeds from our being Uſed to conſider Things in the Corpuſcular Way, which has continually Inculcated to us it's Atoms or Particles, and the Moving of Them, and to our Obſervations of Groſſer Bodies Moving in Nature, which Bodies we have Conceived to be Solid and Unactive in Themſelves, without Conſidering, that even They Conſiſt of nothing elſe but Action.

Why we are Apt to Imagine, that Action in Matter muſt have ſome Solid, Unactive Subſtance to ſupport it.

§. 2. THIS Action we have alſo ſaid is Diſtinguiſh'd into the Expanſive and Contractive Forces, which, and the Different Combinations of them, are the occaſion of thoſe Diverſities of Matter, which we Feel and See to Exiſt in Like and Equal Portions of Space; Thus an Infiniteſima of Fire, which has no Pores or Vacuities in it, ſhall be Different from an Infiniteſima of Gold or Lead, and an Infiniteſima of Gold or Lead ſhall be Different from that of Water, or Wood, or Stone, which has likewiſe no Pores or Vacuities in it; And any Equal Globes Compoſed of ſuch Infiniteſima's ſhall be alſo Different from the Various Mixtures of theſe Forces.

The Various Kinds of Matter Ariſe from Different Degrees of the Expanſive and Contractive Forces.

§. 3. WHAT we mean by an Expanſive Force is an Action, which is Similar and Homogeneous in any Body, either in the Whole or in it's Parts, and which Exerts it ſelf Equably from a Center every Way; For Example, let us take a Globe of Fire, or that Immenſe one of the Sun, we ſuppoſe the Exertion of ſuch a Body to be outwards, not by an Actual Motion, but by a Force, which Endeavours to Dilate and Expand it ſelf every way from the Space, in which it Reſides, and that every Point in the ſame Globe has a like Property and Affection of Exerting it ſelf from thence in

The Expanſive Force Explained.

the ſame Manner, ſo that the Action of the Whole, and of every Part, is Entirely Similar and Homogeneous.

THAT the Sun, or Fire, has this Expanſive Force of Exerting it ſelf from a Center, or ſeveral ones, that is outwards, is Evident from our Feeling, and it's Burning Quality, by which it Diſſolves the Nerves, the Inſtruments of our Senſations, Cauſes Bliſters, Diſſipates Clouds and Vapours, Raiſes and Elevates Water into the Air, and Rends and Tears in Pieces Wood, and other Inflammable Subſtances, and even Metals by the Fuſion of them; and that every Particle of Fire has, in Proportion to it's Quantity, the ſame Force, we know by the leaſt Spark of it Burning and Diſſipateing the ſame Way.

The Contractive Force Explained.

§. 4. ON the other Hand, what we mean by a Contractive Force is an Action, which is Similar and Homogeneous in any Body, either in the Whole, or in it's Parts, and which Contracts it ſelf Equably to a Center, or Centers, from all Sides; For Example, the moſt Solid and Compact, and the Coldeſt Body we can mention or ſuppoſe, as the Moon, or the moſt Metallick Ice we are capable of Imagining, or this Earth we Inhabit.

THAT the Moon has this Contractive Force is plain from the Tides it occaſions, by which the Waters Tend towards it; That the Earth likewiſe has, is as manifeſt from Heavy Bodies Gravitating to it; and That Solid and Compact Subſtances are Endued with the ſame Power, is Notorious from the Difficulty we find in Separating or Dividing of them; That they feel Cold to us, Proceeds from the ſame Cauſe; For as Heat Diſſolves, Cold Contracts our Nerves, the Inſtruments of our Senſations; As Heat Diſſipates and Diſunites Material Beings, Cold Hardens and Cements them; Which are all Inſtances of a Force Acting Inwards, and towards a Center, or Centers; And as every Particle of theſe Bodies has, in Proportion to the Quantity of it, the ſame Influence and Effect, it is Reaſonable to Conclude, it has the ſame kind of Force with the Whole, that is, ſuch a Contractive one, as we have been Deſcribing.

How the Expanſive and Contractive Forces may be Communicated to Bodies, which ſurround them.

§. 5. How the Expanſive Force Exerts it ſelf Outwards, and makes it's Impreſſions upon all Bodies, which come within the Sphere of it's Activity, is Conceivable enough, that is, how a Fire, or the Sun, ſhould by it's Exertion thro' the Plenum communicate it's Force to it, and the Beings which Exiſt in it, and by that means either Heat or Burn them; But how the Contractive Force ſhould obtain any Effect External to it, whilſt it's Action is ſuppoſed to be Inwards, and towards a Center, or Centers, may be difficult to Apprehend; Thus, how the Earth, which has a Contractive Force, ſhould cauſe Bodies to Deſcend to it, and the Moon, the Waters to be Raiſed and Elevated from it; But this will Admit of an Eaſy Solution, if we Conſider, that a Contractive Force has the Nature of an Expanſive, only Acting from a Different Center, and in a contrary Direction; What therefore any Expanſive Force can Produce or Effect, in a Plenum of Matter, by a Progreſſion into it or a Repulſion of it, a like Influence will a Contractive Force have by a Regreſſion from it, or an Attraction of it.

The Reaſon of the Preſent Conſtitution of the Univerſe, and why the Sun and Stars, and Planets are Placed at that Immenſe Diſtance from each other.

HENCE it is, that there is ſuch an Immenſe Diſtance betwixt the Sun and the Planets; becauſe the Sun by it's Expanſive Force Reduces all Material Beings to it's own Action, or elſe Repells them from it, the Intermediate Æther being ſubject to it's Impreſſions of Light and Heat; Whilſt the Planets on the Contrary, Preſerving their Contractive Force, Recede from the ſame Medium Inwards, into which the Sun Expands it ſelf, and Attract and Draw the Plenum, and all other Bodies, towards them.

The Difference betwixt Air and Æther, and why the Former is Elaſtick.

How the Forces of Nature, the Expanſive and Contractive, are Analogous to the Poſitive

ANOTHER Reaſon of this Conſtitution of the Univerſe is, that Forces of the ſame Nature Tend to each other, from whence, all, which is of an Expanſive Force, as Fire, Unites with the Sun and Stars, and what is of a Contractive one, with the Earth and the Planets of each Syſtem; By which likewiſe that Immenſe Intervall of Æther, which is of the ſubtileſt Matter, is cauſed, having neither the Expanſive of the Sun, nor the Contractive of the Planets, but being Obedient to either, as their ſeveral and particular Forces Prevail; Air on the other Hand has an Elaſtick Force, from the Expanſive of the Sun Mixing with the Contractive of the Earth, by which upon Compreſſion it is Dilated, and Vibrates upon Percuſſion; And from a Conteſt betwixt the Expanſive of the Sun and the Contractive of the Planets, as we have before ſaid, the Revolutions of the Latter about the Former are Produced and Made. And this Account of theſe Two Forces is Juſtified by all the Quantities, which we know, or have been hitherto Propoſed in Nature or in the Mathematicks, which are either

Negative or Poſitive, that is, Regreſſive or Progreſſive, Expreſſed by $-$ or $+$, and which have Equally their Abſolute Effects in the Ratio, or Reaſon, of Things, which is Evident in all Algebraick Demonſtrations, as we have ſhewn they have in Nature.

and Privative Quantities of Mathematicks and Algebra.

§. 6. In Reſpect of theſe Expanſive and Contractive Forces, it may be farther Inquired, how they are Communicated, and which way, and by what means they Prevail; To which, it is Anſwered, that the Expanſive Force, for Inſtance, of Fire Prevails by Turning and Converting every Thing into it's own Expanſive Force or Action; Thus a Spark is Kindled into a Flame, and one Portion of Fire or Flame Unites to Another.

The Mechanical way by which the Expanſive and Contractive Forces are Propagated and Increaſed.

THE Firſt may be eaſily Conceived; For a Spark Exerting it ſelf every way from a Center, if it meets with a Contractive Force, as of Stone, which it cannot Subdue, it is Extinguiſh'd and Dies, but if with a Light and Expanſive Subſtance, upon which it can make it's Impreſſions, as Tinder, or Linnen Burnt, it Communicates it's Force, in the ſame Manner, as Motion is Produced by Impulſe, and the Effect, in both Caſes, Partakes of the Nature of the Cauſe; And by the ſame Method this Aſſemblage of the Expanſive Force will Impart it's ſelf to what elſe is Inflammable, by Impreſſing it's own Action upon it, and Converting it into it, till a Flame is Raiſed ſufficient to Promote the like Force to what Degree, or as far as, we Pleaſe.

THE Second, how one Expanſive Force Unites with another, is alſo Evident from the above-mentioned Explanation, if thoſe Forces are Contiguous; for if the Expanſive Force Reduces, as far as Poſſible, what is Contrary to it, to it's own Action, it cannot but Cement, and Concur, with it's own, for that very Reaſon; if they are not Contiguous, they muſt be either Hindered from Uniteing by Contrary Forces, which they cannot Overcome, or they will Overcome thoſe Forces by Impreſſing their own Action upon them, till they do Unite.

FROM hence it is, That if we take Two Lamps, or Candles, and ſet them a-Burning at ſome Diſtance from each other, they will Riſe in Diſtinct Flames in a Conical or Pyramidal Form; Becauſe they Exert themſelves in an Oppoſite Direction by their Expanſive Force to the Contractive of the Earth, and the Medium of Air, or the Atmoſphere, which Tends towards it; and the Flame grows Pointed at Top, becauſe the Expanſive Force is there Leſs, and the Contractive of the Air or Atmoſphere, in Reſpect of it, Greater; But if we place theſe Flames in a nearer Situation to each other, they will on the Sides of them manifeſtly come together, and endeavour at an Union. And thus in Fire, the Fuel at firſt Separates it into Different Flames, till at length the whole Receives the Action of the Expanſive Impreſſed upon it, and the ſeveral Expanſive Forces are United into one.

Why the Flames of Two Lamps or Candles Riſe in a Pyramidal Form, and when Set together Unite on their Sides.

THAT therefore Forces of the ſame kind Tend to one another, It is Plain is not by an occult Quality, but by the Method, by which all Motions are Communicated to Material Beings; and there is no more difficulty in Conceiving, how an Expanſive Force ſhould Produce an Expanſive, than how an Impulſe from the Hand ſhould Produce Action or Motion in Body, the Effect is Anſwerable to the Cauſe, and Follows, and Participates of, it's Nature; And we have ſhewn, Granting this Principle only, that it is eaſy to Account for a Tendency to an Union of the ſame Forces.

The Uniteing of Similar Forces is not by an occult Quality, but by the known and confeſſed Laws of Mechaniſm.

WHAT we have ſaid of the Expanſive Force is Equally Applicable to the Contractive, ſince they Differ, not in Force, but in the Direction of it, and therefore a Contractive Force will Impreſs the ſame Force upon Bodies, which are not, as Fire, too Expanſive to be overcome or ſubdued by it; Thus the Contractive Force of the Earth and the Moon, where the Expanſive of the Sun is not too Predominant, will Turn Water into Ice, and Earth into Metals, Minerals, and Stones, which are all therefore Formed in the Inward and Subterraneous Receſſes of our Planet; and it is not Certain, ſince we can only Penetrate a few Yards of Four Thouſand Miles, of which the Semidiameter of the Earth nearly Conſiſts, but there may be Subſtances of a much Greater Contractive Force than any we meet with juſt under the Surface of it.

How Water is Turned into Ice, and Earth into Metals, Minerals, and Stones; and that there may be more Compact and Solid Bodies near the Center of the Earth, than any we find near the Surface of it.

AND for the ſame Reaſon Heavy and Compact Bodies Deſcend to the Earth, which have a Contractive Force, becauſe they will be either Hindered by ſome Oppoſite Expanſive Force, which they cannot Surmount, or elſe they will Reduce that Force by their Contractive, till they are United and Cemented with that of the Earth, which is of the ſame Kind and Species of Action with Them.

Why ſome Bodies Deſcend to the Earth, and others Aſcend from it.

Thus Heavy Bodies are Actually Hindered from Deſcending by the Expanſive of Fire, but otherwiſe Unite with and Precipitate to the Earth, As in Smoke and Vapours.

That there is no Determined Center of theſe Expanſive and Contractive Forces, and therefore none of the Earth or Sun.

§. 7. Since therefore theſe Expanſive and Contractive Forces conſiſt in a Similarity or Likeneſs of Action, tho' the one Exerts it ſelf from a Center, and the other towards one, yet it cannot be ſaid, that ſuch Centers are any fixed or determined Points, becauſe the Whole and Every Part of theſe Expanſive and Contractive Forces are Homogeneous; and conſequently, when we ſay, that Bodies, as the Planets, are Repelled from the Sun by this Expanſive Force, we do not mean, that they Recede from the Exact Center of it, or when we Affirm, that Bodies Deſcend to the Earth, do we Intend to ſay, that they do not Deſcend to the whole Maſs of it's Contractive Force, without any Diſtinction of a particular Center belonging to it; On the Contrary it ſeems Plain, that the Sun is to be Conſidered as an Aſſemblage of the Expanſive Force, without any particular Center of it's Action, and that the Earth is to be looked upon, as a Congeries of the Contractive, without any ſuch certain Point to which the Contraction is made; For no One ever Dreamed of ſuch a Center in a Fire, or a Flame, or of ſuch a Point in Amber, or the Load-ſtone.

As to the Firſt, all the Reaſon, which can be given for it, is only, that the Planets Revolve round it, as if there were ſome Fixed and Determined Center of it; But it is known, there is ſuch an Immenſe Diſtance betwixt It and Them, that the whole Body of the Sun bears no Great Proportion to ſuch a Diſtance; Beſides, the moſt Accurate Account of the Revolutions of the Planets ſuppoſes, there is no ſuch fixed Center in the Sun, the Common Center of Gravity of all the Planets, tho' Quieſcent, yet by the Agitation of the Sun, being ſometimes in it's Surface, and at other Times, a little Above or Below it; which may be owing to what we Affirm, that the Sun really has no Center, and that the whole Body of It is to be Eſteemed, as one Maſs of the ſame Similar and Homogeneous Action.

Sir Iſ. Newt. Princip. Math. Philoſ. Natur. Prop. 12. Lib. 3.

As to the Second, the Spherical Surface of the Waters in the Ocean is Imagined to be an Argument of it, which may be as Rationally Explained by ſuppoſing the Earth is nearly Globular, which is Confeſſed, and that the Contractive Force of it being of that Figure Preſcribes the ſame to the Waters, which manifeſtly obey the Impreſſions it gives, as we have ſhewn they do in the Tides, in the Regulating of which the Earth has it's Influence, as well as the Sun and Moon.

See Chap. 5. Book 1. §. 22, 23, &c.

What is the Reſult of Two Equal or Unequal Expanſive or Contractive Forces mixed together, and how from thence the Phænomenons of Fluids or Solids upon their Mixture are Solved.

§. 8. From this Explication of the Expanſive and Contractive Forces it follows,

First, That each Expanſive Force, or each Contractive Force, Conſidered by it ſelf, has it's Center of Action every where, and Acts Uniformly from, or towards, it's ſeveral Centers; Thus Fire Acts outward in the whole Maſs of it, and in every Part of that Maſs; Heavy and Compact Bodies Act Inwards, in the Whole, and in every Part of the Whole.

Second, That Bodies, or the Parts of them, which have the ſame Expanſive or Contractive Force, are in an Equal Poiſe and Balance, and therefore at Reſt amongſt themſelves; Thus Solids, and the moſt Fiery and Spirituous Fluids, are alike Quieſcent.

Third, That if Two Expanſive or Two Contractive Forces, that is, which Act to or from the ſame Center or Centers, are Equal, and there is an Addition of the one to the other, namely, of the Expanſive to the Expanſive, or the Contractive to the Contractive, there will be no Alteration Produced in the Degrees of the ſeveral Forces; becauſe the Actions will be Similar and Homogeneous, and therefore in an Equal Poiſe or Balance, by Article the Second; And hence it is, that Fiery and Spirituous Fluids mixed with Fiery and Spirituous ones of the ſame Nature, or Solids with Solids, as Gold with Gold by Fuſion, continue the ſame.

Fourth, That if Two Expanſive Forces are Unequal, and the one is Blended or Mixed with the other, the Greater will Increaſe the Leſs, but not a Leſs, a Greater; For Inſtance, if an Expanſive Force Acts from a Center with a Force of Two, and another from the ſame Center with a Force of Five, the Force of Two on both Hands will be Equal, and ſo far Similar and Homogeneous, and therefore, by Article the Third, there will be no Alteration Produced; but the Force of Five Exerting it ſelf ſtill with an Exceſs of Three, ſuch Point or Center will be Acted by that Impreſſion, and what is ſaid of one Point or Center, holds Good in all of the ſame Bodies, which have the ſame Nature and Similarity of Action.

FROM hence it is, that the Expanſive Force of Fire or Flame, Mixing with a Greater or Leſs Expanſive Force of Oil, or Fuel, and the Different kinds of it, becomes more or leſs Vigorous in it's Action or Force; And from the ſame Cauſe it is, that if we mix a more Fiery or Spirituous Fluid with a Leſs, as Spirit of Wine with Water, the Expanſive Force of the Water is Increaſed, and that of the Spirit of Wine is Diminiſhed.

LIKEWISE, If Two Contractive Forces, which Tend towards the ſame Point or Center of Action, are Unequal and Compounded together, the Caſe will be the ſame, as before in the Expanſive, that is, the Forces will be in an Æquilibrium, ſo far as they are Equal, and the Exceſs of the Greater Contractive Force above the Leſs will only cauſe an Alteration.

FROM hence it is, That Gold mixed with Silver or Copper in Fuſion loſes of it's Weight, and Silver or Copper Receives an Addition to it, and ſo in other Metals, where an Heavier and a Lighter are Fuſed together.

Why ſome Fluids are more Eaſily, and ſome Solids more Difficultly, Separated than others; and why they have Inclinations and Tendencies to and from the Earth Different from thoſe of their Parts to each other.

§. 9. AND from this Doctrine of the Expanſive and Contractive Forces we are alſo Informed, why the Parts of ſome Fluids are more eaſily Separated, and the Parts of ſome Solids more Difficultly, than thoſe of others; Becauſe, in the Former Caſe, the more Expanſive any Fluid is, the more Eaſy is the Separation of it, and in the Latter, the more Contractive any Solid is, the more Difficult is ſuch Separation.

IT muſt be here Obſerved, in Reſpect of the Expanſive and Contractive Forces of Bodies, that they are not always Equal to their Expanſive from the Earth, or their Contractive to it; Thus the Expanſive Force of Spirit of Nitre, and Oil of Vitriol, is very Conſiderable in it's Diſſolving of Metals, which Fire or Flame cannot do, and yet Fire or Flame Recedes from the Earth, whilſt the Spirit and Oil Gravitates towards it; On the other Hand, Gold Gravitates more, or has a Greater Contractive Force towards the Earth, than a Ruby or a Diamond, and yet the Parts of the Latter have a Greater Contractive Force to each other, than the Former; The Reaſon of which is, becauſe Fire and Flame are Entirely of an Expanſive Nature, whereas Nitre and Vitriol are originally of a Contractive one, and are made Expanſive by the Force of Fire, and therefore Retaining ſtill a Degree of their original Contractive, they Gravitate to the Earth, tho' Exalted into Spirit and Oil; Thus alſo Gold Gravitates more, or has a Greater Contractive Force towards the Earth, than a Ruby or a Diamond; Becauſe the Firſt is Formed in the Bowels of it, and in the Midſt of the Contractive Forces, as all other Metals are, and in Colder Countries and Climates, whereas the Latter are Produced nearer to the Surface of the Earth, where the Contractive does not ſo much Prevail, and in Hotter and Warmer Climates; But Gold is more eaſily Separated, is more Fuſible and Ductile, than the others; Becauſe the Expanſive Force has Exerted it ſelf to the utmoſt in the Formation of the Latter, and yet their Contractive Force continues, whereas there has been but a ſmall Expanſive Force, in Compariſon, Applied to the Production of the Former, and therefore, when a Greater Supervenes, it is Diſſolved or Separated in the Parts of it; For ſo Earth and Clay, tho' they are eaſily Separated, yet have an Intenſe Force of Gravitation, whereas Glaſs and Chryſtal, which are made by Fire and of Flint, are with Difficulty, tho' they have a Leſs Force of Contraction or Gravitation to the Earth; Another Reaſon may be, that Gold and Metals are poſſibly Formed from Quick-ſilver, which is ſaid to be *Mater Metallorum*, the Volatility of which will make the Metals, which are Fixed and Produc'd from it, more eaſily Separated, tho' their Contractive Force to the Earth may not be Diminiſh'd, but Increaſed.

THIS therefore will lead us to Enquire, what Effects will Ariſe from a Mixture of the Expanſive and Contractive Forces.

An Inertia Produced from Equal Degrees of the Expanſive and Contractive Forces, and what Æther, Air, and Water are.

§. 10. IF Two Forces are Equal, the one an Expanſive, and the other a Contractive, They muſt upon their Application to each other, like + and − in Algebraick Quantities, and in the Motions of Bodies, Deſtroy each others Effects; For if one Force Exerts it ſelf from a Point, and another towards the ſame Point, the Conſequence will be a Quieſcence or Inaction, or Nothing in Reſpect of an Expanſive or Contractive Force; and a Syſtem of Matter, which is Compounded of ſuch Forces, muſt be Endued with an entire Inertia, and be Paſſive to any External Impreſſions; There does not ſeem to be any Material Being, which comes ſo near to this Compoſition, as the Corporeal Space, or the Æthereal Plenum, which Surrounds us; It is Colourleſs and Tranſparent, and has no Heat in it ſelf, and therefore has little or no Expanſive Force to Produce the Senſation of Colour or Heat in us; It has an Inſenſible Gravitation, and is eaſily Separated in it's Parts by our Moving in it, and Dividing it by the leaſt Percuſſion, and therefore is void of any Apparent Contractive Force, and conſequently is capable, by this Inertia, of Receiving and Obeying any Foreign Impulſe; It is alſo Conſtituted and Formed by the Expanſive Force of the Sun, and the Contractive of the Earth, which we may reaſonably Imagine are here nearly in an Equal Balance, ſince otherwiſe the Expanſive Force of the Sun, if Superior, would Repell the Earth farther from it, or, if Inferior, the Contractive of the Earth, would Approach nearer to it, till it had Strength and Force enough to Repell it.

Air and Water are the next Material Beings, which come the neareſt to this Conſtitution of Forces, by their want of Colour, Heat, and Activity, and their Defect in Gravitation and Contraction, by which almoſt all Bodies Sink and Gravitate in them, and by which they eaſily yield to any Impreſſion, or become Fluid; but theſe yet have certain Forces of Expanſion and Contraction belonging to them, by which they ſhew their Forces are not in an Exact Æquilibrium, as is Evident from their Elaſticity, Colour, and Power of Diſſolving Bodies on the one Hand, and their Re-union of Parts, upon their being Separated, and their Gravitation, on the other.

Other Fluids alſo by their Colour, and their Spirituous Qualities, and their Power of Diſſolving Bodies, manifeſtly declare their Expanſive Force, and by the Aſſemblage of their Parts to each other, and by their Gravitation, their Contractive, and that they are not in an Equal Balance; Solids, in like manner, Evince, that by their Colour they have a plain Expanſive, and by the cloſe Cement of their Parts, a Contractive one, and that they are not in an Æquilibrium.

An Inertia Various in Different Bodies, and the occaſion of Fluidity.

§. 11. But it deſerves to be Enquired, whether theſe Equal and Expanſive Forces, however Different, Acting againſt each other, will Produce the ſame Quieſcence or Inertia, which it does not Appear, that they will, ſince, where the Cauſes are Different, the Effects muſt be ſo too; Thus let us take a Leſſer Expanſive Force of the Sun's Rays, and a Leſſer Contractive of Earthy Matter, and the Fluidity of Æther, or Air, or Water, is Produced; if we take a Greater Expanſive Force of the Sun's Rays, as in a Burning Convex or Concave, and a Greater Contractive, as of Gold, the Fluidity or Fuſion of it is cauſed; and yet the Fluidity, or Inertia, or Quieſcence of the one, is not Equal to that of the other; Thus alſo, if Two Bodies meet with Equal Forces, which are Leſſer, and other Two meet with thoſe which are Greater, tho' there is an Equal Deſtruction of their oppoſite Forces, yet the Effect or the Reſult on both Hands is not Equal, for it will be eaſier to Separate them in the Firſt Caſe, than in the Laſt; And it is the ſame even in Mathematical Quantities, for tho' $a-x$ is $=0$, and $b-z=0$, it will not be immediately Conſequent, that $a-x$ is $=b-z$, no more than a is $=b$; for there may be as many various Noughts, as there may be Infinites, and which are Different according to the Different Quantities, from which the Relations of Infinite and Nought are Derived, as a Nought or an Infiniteſima of a Cube or a Surſolid is not Equal to that of a Line or a Square; but if we mean by $+$ and $-$ an Affirmation and Negation of the ſame Thing, it is an Abſtracted Idea, and do's not deſerve to be conſidered in Nature or in Real Quantities. For, as in the Inſtance of Two Concurring Bodies before, if I preſs my Two Hands together with an Equal and a Contrary Force, and then with an Equal and Contrary Force, yet Double or Triple of the Former, it will not, I hope, be ſaid that the Effect in both Caſes is Equal, tho' there is a like Deſtruction of the Contranitent Forces.

Whence Volatility and Coheſion, Mobility and Diviſibility.

§. 12. If now Two Forces are Unequal and Act contrary to each other from a Point, (and that which is the Caſe of one Point, will be the Caſe of an Hundred or a Million, which are ſuppoſed to have the ſame Conditions in a Syſtem of them, that is, in any Material Being) what will be the Effect? Namely, That ſo far as they are in an Equal Balance, a Different Fluidity would be Produced, that is, a Leſs or Greater, as the Equal Forces are Greater or Leſs, according to what we have before Explained; But ſo far as the Expanſive is Superior, that Fluidity will be changed into Fire and Volatility, and ſo far as the Contractive is, into Solidity and Coheſion.

Let us in the Firſt Place Examine into Fluids, Æther we have already Mentioned and Endeavoured to Account for; Wine and other Spirituous Fluids, are Fluid by an Equal Balance of their Expanſive and Contractive, but are Spirituous by their Expanſive; And this Spirit is Lighter or Heavier, as the Expanſive is Greater, which Actuates the Contractive, and the Contractive is Leſs, or as the Contractive is Greater, which is Actuated, and the Expanſive is Leſs; ſo that every Spirituous Fluid is a Contractive Force Acted by a Superior Expanſive, which Contractive, as it is Different gives likewiſe a Different Moment and Impreſſion to the Expanſive; and from hence ariſes the Different Spirituouſneſs of Water, Wine, Brandy, Alcohol, *&c.*

On the Contrary, Solids proceed from a Prevalence of the Contractive over the Expanſive, by which it Curbs and Reſtrains it from Exerting it's full Force and Energy, and preſcribes it's own Bounds and Limits to it's Action, but tho' the Contractive Prevails the Expanſive is mixed with it, and gives a Different Impreſſion and Moment to the Contractive, as the Contractive did before to the Expanſive; And from hence it is, that the Expanſive of Solid Bodies Exerts it ſelf only on and within the Surface of the Solid, and by it's Impulſes upon the Æther occaſions the Various Senſations of Colour, which we Receive from them, when the Æther is Excited by the Sun's Expanſive, and rendered ſuſceptible of ſuch Minute Agitations of it; Sometimes alſo the Expanſive, notwithſtanding the Contractive, continues ſo Vigorous and Strong, as to Raiſe the Senſations of Smell in us, as in Odorous Bodies; And in General, the Capacity of Bodies being moved by the Expanſive Force of Percuſſion, Ariſes from this Mixture of the Expanſive in all Bodies, as likewiſe their Capacity of being Separated and Divided; for if the Contractive Force was Infinite in the one Caſe or the other, it would be Impoſſible, that Bodies ſhould be either Moveable or Diviſible.

§. 13. The Source and Origine of theſe Forces in all Material Beings, which we know, is the Sun, or Fire, or Heat, namely, of the Expanſive, and the Earth, the Moon, and the Planets, or Cold and Salts, of the Contractive; ſo that we may truly Affirm, that all the Various Portions of Matter are Compounded of Infinitely Various Degrees, and Various Combinations, of Heat and Cold, Mixed and Tempered together.

The Source and Origine of the Expanſive and Contractive Forces, and the Method of their Acting upon each other.

And the Method of Acting of theſe Forces one upon another ſeems to be, that the Expanſive Aſſiſts and Promotes the Expanſive, and the Contractive the Contractive; Thus any Inflammable Subſtances, which have a good Proportion of the Expanſive Force in them, by the Application of the Expanſive of Fire or Flame are eaſily Reduc'd to an Expanſive, and Cold and Contractive Bodies, and which are not Inflammable, as Water and Earth, by the Application of a Contractive, to Froſt and Ice.

On the other Hand, the Expanſive Acting upon a Contractive, if not Superior to it, Increaſes the Contractive, and a Contractive Acting upon an Expanſive, if not Superior, Increaſes the Expanſive; Thus Fire Increaſes the Weight of Lead in Calcining, and that of other Contractive Bodies, Water grows Colder for being Boiled, and thus we may Imagine that Mercury by a Heat, which would not Diſſipate it, that is, by a Gentle one, would grow Fixed and Heavier, that is, that Gold might be from thence Produced; On the Contrary, Water, thrown upon the Fire, if not in too great a Quantity, or a Froſty Air, makes it burn the Fiercer, and Water poured upon Quick-Lime cauſes an Intenſe Heat, and an Acid upon an Alkali an Efferveſcence: The Reaſon of which appears to be Plain, that as one Force will Act in Conjunction with another Force of the ſame kind, ſo Two contrary Forces will Act, as much as Poſſible, in Oppoſition to each other.

How Gold may poſſibly be Produced. See alſo §. 32. Chap. 3. Book 1.

§. 14. We ſhall not therefore now Enlarge any farther upon theſe Forces, to ſhew the Great Advantage there is from them in Explaining all the Effects we obſerve in Being, only Conclude by Saying, That they will much better ſerve that Purpoſe than any Principles, which have been hitherto Propoſed by the Defenders of *Epicurus*'s Syſtem of a Similar and Homogeneous Matter, it's Atoms and the Gravity of them; and, That there is an Eaſy Solution given of the Coheſion of Matter, and how there may be Different Conſtipations of it in the ſame Space, namely, from the Various Combinations of Action in it; Neither of which Problems are in any Meaſure Accounted for by the *Epicurean* Scheme, and the Atoms with their Gravity, which it Aſſerts, and which It Thinks to juſtify by Intricate Propoſitions, and Demonſtrations,

Theſe Principles more Univerſal and Extenſive than the Corpuſcular.

in the Mathematicks, which have no Relation to the Point in Queſtion, and which ſhew more the Sagacity and Penetration of the Geometer, than the Solid Reaſoning or Senſe of the Philoſopher, and of a Strict and Impartial Inquirer into Nature; The Circulation of which not only in the Heavens, which we have before Explained, but in our Sublunary World, is Owing to theſe Expanſive and Contractive Forces: For the Reaſon of Water and Earth Riſing into Plants, Trees, and Vapours, is Derived from the Expanſive of the Sun, and their falling Back again in Dew, Rain, and Leaves, is from the Contractive of the Earth; which Expanſive and Contractive Forces of the Sun and Earth, being nearly in an Æquilibrium on the Surface of the Latter, as above-mentioned, is the occaſion of thoſe continual Revolutions of Material Beings, which we Behold.

From theſe Principles the Exiſtence of an Infinite and All-wiſe Agent may be Immediately Concluded.

§. 15. WHAT we have more to do is to Evince, from theſe Principles, the Neceſſity of an Infinite and All-wiſe Agent, that, as we originally Propoſed, we may make the Demonſtration of a God the Reſult and Concluſion of all our Reſearches and Inquiries into Philoſophy; And what can be more Evident than that there is ſuch a Being, from the Principles, which we have laid Down?

IF there were an Infinite and All-wiſe Agent, of Conſequence we muſt ſuppoſe there would be an Infinite Action Produced from him, and that this Infinite Action would be ſo Adjuſted in the ſeveral Parts of it, as to Cauſe the moſt Regular Order and Diſpoſition of Things; On the Contrary, if we ſhew that this Infinite Action is ſo Adjuſted, we muſt be obliged to Acknowledge, that there is ſuch an Infinite and All-wiſe Agent.

AND Nothing can be more Evident than this; Since, notwithſtanding all the Infinite Variety of Forces, which are in their own Nature Contrary to each other, yet they are ſo Diſpoſed by the Infinite Wiſdom and Intelligence of the Almighty and Great Creator, as to Produce an Æquilibrium in the Whole, and an Harmony in all the Beings of the Univerſal Syſtem.

I Have not any Thing more at Preſent to Add in Reſpect of theſe Forces, Unleſs to Inform the World; That this Doctrine of the Expanſive and Contractive Forces was what I originally had a Notion of, before my Reading the Leaſt of what Sir *Iſ. Newton* has Advanced in his Mathematick Principles of Philoſophy; That I have Mentioned it, many Years ago, in my *Geometria Solidorum ſive Materiæ*, which was in Part Written by me, when I was Under-Graduate in this Univerſity; That I was not a little Pleaſed to find ſo Great a *Genius*, as Sir *Iſaac*, to Confirm my Sentiments in Reſpect of a Gravitating Force in Matter, which is a Species and Kind, or rather a Conſequence, of the Contractive, which I Maintain; and That what Firſt led me into theſe Opinions, was, that I found Different Appearances of Material Beings in the ſame Space, which could not be Accounted for by conſidering Matter, as conſiſting only of a Trine Dimenſion; I therefore Examined, as carefully as I could, what might be the Cauſe of ſuch Different Appearances, and could not Perceive, after the ſtricteſt Scrutiny, that it could be Attributed to any Thing elſe, Excepting to a Difference of Action; This Incited me to Inquire, what that Difference of Action was, which I could not but Acknowledge muſt have a contrary Direction, and could be Reſolved into nothing more Rational than an Expanſive and Contractive one: And, if to all this it ſhould be Objected, that I make Two contrary Actions to Exiſt in the ſame Space, I ſhall only Anſwer, that this we may Experience, if we Pleaſe, every Minute in our Lives, if we will but Preſs one Force againſt another in Oppoſite and Contrary Tendencies.

Geometria Solidorum ſive Materiæ. Pag. 15.

CHAP. X.

Concerning Pneumaticks and Hydroſtaticks, and a Real Space, or Extenſion, or of Air and Æther, and the ſeveral Kinds of Experiments made in Them.

The Difference betwixt Real and Abſtracted Extenſion.

§. 1. THAT Real Extenſion, or the Space, which Exiſts in Nature, has all the Properties of that Subſtance, which is called Matter, and beſides thoſe, ſome others peculiar to it ſelf, we ſhall in this Chapter ſhew; The Properties, which are Aſcribed to Matter in General, are theſe, *viz.* Extenſion, Impenetrability or a Non-Penetration of Dimenſions, Solidity or Reſiſtence or Firmneſs, Gravity, Mobility, and, as the Corpuſcular Philoſophy ſays, Figure and Diviſibility.

FIRST, As for the Extenſion of Space no one doubts of it, ſince Thoſe, who Defend a *Vacuum*, make it to conſiſt in nothing elſe; and Thoſe, who Maintain a *Plenum*, make it of the very Eſſence of Body; But in Both it is an Abſtracted Idea, as generally uſed by Them, and Similar according to that Idea; Whereas, as it Exiſts in Air, Æther, and ſeveral Parcels of Matter, that is, in Nature, it is very Different; One is Cloſer and more Compact, Another Thinner and Rarer, One Stronger and Firmer, Another Weaker and more Diluted, According to the Different Proportions of the Expanſive and Contractive Forces, Acting in the ſame Abſtracted or Similar Space.

Impenetrability of Two Kinds, the Firſt Abſtracted, the Second Real, and may be Admitted in Nature.

§. 2. SECOND, Impenetrability, or a Non-Penetration of Dimenſions, is likewiſe Acknowledged by both theſe Sects of Philoſophers in one Senſe, that Space cannot Penetrate Space, or that one Part of Space cannot Poſſeſs another at the ſame Time, that the other Poſſeſſes it; but on the Contrary it is Acknowledged, that tho' this cannot be, yet Body, which is Extended, may Poſſeſs Space, which is likewiſe confeſſed to be Extended, which Two Opinions we ſhall Conſider.

Sir If. Newt. Princip. Definit.

1*ſt.* THE *Primarius Locus*, as it is Termed, or Place, in it's Proper Signification, is thought to be Immoveable, and therefore cannot Enter into another Place; or if it was not Immoveable, if one Place could Penetrate another, Place would Exiſt in Place, and conſequently one of them only would be Primary, which is no more than to ſay, our Idea of one Part of Extenſion is not our Idea of another; For in Truth, Place, or the *Primarius Locus* is only a ſtanding Meaſure of Extenſion delineated in the Mind; It is an Abſtracted Idea, and nothing in Nature and Reallity; It is a determinate Image of Space made and ſhaped by the Mind, ſo as to Agree to any Body we are Willing to Conſider; The Reaſon of which Procedure of the Mind ſeems to be, that, not obſerving any Thing in Space, but Length, Breadth, and Depth, and finding no Reſiſtence in it to the Motion, or Dimenſions, of Body, and at the ſame Time, that all Space is in a perfect Repoſe, it from thence Concludes, that Body does Move in Space, and conſequently Poſſeſſes a Portion of it, agreeable to it's own Bulk; Another Reaſon is, our Perceiving Extenſion every where, without Conſidering the Real Properties and Affections, which belong to it, which leads us to Form our Notion of it's being Abſtracted and Similar; but what has Contributed the moſt to this are the Elements of Geometry, and the Abſtractions of Length, Breadth, and Depth Inculcated in them, we are therefore to Examine,

2*d.* WHETHER Body does Move in, or Poſſeſs Real Space, or, which is all one, Æther; We ſay not, no more than a Plumbet Moves in the very Dimenſions of Water.

1*ſt.* BECAUSE the Mind falſely Concludes, that there is neither Motion nor Reſiſtence in the Æther, or Real Space, for the Reaſon only that it Perceives none; Since the Senſes are very unequal Judges concerning a Matter ſo Refined and Subtile, that it muſt needs Eſcape them; Thus there is a Gravitation of one Body to another, which yet is not Perceptible, becauſe it is nothing in Compariſon with their Gravitation to the Earth; our Feeling more eſpecially is ſo Groſs, that we cannot diſtinguiſh betwixt the Reſiſtence of one Body, and another, even where it is extremely Different; and therefore there is no wonder, if it is not capable of Informing us in the Reſiſtence of the Æther; tho' our Feeling our ſelves to Exiſt, as

to

to the External Parts of our Hands and Faces, may poſſibly proceed from the Gentle Impulſe of the Surrounding Space, which we do not take Notice of however, becauſe the Perception is ſo Conſtant, as a Man ſcarcely feels the Cloathes he Wears, unleſs when he ſets his Mind to reflect upon thoſe Perceptions; it is yet very Evident we can feel Cold and Heat, which are nothing more than Different Modifications of the Fluid we are Defending, as they are of Water; And indeed, when thoſe Qualities of Affecting us are Abſent, I do not ſee, that we ſhould have any Manner of Senſe without us; That is, if there were no Action at all of Space or Æther upon our Organs, we could neither See nor Feel, nor have any other Senſation.

2*d.* If Body Exiſted in Abſtracted Space, that Abſtracted Space, or Extenſion, will be Commenſurate to Body or not, for Inſtance, a Globe of ſuch Space to a Globe of Gold of Equal Length, Breadth, and Depth; If Commenſurate, it will be Diſperſed thro' every Part of the Gold, that is, it will Enter into each Point of it, and conſequently, ſince the Extenſion of Gold does not only conſiſt in Length, Breadth, and Depth, but in Thickneſs too, the Globe of Space or Æther will be as Thick, ſeeing it is Commenſurate to it, as the Gold it ſelf, which will not only Cauſe a Penetration of Dimenſions, which this Philoſophy denies, but is contrary to it's own Notion of Space or Æther; If it is not Commenſurate to it, then there will be ſome Parts of Gold, which do not Exiſt in Space, which is again Contradicted by the ſame Philoſophy: But if Body does not, nor cannot Poſſeſs Space, or Enter into it's Dimenſions, that is, ſuppoſing them both to Retain their own Natures, *viz.* Gold and Æther, Then is Real Space or Extenſion Equally Impenetrable with Body.

I ſay ſuppoſing them both to Retain their own Natures, for if they do not, there may be a Penetration of Dimenſions, in one Senſe, ſince a Penetration of Dimenſions may be ſaid to be either,

1*ſt.* When the Dimenſions of one Body Penetrate into thoſe of another, and at once that other Preſerves it's own Dimenſions; This Penetration is Impoſſible in all Matter, and Space or Real Extenſion, Equally; for it is no more than to ſay, the one Body cannot be it ſelf, and another, at the ſame Time, that is, It Excludes all Things from being, what It is.

2*d.* A Penetration of Dimenſions may be ſaid to be, when the Dimenſions or Bulk of one Body not Porous are contrived into the Bulk or Dimenſions of another, which is likewiſe not Porous, without any Increaſe of the Length, Breadth, and Depth of ſuch Bodies; That is, when a Globe of Gold not Porous, for Example, is Compreſſed into another of Equal Bigneſs not Porous without any Alteration of the Magnitude of the Globe, and with only a Change of the Denſity of it; This Penetration of Dimenſions we ſay is poſſible, and that Matter is not Impenetrable in this Senſe, and therefore not Real Extenſion; Becauſe we take all Matter and Space, as they are Real in Nature, to be nothing elſe than Different Combinations, Compoſitions, or Congeries of Actions, which Actions are Reſolved into the Various Degrees and Aſſemblages or Compoſitions of the Expanſive and Contractive Forces, which, however Diverſified, may and do ſubſiſt in the ſame Abſtracted and Similar Space.

Solidity and Reſiſtence is likewiſe Abſtracted, or Real, the Former is a Creature of the Mind, the Latter, what we find in Nature.

§. 3. Third, Solidity, or Reſiſtence, or Firmneſs, as Extenſion, is commonly no more than an Abſtracted Idea Formed by the Mind, and is generally Reputed to be the ſame in all Bodies, the Dullneſs of our Perceptions not allowing us to diſtinguiſh it; whereas, in Truth, there is as much Difference, as in Colours themſelves, or any other the moſt Variable Property in Matter; Solidity, as it is an Excluſion of all Matter from that Place, or Space, which it takes up, is one Thing in all Sorts of Matter, and admits of no Change, This we conſidered under the Head of Impenetrability; But that, which we ſpeak of now, is of a Different Nature; Namely, 'tis that Degree of Force, Reſiſtence, or Action, which any Body obtains againſt the Actions or Violences of other Material Beings; Nor does this Solidity only reſpect the Reſiſtence of a Body to any other Matter Penetrating into the Space it is forced to Leave, but Penetrating into the ſame Space, which it Poſſeſſes, I mean into the ſame Length, Breadth, and Depth, *i. e.* not only it's Oppoſition to Removeing out of it's

Place, but it's Oppoſition to the being Contracted or Condenſed into a Leſs, tho' it was ſuppoſed to have no Pores or Vacuities before ſuch a Condenſation; For if Water could be Compreſſed into a Nineteenth Part of the Space, which it Poſſeſſes, it is not certain, but it would be as Solid as Gold; and tho' we have no Methods, by which we can Effect ſuch a Compreſſion, or indeed any Compreſſion at all, it is not Evident, whether Nature by it's Two Great Inſtruments of the Expanſive and Contractive Forces, or by Heat and Cold, may not do it.

§. 4. THAT Real Space or Extenſion has a Reſiſtence may be Proved by Experiments from *Galileus's Syſtema Coſmicum*, which are Known and Common; For a Stone may be thrown farther than Cotton; An Arrow projected Lengthways will go farther, than one Tranſverſely; On the Contrary, the Wind blowing carries away the Tranſverſe one, and leaves the other; Agitate the Air, as much as poſſible, with a Fan or Napkin in a Narrow Room or any other, bring in immediately the ſmalleſt Candle imaginable Lighted, or the fineſt Leaf-Gold, and there will be no Motion Apparent, the Air in that Inſtant Returning to it's Reſt, which is an Argument of it's Reſiſtence; The Clouds, which hang in the Air, when they come Lower, fall into Rain, which may be, becauſe, tho' there is a Reſiſtence, yet there is not enough to ſupport them; In Rideing, the Air Acts with Violence upon our Faces; Air is apt to carry the lighteſt Things with it, but not the heavieſt in it's Motion, and Atoms Swim every where in it's Subſtance, when a Feather Sinks; If the Earth Moves round it's Axis, it muſt carry the Air and all Projectiles with it, which Demonſtrates a great Force in the Air, for, if it did not thus carry Them, a Bullet ſhot Upwards would not fall in the ſame Place, nor a Stone thrown Downwards deſcend in a Perpendicular; nor would a Bullet Shot to the Weſt with the ſame Force, as another to the Eaſt, deſcribe Equal Lines, but one as much ſhorter than the other, as the Earth deſcribes a Space from Weſt to Eaſt; If Air therefore has a Force or Action, it has, *à fortiori*, a Reſiſtence; A Globe of Lead will alſo make 600 Returns in a Pendulum, whilſt one of Cotton or Wood will not make above 3 or 4; *Rohault's Vitrea Lacryma*, Broken and Shatter'd to Pieces by the Intruſion of Air, likewiſe ſhews this Action or Reſiſtence; And all theſe Demonſtrations of Fact Equally Extend to one Point of Real Space or Extenſion with another, and as much Evidence a Continuity of Reſiſtence or Action, as the Phænomenons we obſerve in Water of Bodies Sinking and Swiming in it, which yet is Acknowledged to have no Pores or Vacuities, ſo far as the beſt Microſcopes could ever Diſcover.

That Real Space or Extenſion, tho' not indeed an Imaginary or Abſtracted one, has a Solidity or Reſiſtence. Galileus's Syſtema Coſmicum.

§. 5. DR. *Wallis* Endeavours to compute the Air's Reſiſtence to all Projectiles by this Lemma, as the moſt Rational that occurrs; That the Reſiſtence of the Air is Proportional to the Celerity, for in a double Celerity, there is to be Removed in the ſame Time twice as much Air, which is a double Impediment, in a Treble thrice as much, *&c.* Therefore, according to this Computation, there is Reſiſtence in every Point; And upon this Computation, the *Linea Projectorum* Reſembles a *Parabola Deformed*, which Agrees with Sir *Iſ. Newton*, who makes it a Curve Approaching nearer to an *Hyperbola* than a *Parabola*, upon the Suppoſition of ſuch a Perpetual Reſiſtence; He alſo tells us, that a Viſcous Medium ſhall more Reſiſt than one more Fluid, tho' of like Intenſive or Specifick Gravity; That a Sharp-Headed-Arrow finds an Eaſier Paſſage, than an Obtuſe or a Blunt one, thro' the Medium, and the ſame Pyramid with the Point, than with the Baſe forward; That Different Mediums equally Liquid, and other Circumſtances alike, Reſiſt in Proportion to their Specifick Gravity, becauſe there is a Heavier Medium to be Removed by the ſame Force; That the Heavier Projectile being once in Motion, and being Equally Swift, and all other Circumſtances the ſame, Moves thro' the ſame Medium more ſtrongly than a Lighter, in Proportion to it's Intenſive Gravity, the Force being Greater in Proportion for the Removal of the ſame Reſiſtence; All which can be no otherwaies Accounted for than by ſuppoſing, that there is a Continued Action or Reſiſtence in Real Space or Extenſion, and which we alſo Defend, that there is an Innate Contractive Force in Heavy Bodies, which makes them Act with a Greater Moment againſt the Expanſive of Air or Æther, than Lighter or more Expanſive ones.

The Continued Reſiſtence or Action of Real Space or Extenſion Acknowledged by Dr. Wallis *and Sir* Iſ. Newton *in their Notion of Projectiles.* Lowthorp's Abridgement of Philoſoph. Tranſact. Vol. 1. Pag. 572. Sir Iſ. Newt. Princip. Prop. 10. Schol. Lib. 2.

Dr. Wallis Philoſ. Tranſ. Pag. 545. Vol. 1. Lowthorp's Abridgm.

Dr. *Wallis* farther tells us. 1. *Si vis ut* V *moveat Pondus* P, *vis* mV *movebit* mP, *cæteris paribus, puta per eandem Longitudinem, eodem Tempore, h. e. eadem Celeritate:* Therefore the Reſiſtence is Equable, if that Computation proceeds juſtly.

2. *Si vis* V *movere poteſt Pondus* P *Celeritate* C, *vis* mV *movebit vel* P *Celeritate* mC, *vel Celeritate* C *Pondus* mP, *vel quodvis* P *ea Celeritate, ut factum ex Pondere & Celeritate ſit* mPC, *atque hinc dependet omnium Machinarum pro facilitandis Motibus conſtruendarum ratio,* viz. *ut quâ ratione augetur* P, *eâdem minuatur* C, *quo fiat, ut*

$$V . PC :: V . mP \times \frac{1}{m} C = PC.$$

3. *Celeritatis gradus ſunt Longitudinibus eodem Tempore tranſactis proportionales, vel Temporibus in eâdem Longitudine tranſactis reciprocè proportionales*; Either therefore there is no Reſiſtence at all, or an Equable one.

4. *Impingentia corpora reſilient ab invicem, ſi Impetus ex vi Reſtitutivâ vel Elaſticâ ſit progreſſivo major.*

5. *In motibus acceleratis & retardatis Impetus pro ſingulis momentis is reputandus eſt, qui gradui Celeritatis tum acquiſito convenit; ubi per curvam fit motus, directio motûs ea eſt, quæ Tangentis; ſi acceleratus Motus ſit & per curvam, Impetus in ſingulis punctis erit ut acceleratio & obliquitas Tangentis; hic motus Pendulis competit.*

6. *Impetus obliquè Impingentis eſt ad ejuſdem Impetum, qui eſſet, ſi directè Impingeret, cæteris paribus, ut Radius ad Secantem Anguli Obliquitatis; Et eadem eſt ratio Gravitationis Gravium obliquè Deſcendentium ad eorundem perpendiculariter Deſcendentium Gravitationem*; Therefore, as in oblique Deſcents on the Surfaces of Water, ſo in Air Motion is more Retarded; and in General, it is Plain, that a Continued Reſiſtence in Æther is ſuppoſed by theſe Philoſophers.

The Continued Reſiſtence or Action of Real Space or Extenſion Acknowledged by Sir Chriſtopher Wren, Hugens, Bernoulli, *and* Leibnitz, *in their Notion of the Velocities of Bodies in their Mutual Occurſe and Impulſe, or the Motion of them in Curves, or in their Elaſticity.* Philoſoph. Tranſact. Pag. 547, 548. Vol. 1. Lowthorp's Abridgm. as alſo, Pag. 550, 551, 553, 554.

§. 6. Sir *Chriſtopher Wren* ſays. 1. *Velocitates corporum propriæ & maximè naturales ſunt ad corpora reciprocè proportionales*; Therefore there muſt be a Reſiſtence, beſides what Ariſes from their own Gravity; for the *Vires acceleratrices* to the Center are owned to be alike in both the Bodies, the ſame or an Equal Force therefore will change both the Bodies from that Determination, and ſince they take another, which is Reciprocally Proportional to their Bulks, there muſt be as much Reſiſtence, as if they were Reſiſted in every Part; and conſequently is to be Attributed to the Medium, thro' which they Move; For the Acceleration of the Parts in either Bodies is owing to one and the ſame Force, and therefore it is one and the ſame Force, which will alter that Acceleration.

2. *Corpora habentia proprias Velocitates etiam poſt Impulſum retinent proprias.*

3. *In Colliſione Corporum, ut in Librâ ſuper Bina Fulcra vel Centra,* 2 *Corp.* 1 *Corp.* :: 1 *Veloc.* 2 *Veloc.* therefore, if they meet *permutatis velocitatibus*, they are the ſame ſtill, if both Acted with Equal Force.

4. *Corpora Improprias Velocitates habentia ex Impulſu Reſtituuntur ad Æquilibrium.*

Hugens tells us in his *Regulæ de Motu Corporum ex Mutuo Impulſu.* 1. *Si Corpori quieſcenti duro aliud æquale corpus durum occurrat, poſt contactum, hoc quidem quieſcet, quieſcenti verò acquiretur eadem, quæ fuit in Impellente, Celeritas.*

2. *At ſi alterum illud Corpus æquale etiam moveatur, feraturque in eâdem Lineâ rectâ, poſt contactum Permutatis invicem Celeritatibus ferentur.*

3. *Corpus quâmlibet magnum à Corpore quâmlibet exiguo & qualicunque celeritate Impacto movetur. Quæ eſt Regula Generalis Determinandi Motum.*

4. *Quantitas motûs duorum Corporum augeri minuivè poteſt per eorum Occurſum, at ſemper ibi remanet eadem quantitas verſus eandem partem, ablatâ inde quantitate motûs contrarii.*

5. *Summa productorum, factorum à Mole cujuſlibet corporis duri ductâ in quadratum ſuæ Celeritatis, eadem ſemper eſt ante & poſt Occurſum eorum.*

6. *Corpus durum quieſcens accipiet plus motûs ab alio corpore duro ſe majori minorivè per alicujus tertii, quod mediæ fuerit quantitatis, interpoſitionem, quàm ſi percuſſum ab eo fuiſſet immediatè, & ſi corpus illud interpoſitum fuerit medium proportionale inter duo reliqua, fortiſſimè omnium aget in quieſcens.*

7. *Conſiderat Hugenius Corpora ejuſdem materiæ, ſive cujus Moles Æſtimatur ex Pondere.*

8. *In Corporibus Sphæricis demonſtrare ſe poſſe ait, (& videtur ipſi eandem eſſe Naturæ Legem reliquis omnibus, ſive Duris, ſive Mollibus, ſive directè, ſive obliquè Occurrentibus) Centrum commune Gravitatis duorum vel quotlibet Corporum æqualiter ſemper promoveri verſùs eandem partem in Lineâ rectâ ante & poſt Occurſum.*

All which Laws or Rules do either ſuppoſe no Action or Reſiſtence in Space at all, or an Equable and a Continued one; If the Firſt, they are mere Abſtracted Notions, and do not Explain, what the Real Motion of Bodies is from Mutual Impulſe; If the Laſt, That Reſiſtence and Action in all the Parts of Space is Confeſſed, which we Contend for.

It is farther ſaid by Others. 1. *In Cycloide Grave quodlibet cadens ex quovis ejùs puncto attingit fundum eodem tempore, quo eum attingeret, ſi caderet ex quovis ejuſdem puncto alio.*

2. *Globulus ſuſpenſus è funiculo juſtæ longitudinis, & intra duas Cycloides vibrans, movetur in Cycloide, ergo vibrationes ejuſmodi ſunt Synchronæ*; This is Demonſtrated by a Perſon of Quality; And the ſame by *Hugens* in his *Horolog. Oſcillator.*

3. That an Heavy Body Deſcends Quicker in a Cycloid Drawn, than in a Right Line Drawn, betwixt Two Points, not in the ſame Vertical Line, but Unequally diſtant from the Horizon; This is Proved from *Bernoulli's Probl. pag.* 551. and another *Probl. pag.* 553. and is ſhewn by Dr. *Keill* in his *Introd. ad Ver. Phyſic. Lect.* 15. *Pag.* 221. *Lemm. Edit.* 3.

4. *Leibnitz, Pag.* 554. *Philoſ. Tranſact. Abridged, Vol.* 1. ſays, That a Spring being Bent to the ſame Degree, will always Unbend it ſelf in the ſame Time, Provided it find the ſame Freedom of Unbending it ſelf ſuddenly, which Proves there is a Reſiſtence or Action in Space: And all the foregoing Propoſitions Evince it, or elſe, that they are merely Abſtracted and Mathematick Reaſonings without giving us any Explication of the Actions and Forces in Nature.

§. 7. That *Des-Cartes* makes the Particles of his Celeſtial Matter, by being Reflected from the Surface of the Earth, to drive down into their Places thoſe Terreſtrial Bodies, which they find above them, §. 20, 21, 22, 23. of his laſt Book of his *Principia Philoſophiæ*, is known.

A Continued Action or Reſiſtence in Space Acknowledged by Philoſophers in their Accounting for the Deſcent of Heavy Bodies. Philoſ. Tranſ. Pag. 560. Vol. 1. Lowthorp's Abridgm. & Pag. 561.

Dr. *Halley* Anſwers: 1*ſt*. That his Obſcurity in §. 23. is an Argument of his Confuſed Idea of Gravity. 2*d*. That it is unlikely, that a Body moving Downwards ſhould be ſo moved by an Impulſe Upwards. We do not here Defend *Des-Cartes's* Account of Gravity, only ſhew, that Philoſophers have Thought a Continued Action in Space no Inconceivable Thing.

Dr. *Voſſius* Aſcribes it to the Diurnal Rotation of the Earth.

Dr. *Halley* Anſwers: 1*ſt*. That there is Demonſtration, that Bodies, circularly Moved, Recede from the Center of their Motion, and if not kept faſt by ſuch a Principle, as Gravity, would be caſt into the Air in a Tangent. 2*d*. That the Effect of this Principle of Gravity is nearly Equal every where, or rather Leſs towards the Equinoctial than towards the Poles, as very certain Experiments Evince, whereas, where the Motion was Swifteſt, the Effect would be the moſt Conſiderable; which is a Proof, either that the Weight of the Air does contribute to Gravity, or that Bodies being Moved in a Circular Motion with the Air, have a leſs Circular Impreſſion to hinder their Deſcent near the Poles than near the Equinoctial: So that let us take Dr. *Voſſius*, or Dr. *Halley*, there is an Action Acknowledged in Space, and a Continued one.

Others Aſſign the Preſſure of the Atmoſphere.

Dr. *Halley* Anſwers. 1*ſt*. That the Atmoſphere's Preſſure is it ſelf from it's own Gravity. 2*d*. That the Preſſure of the Upper Parts of the Atmoſphere, by bending the Springs of the Lower, give the Lower a Force of Reſiſtence Equal to the Bearing or Compreſſive Force of the Upper, having of it ſelf no Force at all. 3*d*. That 'tis unlikely there ſhould be any Deſcent of a Body by the Intervention of the Atmoſphere, becauſe there is an Equal Preſſure of it Upwards and Downwards. 4*th*. By a plain Experiment a Feather in *Vacuo* Deſcends with near the ſame Velocity as a Stone, from which it is Evident, that the Atmoſphere is ſo far from being the Cauſe of Gravity, that it hinders it's Effect; becauſe the Atmoſphere is nearly of the ſame Specifick Gravity with a Feather, but the *Vacuum Boylianum* is not, which ſhows, that in Air there is Gravity and Reſiſtence, or that there is an Action every where, and Diſperſed thro' every Point of Space.

Again, Others make the Earth Attract as a Loadſtone.

To which He Anſwers, That the Loadſtone Attracts only in and about it's Poles, but the Earth near Equally in all it's Parts.

Lastly, Others Aſſign a Sympathetical Attraction betwixt the Earth and Bodies, whereby they have, as it were, a Deſire to be United to it.

He Anſwers *1ſt.* This is to ſay, that Bodies Deſcend, becauſe they Deſcend. *2d.* Beſides, a Feather would then Deſcend with the ſame Appetite, or Deſire, as a Stone. He afterwards tells us, what the Properties of Gravity are, according to the New Syſtem, which we have before Inquired into in our Account of the Phyſical Aſtronomy. He ſays;

First, By this Principle the Earth and all the Heavenly Bodies are kept from Diſſolution, ſo that any Part of them cannot Recede far from the Reſpective Centers, and tho' violently thrown from them they ſtill Tend to be Re-united. But this Doctrine of the Projectile and Gravitating Force has been already Examined, and if it had not, what is This, unleſs the Sympathetical Attraction he before Condemns?

Second, That all Bodies Deſcend towards a Point, which either is, or is very near the Center of the Earth, conſidered as a Globe, to which it Approaches, being Really a Spheroid. Which Center we have before Denied and Confuted, as well as the Earth's being a Spheroid.

Third, That the Center is fixt, becauſe, if it Changed it's Place, the Low-Lands of that Side of the Globe, to which it Approached, would be over-flown, and the oppoſite Side exhibit New Iſlands; but the Iſlands of the Mediterranean, near which the oldeſt Writers Lived, are much what they were in their Times, and therefore no Alteration of the Center; That the Univerſal Deluge is beſt Accounted for by an Approach of the Center to the Parts of the then Habitable World, which, if it were only a 2000*th* Part of the Radius, would be ſufficient to Drown the Higheſt Hills. All which is Calculated and Affirmed upon the Suppoſition of the Truth of the Phyſical Aſtronomy, which is Diſputed.

Fourth, That in all Parts of the Surface of the Earth, as well as in all Points Equidiſtant from the Center, the Force of Gravity is nearly Equal; That the French Obſervers near the Equinoctial, and Himſelf at St. *Helen*'s 16 Deg. South Lat. have found however, that it is there neceſſary conſiderably to ſhorten the Pendulum to make it vibrate Seconds; He thinks this Proceeded from the Height of the Place above the Sea, where the Gravity being Diminiſhed, it was Requiſite to ſhorten the Pendulum in Proportion; but this we have Conſidered and Refuted in the Firſt Book of the Preſent Philoſophy.

Fifth, That the Impediment being Removed, as in the Experiment of the Feather in *Vacuo*, the moſt Compact and moſt Looſe, the Greateſt and Smalleſt Bodies, Deſcend the ſame Spaces in Equal Times; Which, together with the former Property, ſhews the Difference betwixt Gravity and Magnetiſm, this Affecting only Iron, and towards it's Poles; Hence 'tis ſaid to be Evident, that there is no poſitive Levity, that Cork, which Swims on Water, or a Feather in the Air, can no more be ſaid to be Light than Iron, which Swims on Mercury, they are only Bulk for Bulk, not ſo Heavy as the Fluid they Swim in; This is Contradicted by our Doctrine of the Expanſive and Contractive Forces; However Air is here Confeſſed to be as much a Fluid, as Water, and as Water has no Vacuities, ſo neither is it neceſſary, that Air or Real and Material Space ſhould have.

Sixth, That this Power Increaſes as we Deſcend, and Decreaſes as we Aſcend, in Proportion to the Squares of the Diſtances from the Center Reciprocally, ſo as at a Double Diſtance to have but a Quarter of the Gravity; *Vid. Miſcell. Curioſ. Vol.* 1. *Pag.* 14. Upon this Principle, Sir *Iſ. Newton* is ſaid to have made out all the Phænomenons of the Celeſtial Motions; And it is thought to be very Rational, that the Attractive or Gravitating Force ſhould Exert it ſelf more in a Small Sphere, and be weaker in a Larger, but the Surfaces of Spheres are as their largeſt Circles, *i. e.* as the Squares of their Radii, therefore this Force will be Diffuſed in Larger Spheres, and Contracted in Smaller; That is, in Proportion to the Squares of the Radii, and will be always Equal upon the Surface of the ſame Sphere; We have in another

Place Examined into the Truth of this Reaſoning, and ſhall only Obſerve, that it is therefore here again ſuggeſted, that the Action or Force is not Inherent in Bodies, but in the Spaces they Paſs thro', which have Different Actions, as they are at Different Diſtances from the Earth; and according to the Different Diffuſions of Space, that the Action is variouſly Diffuſed thro' it; which is a plain Aſſertion of an Action or Force Continued thro' every Point or Portion of it.

Seventh, That Bodies, tho' they really Tend to the Center, Deſcend in Parallel Lines, the Difference being ſo Small, as by no means to be Diſcovered; And therefore a Reſiſtence or Force in Æther may really be, where it is not Diſcernible; nay it is Evident by this Philoſophy; for Gravity, which is a Reſiſtence or Force, tho' it Increaſes and Decreaſes, as in Property the *6th*, yet is not ſenſible in Projects or Deſcending Bodies, becauſe they fall from a ſmall Height; and all Bodies upon the Surface of the Earth Gravitate to each other, which no one could ever yet Perceive.

A Continued Force, Reſiſtence, or Action in Space Confeſſed by Philoſophers in their Accounts of the Velocities of Falling Bodies. Philoſ. Tranſ. Pag. 563. Vol. 1. Lowthorp's Abridgment.

§. 8. This Action, or Force, in all Parts of Space is likewiſe Confirmed from Thoſe Accounts, which Philoſophers give us of the Velocities of Deſcending Bodies.

First, The Velocities of falling Bodies are ſaid to be Proportionate to the Times from the Beginning of their Falls; Suppoſe a Body has the Velocity of 32 Feet at the End of 1″ of Time, it will have Double of 32 Feet at the End of 2″, Triple at the End of 3″, becauſe, each 1″ of Time, a new Velocity is added Equal to the Former from the ſame Power of Gravity continually Acting thereon; ſuch Force therefore cannot be Inherent in Bodies, but in the Space they Paſs thro', or in the Earth, for Body could not Increaſe it's own Force or Velocity, but, in every Point of Extenſion being ſtill thruſt Downwards with an Equal Action, it muſt continually Acquire a new Velocity Proportional to it's Progreſs; If then this Power or Force Exiſts in Space, we have what we Contend for; If in the Earth, It is neceſſary, that it ſhould be Diffuſed from thence thro' all Space, wherever Gravity Prevails, otherwiſe Bodies could not be Affected by it; And take which we will, a Continued Action or Force is owned on both Hands to Reſide in the Univerſal Expanſe, if there is an Univerſal Gravitation thro' it.

Second, The Spaces Deſcribed by the Fall of a Body are as the Squares of the Times from the Beginning of the Fall; For they are as the Areas of Triangles, which are as the Squares of their Homologous Sides, therefore as 1. 4. 9. 16. &c. and the Differences, according to *Galileus*, as 1. 3. 5. 7. &c.

Third, The Velocity, which a falling Body Acquires in any Space of Time, is Double to that, wherewith it would have Moved thro' the Space Deſcended by an Equable Motion in the ſame Time, *i. e.* the Velocity of falling Bodies is Double to that, which in the ſame Time would have Deſcribed the Space faln thro' by an Equable Motion.

These Three foregoing Propoſitions depend upon this, that in every Moment of Time there is a Triangle Produced by this Velocity, becauſe what Law obtains in Larger Spaces, the ſame does in Smaller and even in the Minuteſt, and which have been before Conſidered in Book the Firſt of this Philoſophy.

Fourth, All Bodies, on or near the Surface of the Earth, in their Fall Deſcend ſo, as at the End of the firſt *2d* of Time they have Deſcribed 16 Feet 1 Inch *London* Meaſure, and Acquired the Velocity of 32 Feet 2 Inches in a *2d* of Time; Becauſe it is Demonſtrated by *Hugens*, *25th Prop. Part 2d. Horol. Oſcillat.* That 16 Feet 1 Inch is the Deſcent of a Body in a *2d* of Time, and by *Prop. 3d.* the Velocity will be Double thereto; and near to this it hath been found by ſeveral Experiments; near, becauſe the Swiftneſs of the Fall hinders us from Determining exactly it's Quantity, and which Difference perhaps may be owing to the Reſiſtence or Action of the Medium.

A Continued Action or Reſiſtence in Space Acknowledged by Dr. Halley, Sir Rob. Moray *&c. in their Doctrine of Projects.*

§. 9. From theſe Four Propoſitions, all Queſtions concerning the Perpendicular Fall of Bodies are ſaid to be eaſily Solved, and the Doctrine of Projects likewiſe Deducible, If we Aſſume the Two following Axioms.

1ſt. That a Body, ſet a-Moving, will Move on Continually in a Right Line with an Equable Motion, unleſs ſome other Force or Impediment Intervene, whereby it is Accelerated, or Retarded, or Deflected, which depends upon this, that Matter is perfectly Paſſive; But this Axiom we are not willing to Allow; becauſe we form our

Philoſ. Tranſ. Pag. 563. 565. 571. 580. 583. Lowthorp's Abridgm. Dr. Halley, Pag. 563.

our Notions of Matter from what we Generally Perceive, and the Generality of Matter being of a Sluggiſh and Groſs Nature, we from thence Conclude that all is ſo; whereas there are a Thouſand Inſtances of Fire, Spirituous Liquors, Vegetables, *&c.* which are not ſo, and even the groſſeſt Parts of Matter have Properties, according to this Philoſophy, more Active, than what our Senſes Inform us of, as, the Gravitation of one Portion of Matter to another, and Others, which are diſcernible by our very Senſes, which no ways Agree with a Paſſive Nature, as Elaſticity or Springineſs, Vegetation, *&c.*

2d. That a Body, being Agitated by Two Motions at a Time, does by their Compounded Forces paſs thro' the ſame Points, as it would do, were the Two Motions Divided and Acted ſucceſſively, or, that the Diagonal is Compounded of the Sides of a Parallelogram; This Axiom has alſo been Examined into, Book the Second, and the Objections againſt it need not be Repeated here. However it is Affirmed;

Pag. 565.

First, That the Motion of all Projects is in the Curve of a Parabola, becauſe the Project is Compounded of Two Forces, the Projectile, which, if there is no Impediment, moves Equal Spaces in Equal Times, and is as 1.2,3.4, the other Deſcending, and is as the Squares of the Times, or as 1.4.9.16, which by Axiom the *2d.* meet in their ſeveral Reſpective Points; the Firſt are Parallel to the Ordinates of a Parabola, and the Second to it's Abſciſſes, and the Property of a Parabola is, that the Abſciſſes are in a Duplicate Reaſon of the Ordinates. Since therefore a Parabola ſuppoſes no Reſiſtence, that Deſcents are in Parallel Lines, which may as well be denied as Reſiſtence, and that Bodies without an Impediment move Equal Spaces in Equal Times, whereas the Air Reſiſts, as well as Gravity, it is Plain, that this is nothing elſe than a Mathematick and Abſtracted Reaſoning.

Pag. 571.

Second, That the Force of a Shot is always the Leaſt at the Vertex of the Parabola, and at Equal Diſtances from it, it's Force is always Equal; From whence, according to this Reaſoning, a Bomb ſhall have as much Force, as it ſeems, when it is wholly Spent, as when it Firſt comes out of the Mortar; ſo that, notwithſtanding, This, in an Abſtracted Reaſoning, may be true, when we only conſider the Projectile and Gravitating Force, yet, ſince it is not in fact True, it is Manifeſt, that the Reſiſtence or Action of Space is very Material in the Doctrine of Projectiles, which occaſions ſo Great a Difference from what is Concluded by a Geometrick Deduction.

Third, That in the Elevation of a Mortar; *1ſt.* If very Great, the Bombs fall too Perpendicularly and bury themſelves in the Ground without any Effect, and that therefore the Beſieged unpave their Streets; *2d.* That, if they come more obliquely, they many Times break upon, or near, the Surface of the Earth; From whence it is plain, that there is a Reſiſtence or Action of the Air or Æther, or Real Space, as in other Fluids, in which Heavy Bodies are leſs Obſtructed in their Force, when Projected Perpendicularly, than when Obliquely; *3d.* That by Diminiſhing or Increaſing the Quantity of Gun-Powder, the ſame Effects may be Produced as by a Greater or Leſs Elevation of the Mortar, and to more Advantage; becauſe you know the Force of Gun-Powder, whereas the Elevation is uncertain in Ships, where the Waves are ſo; Which is an Evident Eviction, that the Reſiſtence or Action of the Medium, or Space, has a conſiderable Influence in Produceing theſe Phænomenons, ſince it may be Conquered by a determinate Force of Powder, as well as by the particular Elevation of the Mortar; *4th.* That a Mortar 45° Elevated is little Different, in it's Projection, from one Elevated ſome Degrees above, or Depreſſed below, that Poſition; Which may be Poſſibly, becauſe ſuch an Elevation is in the middle Situation betwixt the greateſt and the leaſt Reſiſtence or Action of the Air or Æther, or Real Space; for in a Perpendicular Elevation probably there is the Leaſt, and in an Horizontal the Greateſt, the Reaſon of which may be, that in an Horizontal all the Parts of the Æther, or Real Space, have an Equal and the Greateſt Gravity, and therefore the Greateſt Action or Reſiſtence; but in a Perpendicular Elevation the Gravity of the Æther, or Real Space, is Diminiſhed upwards, and conſequently the Action or Reſiſtence; Nor are theſe our Concluſions altogether Unjuſtified from Dr. *Halley*, who ſays, That the foregoing Rules would be Rigidly true, were it not for the Oppoſition of the Medium, whereby the Projectile Motion is Retarded, as well as the Deſcent, being not exactly as the Squares of the Times: 'Tis certain Air is to Water in Weight, as 1 to 800 nearly; However in large Shot of Metal, whoſe Weight ſurpaſſes many Thouſand Times that of Air, and whoſe Force is very great in Proportion to the Surface, wherewith they, namely Shot, preſs thereon, this Oppoſition is ſcarcely Diſcernible; For by certain Experiments, in a ſolid Braſs Shot of 4½ Inches Diameter and 14 *l.* Weight, the Ranges above and below 45° were nearly Equal, tho' the under Ranges went rather the fartheſt; In a ſmaller Braſs Shot of about 1½ Inch Diameter, caſt by a Croſs-Bow to 400 Feet, the Force being much more Equal than in the Mortar Piece, the Under Ranges evidently out-went the Upper; So that in the Smaller Shot, tho' the Air's Reſiſtence is to be Accounted for, yet in Larger it may be Neglected, and his Concluſion is; If ſo, it will be Objected, that the Air's Reſiſtence is Leſs towards the Horizon than the Perpendicular; To which he Anſwers, That the Air's Reſiſtence is really Greater, but the Nearer we come to a Perpendicular, the more Direct is the Projectile Motion contrary to the Deſcent, which muſt therefore diminiſh the Force of the Project; To which we Anſwer, That, according to the Mathematick Doctrine, the Projectile Motion muſt be the ſame, any way, as alſo the Gravitating. But this we are Agreed in, that there is a Force, Action, or Reſiſtence in Real Space or Extenſion. We ſhall now Proceed to Sir *Rob. Moray*'s Obſervations.

Sir Robert Moray, Pag. 580.

FIRST, Take leſs Powder than a full Charge, and ſtill Diminiſh it every Charge, and it will throw a Bullet ſtill a ſhorter and ſhorter Way, then Increaſe it, and it will thro' it farther and farther, till it comes to a juſt Charge, when, if you Increaſe it never ſo much, it will be of no Advantage; We ſay, becauſe it's Force is not Infinite to Vanquiſh the Reſiſtence, or Action, of the Air, or Real Space.

SECOND, The Powder and Bullet is to be Rammed home Equally at every Shot, he means in Trials made, to know the juſt Charge of a Piece, tho' the looſer the Powder lies, it Fires the better; We ſay, becauſe the Contractive Force in the Ramming ought to be Equal, to know what the Expanſive Force of the Fire and Powder is able to Effect againſt the Contractive of the Bullet and the Medium, or the Action and Reſiſtence of Lead or Braſs and of Real Space; and the Looſer the Powder is, the Better it takes Fire; Becauſe the Expanſive Force of the Powder is Greater, the Leſs it is Rammed and Contracted together, and therefore more Readily Joins and Unites with the Expanſive of Fire.

THIRD, Powder finding more Reſiſtence from a Bullet Drives it out with Greater Violence, as in Screw Barrels, or where Wedges or wooden Tampions are made Uſe of, (the Deſcription of which he gives *Pag.* 582.) which may Increaſe the Force of the ſame Charge of Powder, till the Piece burſts; The ſame Quality is alſo Experienced in Air, that the more it's Action is Compreſſed or Reſiſted, the Stronger it is, which ſhews, that Real Extenſion has a certain Action or Force with Powder it ſelf; and the Phænomenons on both Hands may be Explained by the Expanſive, Acting againſt the Contractive.

FOURTH, Guns fixt from Recoiling by a certain Weight, laid upon their Carriages or Barrels, will require leſs Powder to Shoot a Bullet the ſame utmoſt Length, than when they Recoil freely; Becauſe none of the Motion or Force is ſpent contrary to the Project, but is wholly Reflected upon it; Or rather, as We ſay, becauſe the Contractive Force is Greater, as in the former Phænomenons, and therefore the Expanſive of the Powder is Increaſed.

FIFTH, If there be the ſame Weight in the Carriage, there will be the ſame Recoil; as if you cut off the Muzle and place it upon the Carriage, the ſame Recoil will be, as when Continued in one Barrel, becauſe there is the ſame Reſiſtence to the Violence of the Powder; Or, according to our Doctrine, becauſe the Action of the Contractive againſt the Expanſive is in both Caſes Equal.

Mr. Greaves, Pag. 583.

MR. *Greaves* Informs us, That a Cylinder-Bore carries with much the ſame Force, other Circumſtances being Equal, as Bullet, Length and Weight of the Piece, with 8, 9, or 10 *l.* of Powder.

THAT a Taper Bore, the Weight an 100 *l.* more, 4 Inches longer, and the ſame Bullet, carries with the ſame Force as the Firſt, with 7 *l.* of Powder.

THAT a Braſs Piece carries thro' all the 3 Butts with 9 *l.* of Powder, and 18 *l.* Bullet of Iron, whereas an Iron one, with 4 *l.* of Powder and 9 *l.* Bullet of Iron only Entered the ſecond Butt, and a Braſs one with 4 *l.* of Powder and 9 *l.* Iron Bullet carried thro' 2 Butts, and with 3 *l.* of Powder almoſt thro' 2 Butts.

FROM whence it ſeems Evident, that the Expanſive Force of the Metal, or the Elaſticity or Springineſs of it, Adds a Force to the Action or Expanſive Force of the Powder; and from the Firſt Experiment, that the Force of Powder does not lie in the Quantity, but in the Specifick Action, or Expanſive Force, of it, as the Gravity or Acceleration of Bodies to the Center likewiſe does, and perhaps it is a General Law of Action; But then it will be Objected, that 3 or 4 Grains of Powder would be as Effectual as 3 or 4 *l.* to which we Anſwer, ſo it will, *Cæteris paribus*, that is, if the Reſiſtence or Contractive Force as Gravity, or any other Reſiſtence or Contractive Force, as the Straitneſs of the Bore, has no greater a Proportion to 3 or 4 Grains, than it has to ſo many Pounds; *viz.* the proper Actions of Bodies are to be only conſider'd in this Caſe, and how the one differs from the other in Quality, Abſtracting from the Quantity, *&c.* Thus for Inſtance, a ſmall Particle or Point of Iron may be probably carry'd as far by 3 Grains, as 9 *l.* by 3 *l.* of Powder, every Thing elſe I ſay being conſider'd as equal, excepting the Specifick Action or Expanſive Force of the Powder, compar'd with the Specifick Reaction, or Contractive, of the Iron. Thus the Specifick Action of a Drop of Water or of an Ocean of it is the ſame.

THESE Experiments however prove the Reſiſtence, or Action, of the Air, or Real Extenſion, ſince there are different Forces of Powder requir'd to carry the ſame Weight a ſhorter Space, or a longer. And ſeeing all the Experiments of this and the foregoing Sections, as well as of the following, Extend to every Point or Portion of Space without Diſtinction, We from thence Affirm, that ſuch Reſiſtence, Force, or Action, is Continued, Uniform, and Uninterrupted.

A Continued Reſiſtence, Force, or Action, in real Space or Extenſion, Acknowledged by Philoſophers in their Notions of Wind-Guns, Jects d' Eau, *Velocity of Air, ruſhing into an Exhauſted Receiver, and of Wind produced by the Fall of Water,* &c. Philoſoph. Tranſact. Vol. I. Pag. 584, 585, 586, 587, 593. Lowthorp's Abridgm. Dr. Papin, Pag. 584.

§. 10. A Ball of Lead may be Caſt to a very great Diſtance by Compreſſion or Rarefaction; *Rohault* deſcribes an Inſtrument for the Firſt, and Dr. *Papin* for the Laſt, and which amounts to this, that if, by certain Methods preſcrib'd, you Compreſs the Air in a Cylinder, it's Action being much greater than that of the External, it will violently Ruſh out, and carry along with it the Lead, which is Included; On the Contrary, if you Extract the Air out of a Cylinder by a Pneumatick Engine, the External Air will be too Powerfull for the Internal, and conſequently drive the Lead thro' it to a great Diſtance; The Effects of Rarefaction are little leſs than thoſe of Compreſſion, or which is all one, the Force of Compreſſed Air, in Reſpect of Common Air, is not much more than the Force of common Air, in Reſpect of the Rarefacted; However from both theſe Experiments it is Manifeſt, that there is a vaſt Reſiſtence, Force, or Action in the Air, or in real Extenſion, and that ſuch Force, or Action in General, is Uninterrupted and Continued in it, ſince theſe Experiments Obtain in any Parts or Parcels of Space whatſoever; Theſe likewiſe are Inſtances of the Expanſive and Contractive Forces in Nature, for Common Air, Contracted becomes more Expanſive, and in its natural State is Expanſive, which Power we may ſuppoſe it Derives from the Expanſive of the Sun, as, what it has of the Contractive, is from the Earth, the Moon, and the Planets.

Dr. Papin, Pag. 585.

FIRST, In Order to Compute the Velocity of Air Ruſhing into an Exhauſted Receiver, or Wind-Gun, we are told, that *Jects d'Eau* riſe not ſo high, as their Source, by Reaſon of the Reſiſtence of the Medium, tho' they have originally a Force or Swiftneſs, which would carry them to that Height, being an Hydroſtatical Principle; Which may be Explain'd from the Expanſive and Contractive Forces; For if Water, for Inſtance, has a Comparative Expanſive Force in Reſpect of the Earth, which has a Contractive, the Parts of it, if permitted, will Riſe to the ſame Height from it, whilſt the Reſt are equally Balanced with one another.

SECOND, From which Hydroſtatical Principle this Propoſition is Deriv'd, That of Fluids equally Preſs'd the Lighter riſes higher than an Heavier, in the ſame Proportion as one is Heavier than the other, that is, the Height is in a Reaſon Reciprocal to the Weight; Which may be likewiſe Explained from the Expanſive and Contractive Forces; For the Lighter any Body is, the more Expanſive is it's Force, and the farther it will Recede from the Contractive of the Earth; Thus Spirituous Liquors, and Fire, will riſe higher than in a Reciprocal Proportion to their Weight, by their exceeding Expanſive Force and their Volatility: From this Expanſive Force, is Solved that Phænomenon alſo, which the common Hydroſtaticks cannot do; Namely, Why, upon mixing a Spirituous Fluid with Water, it Diffuſes and Diſperſes it's ſelf thro' it in a Thouſand Undulations, whereas if Lighter, it ſhould Swim at the Top, or, if Heavier, Subſide to the Bottom; The Reaſon of which can be only, that the Expanſive Force Exerts it's ſelf in all Directions, wherever it is oppoſed by the Contractive of the Water, as the Expanſive of Fire or Flame, in the Contractive of the Fuel, which it Surmounts and Vanquiſhes.
